Books

50 Years of LSD: State of the Art and Perspectives on Hallucinogens. A. Pletsher (Ed.). Parthenon Publishing; 1994. A series of papers on the historical, pharmacological, psychopathological, transcultural and clinical aspects of LSD, presented at a conference sponsored by the Swiss Academy of Medical Sciences on the 50th anniversary of the discovery of LSD.

Dark Night, Early Dawn: Steps to a Deep Ecology of Mind. Christopher M. Bache. State University of New York Press; 2000. "With moving honesty and rare lack of inflation, Bache has brought forth a conception of the human psyche that intimately reconnects the personal ordeals and awakenings of the individual to the larger collective suffering and spiritual transformation of the entire human species, at the most crucial of historical thresholds. This is a book to read soon and to integrate carefully." - Richard Tarnas, author of The Passion of the Western Mind: Understanding the Ideas that have Shaped our World View.

The Discovery of Love: A Psychedelic Experience with LSD-25. Malden Grange Bishop. Dodd, Mead & Company; 1963. This book is a detailed and fascinating account of a person's initial encounter with LSD. It also reveals the incredible power of a well planned and well executed psychedelic journey. Beginning in 1961, and stretching over the next three years, the International Foundation for Advanced Study in Menlo Park, California, conducted research with LSD and mescaline, processing some 350 participants. As a historical record, Bishop's book provides an important firsthand account of these experiments from a participant's point of view. To follow a conservative, 54-year-old businessman's transformation into a person who values love above all else in life is a profound testimony to the power of this sacred medicine we call LSD.

The Doors of Perception / Heaven and Hell. Aldous Huxley. Harper Collins; 1954 / 1956. A demonstration of what a refined, prepared mind can do with the opportunity afforded by a psychedelic in observing nature, art, colors, and forms in their full glory, with a profound appreciation of the transpersonal and numinous aspects of life. These books more than any other in their time period encouraged many to investigate the psychedelic experience.

Drawing it Out: Befriending the Unconscious. Sherana Harriette Frances. Introduction by Stanislav Grof, M.D. Prologue and Afterword by Tanya Wilkinson, Ph.D. MAPS; 2001. "I do not know of any single document illustrating the extraordinary healing and transformative potential of psychedelics in a way that matches in its importance this book by Harriette Frances and the unique illustrations that accompany it. Her ability to find artistic expression for the images and depth of her psyche is truly extraordinary!" - Stanislav Grof, M.D., author of LSD Psychotherapy.

Drugs, Set and Setting: The Basis for Controlled Intoxicant Use. Norman Zinberg. Yale University Press; 1984. A pioneering book that illuminated the factors that permit some people to use illegal drugs, including psychedelics, in a controlled fashion.

Ecstasy: The Complete Guide. A Comprehensive look at the Risks and Benefits of MDMA. Julie Holland, M.D. (Ed.). With contributions from Andrew Weil, Ralph Metzner, Rick Doblin, Douglas Rushkoff, Sasha and Ann Shulgin, Rabbi Zalman Schachter, and others. Park Street Press; 2001. "MDMA is a unique compound with great potential for positive use. This is the most complete book about it, with much information to help people realize that potential as well as reduce any possible harm." - Andrew Weil, M.D., author of 8 Weeks to Optimum Health and Spontaneous Healing.

Ecstasy: The MDMA Story. Bruce Eisner. Ronin Publishing; 1994 (second edition). A widely read summary of the history, usage and effects of MDMA.

Entheogens and the Future of Religion. Robert Forte (Ed.). Council on Spiritual Practices; 1997. "Entheogen" is the currently designated name for a psychedelic used for spiritual realization. According to Jonathan Ott, the word is derived from Greek and means "realizing the divine within." Dr. Huston Smith says, "collectively, these essays constitute the best single inquiry into the religious significance of chemically occasioned mystical experiences that has yet appeared."

Exploring Inner Space: Personal Experiences Under LSD-25. Jane Dunlap. Victor Gollancz Ltd.; 1961. Written by a well known scientific authority whose books were so popular the publisher refused to let her use her correct name. Jane Dunlop describes in detail five outstanding experiences under the influence of LSD. More beautifully written and profound descriptions of remarkable LSD experiences probably don't exist.

Gateway to Inner Space: Sacred Plants, Mysticism and Psychotherapy. Christian Rätsch (Ed.). Prism/Avery Publishing; 1989. A collection of essays by many leading researchers in the field of altered states of consciousness. Issues addressed include the medical use of psychedelics, "molecular mysticism," death and rebirth themes in shamanism, comparisons between meditative and psychedelic experiences, and states of tryptamine consciousness.

Hallucinogens: A Reader. Charles S. Grob (Ed.). Penguin Putnam, Inc.; 2002. A collection of essays by and interview with: Lawrence Bush, Gary Fisher, Albert Hofmann, Terence McKenna, Ralph Metzner, Jeremy Narby, Thomas Riedlinger, Glenn Shepard, Huston Smith, Myron Stolaroff, Rick Strassman, Donald Topping, Roger Walsh, and Andrew Weil. A great deal of the misunderstanding regarding the nature of psychedelic substances arises from the fact that the majority of scientists and researchers who have examined these substances in the past have not understood the essential spiritual nature of mankind. This collection of authors are thoroughly familiar with the true potential of psychedelic substances due to their direct personal experiences with them. This is the only way these substances can be properly understood and appreciated. Dr. Grob has assembled a well-informed collection of writings on the nature of psychedelics.

Handbook for the Therapeutic use of Lysergic Acid Diethylamide-25, Individual and Group Therapy. D.B.

Blewett, Ph.D. and N. Chwelos, M.D. 1959. Despite being prepared in the late 1950s, this handbook contains some of the most informed and valuable data available concerning the effective methods of conducting LSD therapy. Available on the www.maps.org website.

The Healing Journey: New Approaches to Consciousness. Claudio Naranjo. Pantheon Books. Random House; 1973. Incisive case reports about the therapeutic use of MMDA, MDA, ibogaine and harmaline. A classic in the field of psychedelic psychotherapy.

Higher Wisdom. Charles S. Grob and Roger Walsh (Eds.). SUNY Press; 2004 (in press). Eminent thinkers reflect on the continuing impact of psychedelics. Contains interviews with Betty Eisner, Ram Dass, James Fadiman, Gary Fisher, Pet e r T. Furst, Stanislav Grof, Micheal Harner, Albert Hofmann, Laura Huxley, Zalman Schachter, Alexander T. Shulgin, Ann Shulgin, Huston Smith, and Myron Stolaroff.

The Human Encounter with Death. Stanislav Grof, M.D. and Joan Halifax, Ph.D. E.P. Dutton; 1977. A remarkable portrait of the experiment in which patients dying of cancer at the Maryland Psychiatric Research Center in Baltimore, Maryland were treated with psychedelic therapy.

The Ibogaine Story: Report on the Staten Island Project. Paul de Rienzo, Dana Beal & Members of the Project. Autonomedia; 1997. An account of the discovery and development of ibogaine as treatment for drug addiction, with a special focus on the political aspects of ibogaine research.

In Search of the Ultimate High: Spiritual Experiences through Psychoactives. Nicholas Saunders, Anja Saunders, and Michelle Pauli. Rider (an imprint of Ebury Press, Random House); 2000. An analysis of the cross-cultural and spiritual implications of altered consciousness produced by psychedelics. Featuring a fascinating collection of the accounts and insights that hundreds of truth seekers around the world have obtained from their thoughtful and reflective use of psychoactives. An excellent book for people who want to know more about the spiritual uses of psychedelics in contemporary society.

Insight Outlook. Albert Hofmann. Humanics New Age; 1989. A personal review of Dr. Hofmann's world view. He describes the early childhood mystical experiences that established his basic understanding. It was his desire to more completely understand the mystery of matter and the miracle of the plant world that led him to chemistry. He chose to work at Sandoz because their chemical explorations involved plant materials, thus leading him more directly to the understanding of nature. The book sets forth the major tenets of his philosophy, which was reinforced by the openings provided by appropriate use of LSD.

Ketamine: Dreams and Realities. Karl Jansen, M.D., Ph.D. MAPS; 2001. "Indispensable reading for those with any interest in ketamine. Entertaining, thought-provoking, and thorough." - Rick Strassman, M.D., author of DMT: The Spirit Molecule.

LSD, My Problem Child: Reflections on Sacred Drugs, Mysticism, and Science. Albert Hofmann. J.P. Tarcher, Inc.; 1983. This book traces how LSD originated, the discovery of its psychic effects, its applications to therapy, and the crushing developments that ensued from the widespread use of LSD as an inebriant. The book describes a number of valuable individual experiences, as well as visits with key figures like Aldous Huxley, Timothy Leary, and others.

LSD Psychotherapy: Exploring the Frontiers of the Hidden Mind. Stanislav Grof, M.D. Introduction by Andrew Weil, M.D. MAPS; 2001. Considered the most complete book on psychedelic therapy, this is a treasure house of all aspects of the work: history, procedures, client preparation, qualifications of the therapist, and more.

Pharmacotheon: Entheogenic drugs, their plant sources and history. Jonathan Ott. Natural Products; 1996 (second edition). The introductory Proemium is a must read for those wishing to understand the current political, social, and scientific dilemmas of psychedelic drugs.

PIHKAL: A Chemical Love Story. Alexander T. Shulgin and Ann Shulgin. Transform Press; 1991. Comprehensive, definitive guide to the psychedelic phenethylamines, such as mescaline and MDMA, and a great love story. Two parts: first the human story of the search for active mind compounds within a marriage of two active minds. Next, detailed catalog of the chemistry, characteristics of action and synthesis of 179 compounds and results of human assay at varying dosages.

Psychedelic Drugs Reconsidered. Lester Grinspoon and James B. Bakalar. The Lindesmith Center; 1997 (third edition). Two of the world's leading experts on drug use provide the general reader with a comprehensive survey of psychedelic drugs and the scientific and intellectual issues they raise. The authors review the chemistry of psychedelics, their effects, and the history of human experience with them as well as assessing the potential value of the drugs. Excellent bibliography.

Psychedelics Encyclopedia. Peter Stafford. Ronin Publishing; 1992 (third edition). Highly readable book on history, background, preparation, chemistry, methods of use, results, and social implications of the known psychedelic drugs.

The Psychedelic Reader: Classic Selections from the Psychedelic Review. Timothy Leary, Ralph Metzner & Gunther M. Weil (Eds.). Citadel Press; 1993. Selections about the therapeutic, religious and legal aspects of psychedelic drugs from the first four issues of the Psychedelic Review (1963-1964), the journal edited by the Harvard psychedelic research team.

Psychoactive Sacramentals: Essays on Entheogens and Religion. Thomas B. Roberts (Ed.). Council on Spiritual Practices; 2001. In 1995, the Chicago Theological Seminary, along with the Council on Spiritual Practices, held a conference to examine the potential benefits and concerns related to employing entheogens in spiritual practice. Speakers included leaders in religion, mental health, research, and allied fields. The views of the participants have now been published in this book, which is a valuable collection of information in an exciting field.

Pursuit of Ecstasy: The MDMA Experience. Jerome Beck, Ph.D. and Marsha Rosenbaum, Ph.D. SUNY Press; 1994. Expanding on a study sponsored by the National Institute on Drug Abuse, the authors present a thorough and trustworthy review of the emergence and spread of MDMA use, the path toward illegalization, the diverse social worlds and scenes evolved around the use of MDMA and how they result in different experiences, why people use MDMA and what if anything makes them stop, long term benefits and therapeutic potential, adverse reactions and abuse, and recommendations for harm reduction and continuing research of the therapeutic potential.

Realms of the Human Unconscious: Observations from LSD Research. Stanislav Grof, M.D. E.P. Dutton; 1976. A systematic and comprehensive discussion of the transpersonal model of the human unconscious. A uniquely valuable contribution to the field of psychology.

The Road to Eleusis: Unveiling the Secret of the Mysteries. R. Gordon Wasson, Carl A. Ruck, Albert Hofmann. Harvest/ HBJ; 1978. Three scholar-scientists document their theory of the LSD-like component of the religious rites at Eleusis, celebrated for 2,000 years.

Shivitti: A Vision. Ka-Tzetnik 135633. Gateways Books; 1998. An autobiographical account of a concentration camp survivor's experiences with LSD psychotherapy, conducted in Holland by Professor Bastiaans. Very moving and illustrative of the processes of LSD psychotherapy.

Storming Heaven: LSD and the American Dream. Jay Stevens. Harper Collins; 1987. A thorough, well written, intensively researched history of the advent of psychedelics on the American scene. With each new aspect introduced, the author traces back to the roots of that development, and shows how it progresses to intertwine with the overall picture.

Thanatos to Eros: Thirty-five Years of Psychedelic Exploration. Myron J. Stolaroff. VWB-Verlag für Wissenschaft und Bildung; 1994 (see page 166 for complete description).

This Timeless Moment. Laura Huxley. Mercury House; 1991. A personal account of Aldous Huxley's last years by Laura, his wife, including details of the outcome of his request to be administered LSD while dying. Profoundly inspirational.

TIHKAL: The Continuation. Alexander T. Shulgin and Ann Shulgin. Transform Press; 1997. A continuation of the Shulgin's popular book PIHKAL: A Chemical Love Story. The first part of the book blends travel, botanical facts, scientific speculation, psychological and political commentary. The second part describes in detail a wealth of tryptamines, plus appendices presenting topics such as cactus alkaloids, natural beta-carbolines, current drug law, and all known tryptamines that might be psychedelic. Once again the Shulgins honor us with an outstanding collection of vital information, particularly for those interested in the psychedelic field.

The Varieties of Psychedelic Experience. R.E.L. Masters and Jean Houston, Ph.D. Delta; 1966. A research-based comprehensive review of the effects of LSD on human personality, along with a section on the role and training of the guide.

Print Resources

Ambrosia Books & Academic Publishing (formerly Rosetta Books), HC 71 Box 34, Taos NM 97571. Ambrosia offers quality books, art, and obscure out-of-print research relating to ethnobotany and pharmacology. They are also the publisher of Entheos: The Journal of Psychedelic Spirituality. Edited by Mark Hoffman. Yearly two-issue subscriptions are $28.00 (USA). See website for costs to foreign countries. www.entheomedia.org. Catalog $3.00.

The Entheogen Review, POB 19820, Sacramento, CA 95819. A quarterly journal that acts as a clearinghouse for current underground data about the use of visionary plants and drugs, offering information that is unavailable anywhere else. Edited by David Aardvark and K. Trout. $25.00 (USA), $35.00(foreign). See www.entheogenreview.com.

FS Book Company, POB 417457, Sacramento, CA 95841. (800) 635-8883. A large selection of books related to Cannabis, mushrooms, and psychedelics. See www.fsbookco.com. Catalog is $2.00.

Psychedelic Resource List (fourth edition), POB 19820, Sacramento, CA 95819. Descriptions and reviews of over 650 organizations related to psychedelics. 207 pages. $24.00 (USA), $29.00 (foreign). See www.entheogenreview.com/prl.html.

Bibliographies

The Albert Hofmann Collection: LSD & Psilocybin References
www.erowid.org/references/hofmann_collection.php
In the early 1950s, Sandoz began collecting LSD and psilocybin-related articles as part of Albert Hofmann's work with these substances. For nearly 35 years, Sandoz gathered over 4,000 documents: LSD and psilocybin journal articles from the late 1940s through the early-1980s, a few student theses, newspaper clippings, and other unique items. In the mid 1990s, the collection was given to the Albert Hofmann Foundation, and during the late 1990s, along with the Multidisciplinary Association for Psychedelic Studies and the Heffter Research Institute, they collaborated to create a digital index of the papers. In 2002, representatives from the Erowid web site and from MAPS completed the digital index of this entire collection.

Psycholytic and Psychedelic Research 1931-1995: A Complete International Bibliography
Torsten Passie, M.D., M.A., with preface by Hanscarl Leuner, M.D. Laurentius Publishers; 1997. To order contact MAPS by e-mail at askmaps@maps.org or contact Laurentius Publishers by e-mail at dehmlow@bib.mhhannover.de.

An excellent bibliography on the use of psychedelics in psychotherapy, this work is a valuable guide for students and researchers. A meticulous worldwide search by the author has revealed 687 pertinent scientific publications for further study. Research and therapeutic work with psychedelics remains controversial. The presentation of correct information helps overcome irrational projections, conclusions and prohibitions. Scientific research shows these catalysts can be used effectively and safely in medical psychotherapy.

This bibliography includes a precise subject index organized by substances, settings, methods, treatment results and more. The preface by Professor Hanscarl Leuner (Göttingen University, Germany), the leading European authority on research with psychedelics, provides an expert view. The introduction gives an overview of psycholytic and psychedelic therapy. This document is available as part of the WWW Psychedelic Bibliography, at www.maps.org/wwwpb.

Religion and Psychoactive Sacraments: A Bibliographic Guide
Thomas B. Roberts, Ph.D. and Paula Jo Hruby, Ed.D. (Eds.). Contains over 550 annotated references to books and dissertations which address the topic of entheogens, psychoactive plants, and chemicals used within a religious context. In the view of editor Thomas Roberts, the Guide firmly establishes that theologians, clergy, scholars and laypersons see the topic of psychoactive sacraments as important and worthy of discussion and that disagreement, discussion, and debate exist over the questions: Is there legitimate religious use for psychoactive sacraments, and if so, what is appropriate? The index greatly enhances the usefulness of this booklet. Notes and Excerpts for each book range from half a page to three pages. The books described are almost exclusively in the English language and the emphasis is on North America. The editors note that the vast research in world-wide anthropology is under-represented and deserves a guide of its own. Available online at www.csp.org/chrestomathy.

World Wide Web Psychedelic Bibliography
www.maps.org/wwwpb
This bibliography is designed to systematically digitize and protect the body of valuable psychedelic research papers for posterity. Sponsored by the Multidisciplinary Association for Psychedelic Studies, the Heffter Research Institute and the Albert Hofmann Foundation, this site mainly has annotated and non-annotated bibliographical listings but has some full-text listings. Includes bibliographies for: Psychedelics and the Dying; Psychedelics in Western Culture; Sandoz Pharmaceuticals' collection of research on LSD and psilocybin; Sasha Shulgin's MDMA bibliography; Howard Lotsof's ibogaine bibliography; the Janiger and Paltin bibliography of LSD. This site is frequently updated.

By the Same Author

Thanatos To Eros: Thirty-five Years of Psychedelic Exploration, 192 pages, color hard-back cover, ISBN 3-86135-453-5.
Myron Stolaroff was the founder and President of the International Foundation for Advanced Study in Menlo Park, California, an organization devoted to research with LSD and mescaline from 1961 to 1965. Six professional papers covering this work have been published in appropriate journals.

Early on, Stolaroff was convinced of the value of psychedelic substances, and devoted his career to studying them. This book includes a detailed account of his own personal experiences - coming to grips with an excruciatingly painful birth experience and its impact on his life, and learning to recognize and break free of powerful, oppressive feelings of failure and inadequacy. Facing and resolving repressed material opened the door to discovering the joy and vitality that life has to offer. It is a journey from the grip of Thanatos, the drive for death that effectively defeats enjoyment of life, to Eros, the drive for life that brings ultimate fulfillment.

An essential ingredient in the success of this struggle was the use of psychedelic substances. These sacraments, as he prefers to call them, allowed him to confront and resolve powerful shadow material. More important, they opened the gateway to that level of Divine love and grace that is the source of true healing and the freeing of our ultimate capacities.

Stolaroff's desire to discover effective means for self-realization led him to continue exploring newly discovered substances as long as they were legal. This book describes work done with family, friends, and research volunteers employing MDMA, 2CB, 2C-T-2, 2C-T-7, 2C-E, and others. Numerous experiences are described in detail. Since for many people psychedelic experiences tend to fade if not appropriately utilized, serious consideration is given here to the concentrated effort required to accomplish rewarding changes.

These experiments and the discussions presented shed intriguing light on the nature of psychedelic experiences, the nature of the human psyche, factors affecting rewarding experiences, and aspects of transcendental levels of consciousness. Substantial evidence is presented of the inordinate power of the human mind, unrecognized by mainstream science - a power currently widely misdirected to create human pain and suffering. Numerous trials demonstrate that when used with integrity, skill, and fortitude, psychedelic substances can reveal the unfathomed love supporting all of creation, a love that can dissolve the death grip of Thanatos to free Eros and joyously illumine life in all of its aspects.

"I do not remember that a book from a living author impressed me more than Thanatos to Eros... My accord with your concepts of life and reality can best be summarized if I tell you that already in the first two paragraphs of the Introduction, the core of my belief has found its perfect, most beautiful expression."
- Albert Hofmann, Ph.D., retired Director of the Pharmaceutical-Chemical Research Laboratories, Sandoz Ltd., inventor of LSD.

"Myron Stolaroff is one of the bravest, most sincere and forthright psychonauts of our time... The result is a book which speaks volumes to the psychology and spiritual worth of these substances..."
- Jon Hanna, *Psychedelic Resource List*.

Thanatos To Eros may be ordered from: THANEROS PRESS P.O. Box 773, Dept. SC Lone Pine, CA 93545
Price: $22.95 per copy. Add $3.00 per copy for shipping and handling.

For Air Mail to Europe: add an additional $6.00. California residents add $1.78 sales tax for each book. Please make check or money order payable to: *Thaneros Press*. NOTE: Limited supply available.

About the Publisher: The Multidisciplinary Association for Psychedelic Studies (MAPS)

MAPS President Rick Doblin,

MAPS President Rick Doblin with Leo Zeff

HERE THERE BE DRAGONS JUST six hundred years ago, maps of the known world contained the inscription, "Here there be dragons," indicating terra incognita about which we knew nothing and hence feared to tread. Today we find this viewpoint exceedingly quaint. What changed? Knowledge and information was gathered by souls brave enough to challenge orthodoxy and venture into those uncharted realms inhabited by dragons. They returned with firsthand information that refuted "common knowledge" and led to a revised worldview.

Today, knowledge of our physical environment has expanded beyond belief.

Regarding our inner environment, however, many still fear that "here there be dragons." Replacing fear with understanding will require the use of every tool available, including psychedelic substances, to increase our knowledge of the internal terrain. Unfortunately, using psychedelics to explore these uncharted landscapes was forbidden for several decades.

Recently a few brave scientists have been permitted to make the trek and conduct psychedelic research. Would you like to have access to results of that research, and become part of this continuing "quest for knowledge?"

The Multidisciplinary Association for Psychedelic Studies (MAPS) is a membership-based IRS-approved non-profit research and educational corporation founded in 1986. MAPS pursues its mission by assisting scientists to design, to obtain governmental approval for, to fund, to conduct and to report on research into the healing and spiritual potentials of psychedelics and marijuana. Such uses may include psychotherapeutic research and treatment, treatment of addiction, pain relief, spiritual exploration, shamanic healing, psychic research, brain physiology research and related scientific inquiries.

MAPS publishes a quarterly Bulletin that is sent to all members, as well as to a substantial number of government policy makes and academic experts. The Bulletin features research updates, articles about related issues such as spiritual contexts for psychedelics, book reviews, reports on consciousness and the efforts of organizations with similar goals, and readers' letters. MAPS maintains a website (www.maps.org) which contains all the back issues of the MAPS Bulletin, as well as related documents.

Supporting the MAPS Mission

MAPS serves as a non-profit pharmaceutical company that seeks to develop MDMA, other psychedelics and marijuana into prescription medicines. Now that the FDA is once again permitting scientific research into the risks and benefits of psychedelics and marijuana, your support of MAPS can make a substantial difference in the rate at which the field advances. Rates are:

MEMBERSHIP TYPE	RATE (OUTSIDE USA)
Student/low income	$20-34
Basic	$35-49
Basic Plus (includes a free book)	$50-99
Supporting (includes a free book + water bottle or coffee mug)	$100-249
Patron (includes two free books)	$250+

International members, please add $15 to your membership rate for shipping.

Make check or money order payable to MAPS. Credit card charges add $1.00. We can accept checks made on American banks, international postal money orders, Visa, Mastercard, American Express, or Paypal. MAPS cannot accept foreign checks. See "Ordering Information" on the following page to contact MAPS for memberships and donations.

How to Work with Difficult Psychedelic Experiences

original text:
https://maps.org/resources/responding-to-difficult-psychedelic-experiences/101-how-to-work-with-difficult-psychedelic-experiences

A true psychedelic experience, even a so-called bad trip, is sacred. In earth-oriented, shamanic cultures, even a psychotic breakdown, induced by a psychedelic, is part of the initiation.

So remember the way of the ancients: this is a process, a process of awakening, healing, and ultimately celebrating life.

To avoid psychologizing the psychedelic experience I have avoided medical or traditional therapeutic language.

Overview of what we will cover:

Table of Contents:

1. Role of the Sitter or Facilitator
2. Varieties of Psychedelic-Induced Crises
3. Working and Being with Psychedelic Emergencies
4. Aftercare
5. Related Readings

This is a short overview of the material we will cover in this hands-on training. It is based on 30 years of experience sitting for people. It has therapeutic value, but goes beyond therapy and moves into transpersonal and spiritual realms.

The manual is based on training, schooling, teachings and hands-on work with the leading people in the psychedelic movement, and on in-depth work with healers/shamans from Nepal, Ecuador, and the Navajo nation. It is based on my own healing and therapeutic work, using psychedelics, western psychology, body work, breathwork, art, and different eastern tools, like meditation, Zen koan study and nature work.

1. Role of the Sitter or Facilitator

The work with psychedelics, entheogens, and plant teachers is an area of the healing arts that is ancient and has been rediscovered in the last 100 years. There are many different ways to work with and understand the psychedelic experience. When we work and sit with a person going through a psychedelic-induced crisis, it is important to understand that in a certain way this is a dialectic relationship, a way of relating that is ancient.

Every person is a psychospiritual system, meaning there is no separation of body, mind, emotion, soul, imagination and energy. Therefore it is very important to see each person as a unique individual.

There is always the tendency to overpower the other with our knowledge, wisdom, and insight. So let go of all knowledge regarding the experiences that the person is having. Just be with, listen, and observe. This brings us back to the dialectical relationship, paying full attention, allowing the other to express and communicate whatever they want. Just being, without a putdown or judgment.

It is important for the healer/sitter/helper to believe in her/his way of working. The belief in the method is important for the results.

The healer/sitter therefore is someone who has had their own psychedelic experience and has had some experience sitting for people, guiding her/his friends. Without any experience, it is impossible to just be with someone having a psychedelic experience or guiding someone having a psychedelic crisis. It is good to know that we all have blind spots and there is the danger that we might stop the experience if we have not explored this material or are afraid.

Rule #1, under any condition, is that we honor and respect the person having the crisis.

Even if we don't understand what's happening (the person having the crisis might be much more developed than we are, lost in worlds unknown to us, or reliving a drama we can't comprehend), we serve as an anchor, a resting place, a quiet center. We know that our presence is helpful. At this moment we don't have to solve all the problems and answer all the questions that the experience or the person's life presents.

We have to remember that tens of millions of people have used psychedelics, in many different, sometimes not very supportive, environments, and returned home safely. With support, knowledge, and integrative work there is very little danger in the psychedelic experience itself. Even the most frightening and bizarre behavior, when explored and worked with, will turn out to be beneficial and enlightening.

As stated earlier, the positive outcome of our work requires trusting the wisdom of the ancients, trusting the wisdom of our modern teachers and healers, and trusting the built-in wisdom of our bodies, minds and souls.

We frequently pick up emotions and feelings and energies from others. We will cover ways of clearing, cleansing, and purification.

2. Varieties of Psychedelic-Induced Crises

This is a vast area, so we will just touch on it. For a more in-depth study, see the reading list.

There is no clear manifestation of any substance or mixture of substances. But there are some generalities. It is very important to know the active duration of the different substances. All psychedelics have a similar pattern: there's the doorway with different physical, mental and emotional manifestations. There is a buildup, then an extended stay on a plateau, then the coming down, re-entry.

The most common felt threat to sanity is the feeling/experience that one is going crazy, losing one's mind, or that this will never end. This feeling/experience is supported by changing mental states and powerful (sometimes) changes in perception. Major shifts in ego/personality structure, regarding one's belief and understanding of oneself, the world, and god, are common.

Old traumas can be remembered and relived. These memories can be of a physical nature (reliving one's birth, childhood abuse and/or illness, memories of famine and/or war, accidents, rape are some of the possibilities of re-emergence). These memories can also be of an intellectual, emotional nature (reliving verbal abuse, a lack of basic emotions, body contact, love, nurture, or a disassociation due to a traumatic experience).

These traumas can also be of a transpersonal nature, meaning phenomena that go beyond our personal identity or biographical understanding of the universe. These could be experiences from another life, becoming one with the earth or other life forms, or experiencing the life cycle of an animal. One could leave one's body, have the experience of merging with an archetype, or experience the world of a god or a goddess. The memory of a violent death can be a most traumatic experience.

There can be many different, sometimes never experienced, sensory, energy, and body sensations. These can range from hearing colors to seeing music. It could be an extremely heightened sense of smell, taste, hearing and vision. Some of the most frightening manifestations of the psychedelic experience are energetic. People go through powerful releases, rendering their bodies out of control, shaking, twisting and vibrating. These energies, being activated by the psychedelic substances, could be related to birth, an opening of a frozen body pattern, bioenergetic, neo-Reichian type of release, or be a reconnecting with the universal life force. The life-force is called the kundalini and it manifests in a powerful opening of the body's energy center. It could also be an intensive sexual or other emotional release.

The body sensations also cover a wide range of sensations and feelings. This can be the feeling (for the first time in one's life) of coming home into the body.

Here's a small list of other possible experiences:

- Relieving birth
- Remembering different deaths
- Relieving accidents
- Reliving illness
- Reliving drowning, torture, and many other physical experiences from this and other lives
- Reliving mystical states
- Identifying with and reliving in detail the victimization of humans throughout history.
- Leaving the body and traveling in the spirit realm
- Merging with rocks, animals, plants and experiencing the pollution and death of the planet and different species
- Merging with people, reading their minds, feeling their emotions
- Being caught in a certain experience
- Having a UFO experience
- Being overwhelmed by feelings and emotions

In a psychedelic experience and crisis the person may react to the healer/sitter and project her/his own feelings and experiences onto the healer/sitter. This could be a sexual, demonic, godlike or fearful transference. When this takes place it is important just to be with, not to defend the transference.

3. Working and Being with Psychedelic Emergencies

The experience of the person's crisis is, many times, one of letting go on all levels of one's being. So we have to create a space where it is possible to be open, a space that's quiet, warm, safe, and beautiful. This space is as important as the sitting/facilitating itself. If possible, have flowers, candles, art and writing supplies, blankets, quiet music and soft light.

Pay attention to the body language while you listen to what's being expressed verbally and emotionally. Follow the expression of the person. If they have a lot of energy, let the energy move, let it express itself (we provide a safe space) in whatever form: uncontrolled shaking, yoga postures, dancing, ritualistic type of movements, hyperventilation, kundalini type release.

If the person wants to speak, if sounds come out uncontrolled, support the expression. This might be: a different or dead language, prayers from the different spiritual traditions, far-out stories and memories, jibberish, animal sounds, looping sentences (repeating over and over the same words), lamenting, cries, or screams.

Respond when needed, do not take over, try to (if appropriate) engage in a calm conversation, responding to fear and anxiety.

The most appropriate response to a powerful psychedelic crisis might be to just sit quietly with the person, making them feel safe.

If the person is stuck there are several different ways to respond:

- Wait and calm them down through talk, knowing the duration of the substance taken
- Walk with them, talking or not, until they calm down
- Have them express the experience through sound
- Have them move through it, through a physical expression, holding a certain posture or letting the body go
- One could do some deep, focused bodywork, just hold someone (meeting their needs) or gently massage them. Always ask for permission regarding any kind of physical contact.
- Have appropriate sitter regarding male/female, important when recall of sexual abuse takes place.
- The person could recline, eyes closed or blindfolded, being in a safe place, listening to comforting music and grounding the experience.
- If their emotions are overwhelming them, encourage their expression.

- When the person is calm enough or has come back from their difficult psychedelic experience, have art supplies and writing material available.

Reassure them:

1. This will pass, this is a process.
2. This is an experience other people have had.

There will be support afterwards.

4. Aftercare

There are many ways to integrate the experience and to continue working with the opening that took place. It is important to complete any unfinished gestalt. Further reading should be encouraged, and the person should work with a trained practitioner to complete the experience. This could be:

- Transpersonally-oriented psychotherapy
- Holotropic Breathwork
- Shamanic Integration work
- Different forms of bodywork
- Different forms of energy release work
- Work with archetypes
- Different art forms, making music, dancing, painting, sculpting
- Meditation and other spiritual practices (following the images or insights of the experience)

There are certain medical conditions that should be treated by the medical management. There can be medical pre-existing conditions that are adverse to the taking of psychedelics. Some of the most common are: pregnancy, mental illness, cardiovascular problems like abnormal blood pressure or other heart problems, recent surgeries and/or accidents, and epilepsy.

5. Related Readings

This is a very short list of some of the in-depth work regarding the psychedelic experience and crisis:

1. *Psychedelic Reflections*, Ed. Lester Grinspoon & James B. Bakalar
2. *The Adventure of Self-Discovery*, Stanislav Grof
3. *LSD Psychotherapy*,Stanislav Grof
4. *Spiritual Emergency*, Stanislav and Christina Grof
5. *Green Psychology*, Ralph Metzner
6. *The Unfolding Self*, Ralph Metzner
7. *The Healing Journey*, Claudio Naranjo
8. *The Cosmic Serpent*, Jeremy Narby
9. *The Secret Chief*, Myron Stolaroff
10. *The Ethics of Caring*, Kylea Taylor
11. *Shamanism*, Roger Walsh

Information about Online Edition

This online publication of John W. Allen's book *Mushroom Pioneers* was HTMLed by Erowid and John Allen. Very small edits have been made to the text of the book, but largely the text remains as it was published as a CDROM by John Allen in 2002. The images have been edited for online viewing. Allen expanded the book "Mushroom Pioneers" after its first print publication in 2000. The current version of the book incorporates two other booklets published by John Allen in 1999 and 2000 about R. Gordon Wasson and Maria Sabina, respectively.

The HTML and editing by Erowid was conducted in November and December 2006 with permission of and in collaboration with John Allen. Typos and corrections will be corrected in the document and are invited from visitors. Errors and inaccuracies in the data in the text will need to be reviewed by the author before changes can be made to the document. Please submit any problems with this document to corrections@erowid.org.

Endorsement Blurbs for Mushroom Pioneers

1.) "Use of psilocybian mushrooms constituted the fourth great wave of entheogenic awareness and distribution (after iffy plants like the Daturas, along with marijuana; the wave created by peyote and mescaline; and then that resulting exfoliation of LSD throughout a significant population in the 1960's and beyond).

"These wondrous mushrooms are notable in that they, a) are easily identifiable, b) spring up quite naturally across many segments of both the Old and New Worlds, and c) are gentle in action (in contrast to the 'coercive' nature of other major psychedelics, which tend to emphasize 'ego-death,' for instance).

"Here John W. Allen describes the rather long and strangely convoluted incursion of mind-altering mushrooms via historical vignettes, by snapshots of the principle players, and by the most extensive annotated bibliography of relevant papers and books ... that brings this entire field of knowledge into the 21st century.

"J. W., mycologist extraordinaire, I salute you!"

- Peter Stafford, author of *The Psychedelic Encyclopedia*, *Psychedelic Baby Reaches Puberty* and *Magic Grams*.

2.) "Mushroom Pioneers is a fascinating account of several individuals who were pivotal in the investigation of psychotropic mushrooms and the introduction of these phenomena into Western medicine and science. John W. Allen has documented an important historical development in this book, and provides his readers with a litany of men and women who rescued an ancient tradition from obscurity."

- Stanley Krippner, Ph.D., Professor of Psychology, Saybrook Graduate School; co-editor *Varieties of Anomalous Experience*.

3.) "John W. Allen, the mushroom man, is our celestial tour guide in a school without walls. Rogue scholar, adventurer and gentleman forager, his works surrounding psychedelic mushrooms are 'must reads'. Allen's books are essential and always a treat."

- Thomas Lyttle, editor "*Psychedelic Monographs and Essays*," and "*Psychedelics Reimagined*."

Foreword

by David Tatelman

It is truly an honor to write the foreword to John Allen's book Mushroom Pioneers.

I first met John Allen when he published Magic Mushrooms of the Pacific Northwest in 1976. I was utterly surprised when his book, written by hand, then published and printed by him on an AB Dick Offset Press, did as well as my own slick new book, Magikal Mushroom Handbook. Readers will appreciate his authentic knowledge of the local mushroom scene, not to mention how he personally sold copies, sometimes by leading hunts to his own private spots.

People in the field of mushrooms are very jealous of their turf. Professional mycologists feel superior to amateur mycologists. Those who make little or no money look with disdain at those who have been successful at selling books or products about mushrooms. John Allen has managed to make friends with just about everybody, the icons, the professors, and the amateurs, by proving that he truly loves mushrooms and knows where to find them perhaps better than anybody. Mycologists and authors alike have ended up working with John and acknowledging his authority in the field.

He has found mushrooms directly across from my office, and in places as far away as Thailand, India, Cambodia, Malaysia and Australia. If there is a mushroom to be found, John Allen can find it. He even has discovered a new species which now bares his name, which is more than I can say.

John has been an invaluable historian for the entire mushroom movement. He has self-published a whole library of books about the mushroom world, documenting our humble history.

It is only fitting that John would be the one to write a book about the history of those involved in the movement. I know he doesn't always appreciate being called that, but to me he will always be Mushroom John!

And I mean that as a mark of respect for all he has done for the field of mycology.

Welcome to the Wonderful World of the Sacred Fungi

Introduction

I first became interested in hallucinogenic mushrooms during the early fall of 1972. At that time, the literature on the subject was scant and mostly unavailable to the general public. Those who were aware of the sacred mushrooms did not share their knowledge and even that knowledge was confined to those mushroom species which grew in Mexico and the southeastern gulf states. Only a few knew of their existence outside of Mesoamerica. There was a driving force within me. I could hear the mushrooms calling out my name, and in my own way I called out to them. I needed something new in my life so eventually, out of desperation, I went to the University of Washington's library and inquired about these fungi.

Image 2. King Sphinx
Design by John W. Allen

Reference clerks at the Suzallo library were ignorant of the matter. Simply put, they did not know anything whatsoever about the sacred fungi of Mexico. What was I to do? I next met with Dr. Daniel Stuntz, head of the University of Washington's mycology department. Dr. Stuntz steered me in the right direction by referring me to an article by R. Gordon Wasson which had appeared in the 13 May 1957 issue of Life magazine. This article described Dr. Wasson's research and rediscovery of how the Mazatec Indians in Oaxaca, México, used certain mushrooms in shamanic ceremonies. He also gave me references to Rolf Singer and Alexander H. Smith's pair of articles in Mycologia vol. 50, which told of the traditional Mesoamérican use of the sacred mushrooms and also provided a key to several species of entheogenic mushrooms which were common in the Pacific Northwestern United States. These articles in turn led me to a pioneering ethnobotanical paper written by Richard Evans Schultes in the late 1930s.

This piqued my interest inordinately, hence I proceeded to look up several of these rare articles. However, when I began my research I found that several of the articles to which I had been referred by the late Dr. Stuntz were either missing from the bound library copies of the journals or had at least had the photographs of the mushrooms excised. Even the 1957 Life magazine article by R. Gordon Wasson was missing pictures from the copy which I found on the shelves at the University of Washington's library. Eventually I was able to purchase a copy from a used bookstore, which led me in time to find other publications about the mushrooms. Thus began my quest and life-long-study of the sacred fungi.

In the fall of 1977, I was most fortunate to attend the 2nd International Conference on Hallucinogenic Mushrooms at Ft. Worden near Port Townsend, Washington. It was at this conference that began my symbiotic relationship with these mushrooms. This new field of endeavor opened up many new avenues of research into subjects in which I had henceforth not shown the slightest interest.

As my knowledge began to grow, my studies came to encompass various and sundry fields spaced shelves apart or interspersed at intervals between shelves, in separate buildings, and even in numerous libraries. I digested every thing I could read related to the various fields tangential to the study of sacred fungi.

This also was the beginning of my relationship with the many scholars who had brought to the world's attention the existence of the mushrooms. Eventually, I would come to call some of these intrepid psilophores my friends. Among this first wave I include: Richard Evans Schultes (the greatest ethnobotanist of this century), R. Gordon Wasson (the founder of ethnomycology), Albert Hofmann (the discoverer of LSD), Andrew Weil (who first reported on the ludible use of psychoactive mushrooms), mycologists Gastón Guzmán (the Mexican authority on the taxonomy of these hallucinogenic mushrooms), Rolf Singer, Alexander H. Smith, Roy Watling, and others. This first wave might include the late Timothy Leary, György Miklos-Ola'h, and the late French mycologist Roger Heim.

The second wave consisted of a younger generation which emerged from the psychedelic sixties and included ethnopharmacognost Jonathan Ott, mushroom-cultivator Paul Stamets, mycophiles such as Gary Lincoff, Steven H. Pollock, Gary Menser, Bob Harris, Peter Stafford and publisher David Tatelman of Homestead Book Company (distributor of mushroom books and growing kits).

The third wave consists of the same generation who somewhat later embarked on this path, and includes such prominent researches as Jochen Gartz, Giorgio Samorini, Antonio Bianchi, Francesco Festi, Tjakko Stijve, Mark D. Merlin, Christian Rätsch, Roger Liggenstorfer, Dennis and Terence McKenna, Arno Adelaars, Karl L. R. Jansen, Hans van den Hurk, and others too numerous to mention (the many chemists, psychologists, shamanic healers, philosophers and poets). Last but not least, in the fullness of time, I now include myself in this third wave.

The Spanish, The Aztecs and the Sacred Fungi

Psychoactive fungi of the genera Psilocybe and possibly Panaeolus have been traditionally used for over 3000 years. The use of these interesting fungi in magico-religious ceremonies as divinatory sacraments among several tribes belonging to the Nahua speaking Indians of Mesoamerica is well documented (Wasson & Wasson, 1957 [186]; Schultes, 1939 [103], 1940 [104]).

These Nahua-speakers were the ancestors of the once mighty Olmecs, Toltecs, and Aztecs. Additionally, the Mayan cultures of Central America may also have employed the mushroom entheogens ceremoniously. The indigenous native inhabitants of Mesoamerica currently employ several entheogenic mushrooms for the purpose of healing and curing through divination via magico-religious veladas.

Jim Jacobs, a renowned investigator of the sacred Mexican "magic mushrooms" claims that "their use in a magico-religious ceremony is correct, but that their use is much broader" then one could possibly imagine.

We would know little or nothing of these indigenous peoples' use of the mushrooms, were it not for Doña María Sabina, a Mazatec curandera who shared her secrets with R. Gordon Wasson and photographer Alan Richardson and made it possible for all of us to experience her ecstatic and sacred knowledge. What led to these discoveries will now be presented below.

Many of the early Spanish chroniclers (which included naturalists, botanists and members of the clergy) sailed from far across the Atlantic. They may or may not have been the first to explore this brave new world of ours, but they are the first to have recorded the history of their discoveries. They traveled here under the fear of God, leaving behind them the terrors of the dark middle ages, and leaving behind them a world they were just learning to crawl out from under.

More than 500 years have passed since España triumphed over 700 years of Moorish rule. In 1469, 17-year-old Ferdinand V, ruler of the kingdom of Aragon met and married 18 year-old Isabella I, queen of Castile and Leon. This was an important step in making España a single kingdom. They had fought the Moors, the Mohammedan invaders who had ruled much of España for seven hundred years. In 1492, after more than twenty years of fighting, Ferdinand and Isabella conquered the city of Granada, the last Moorish stronghold in what is now Spain (Nat. Geo. Mag.)[81]. It was also, at this point in their history, that Spain began to expel most Jews from their country, forcing several hundred thousand Jews to migrate to other countries, except for those who converted to Christianity.

Goddess of Shrooms

After the war with the Moors was over, Ferdinand and Isabella gave court to a navigator, who was also a map-maker as well, a man who claimed to know the "secrets of the winds." This man was Christopher Columbus, who had dreamed of sailing west for more than twenty years. At first, Columbus tried to get help from the King of Portugal, but failed. Then in 1485 he turned to King Ferdinand and Queen Isabella, who at that time were fighting to drive out the Moors from their country, so Columbus had to wait.

Finally his orders arrived, given to him by Ferdinand and Isabella: the royal degree directing him for his first voyage. These documents claimed that Columbus would be sailing to "certain islands in the sea" which he knew existed. Interestingly, Columbus had once sailed to Scandinavia and may have even heard stories about the travels of Leif Ericsson, thus presenting him with an incentive for finding shorter sailing routes to the Indies.

After the war between the Moors and Spain was over, it appeared that it was very important for the merchants of Spain to find a new route to India and Asia (Nat. Geo. Mag.)[81].

After their defeat in Grenada, the Mohammedan Arabs had shut off all of the eastward land routes to Asia. Portugal's explorers had not yet completed their passage around Africa, so new sailing routes were often discussed by the merchants yet no one was enthusiastic about attempting to find newer sailing routes to increase the trade of the country.

The purpose of Columbus' voyage and subsequent ventures across the Atlantic was to increase the resources of Spain with new avenues of commerce and trade. Eventually, they accidentally stumbled upon this brave new world, landing first at what is now San Salvador and later setting up the first colony in Haiti. Eventually Columbus explored most of the South American Coast, and Central America as far west as Panama.

In 1519, the Spanish conqueror Hernando Cortez landed with his men in Mexico and set up a new town, Vera Cruz, and then marched toward the capital city. Within two years Cortez had conquered the country (Nat. Geo. Mag.)[81]. Cortez also began the task of ordering his clergy to convert the Indians into Christians and stopped them from worshipping demonic idols and from performing their rituals which sacrificed human beings to the gods. While these human sacrifices must have seemed very cruel to the invading Europeans, it would be more reasonable to assume that Cortez turned out to be more cruel in his conquest of the native peoples and the way he conducted his conquest than what he was trying to destroy or change. Not only did Cortez destroy many of the Aztec temples but he also brutally put down all resistance. At the time of the conquest it was believed that there were more than 100,000 Aztecs who lived in the capital and over six million Indians living throughout Mexico.

Imagine the fear, which the native population held towards their conquerors. Here was an enemy who had greater powers than their mighty Gods. Weapons of mass destruction, more powerful than their spears and arrows. Muskets, rifles, cannons. Armored suits, mighty vessels which breached the sanctity of their waters.

Once the conquest had begun the invaders immediately began to build their churches, the base core of their spiritual imaginations. The many treasures they collected and cataloged were sent back to their homeland. They carried these precious cargoes to Spain in the name of God and King. Interestingly, many treasure vessels sank after their embarkation mainly because their precious vessels were too heavily laden with treasure. Ironically it was surely their greed which caused their ships to sink (remember that these were seasoned seamen. They were definitely good at their skills and they knew how to sail their ships). Furthermore the Spanish invaders were also seeking such treasures as the Coronado's "Seven Cities of Cibola" (the lost city of gold or "El Dorado" as it later became known), the "fountain of youth" and even aphrodisiacs to seduce young women.

During this period of conquest, they proceeded to rape the land of its many resources and strip away the native peoples of their culture, heritage and religion. Soon they thus began their indoctrination of their way of life into that of the native population. This was achieved largely through the fear of death; thus the conquerors began to civilize the heathens and converted many Aztecs to Christianity.

An interesting observation which has not before been under discussion is about one of the rewards given to all Indians who converted to Christianity. This meant that if any Indian was attacked, beaten on or in danger, it was the honored duty of the soldier or conquistador, all loyal to the King of Spain, to defend, with his life, any Indian who was of the same faith. We must not forget that the Moors were repelled and expelled from España; so that the Catholic church could exist. In fact, one of the titles of Ferdinand, King of España, was "Protector of the Faith" or "Keeper of the Faith," Thus the reason for the soldier to defend a Christian Indians life.

In contrast to this above noted observation, in the American colonies the English missionary breakaway Protestant laymen imposed their harsh religions doctrines and dogma on the native populations whom they encountered and were able to convert only small populations of the native inhabitants into their religions. However, English and European attitudes towards people of a different skin color were obvious (India is an example) and the Indians who became christianized were probably not even allowed to sit at the same table with their white brothers even though they were of the same faith.

Eventually, the conquerors had succeeded in their endeavor to devour the land they now lay claim to. Now the botanists and clergy began to initiate the long and somewhat tedious task of cataloging and recording on paper all that they had discovered in the new world.

During the initial conquest of Nueva España from the Caribbean throughout Central America to México, the use of inebriating intoxicants (including fungi) was a dominating factor in the culture and peoples of the Aztec empire. These sacraments were frowned upon by the Spanish invaders, who observed the Aztec priests and their followers being served the sacred fungi at festivals and coronations. It should be pointed out that the Spanish were very mycophobic and they were repulsed by the mere mention of any type of mushroom. They also deplored the pagan like rituals and the priests who employed mushrooms and other magical herb/drug plants as divinatory substances. They wrote in their histories that teonanácatl (Teunamacatlth), a term used by the Nahuatl speaking Aztec priests in describing the sacred mushrooms may have implied "God's Flesh or Flesh of the Gods." However, many historians wrote of the mushrooms in a negative view. For example: one author described the mushrooms as "Hongol demonico ydolo" (for more terms and names of the sacred mushrooms, see Allen, 1997c [5]). According to Wasson (1980 [174]), "teo" meant awesome or wondrous and "nanacatl" implied mushroom or even meat.

Teonanácatl or "magic mushroom" was one of the most important of the many narcotic drug/herb plants described in several codices written after the arrival of the Spanish in the 15th century. The mushrooms were often administered among the common people, merchants, visiting dignitaries; and even the wealthy were known to have consumed them.

Other plants were also employed in the treatment of different ailments, divination's and for healing or curing and were also used during different seasons. Additionally, several other minor plants were also employed when the more popular remedies were not available.

Many plants used in these magico religious ceremonies more than 400 years ago by the Aztecs and as much as 2000 years earlier by their ancestors the Olmecs and Toltecs, and quite possibly the Mayan people, are still in use today. These include peyote (mescaline), *ololiuhqui-tlitlitzin* (morning glory seeds = ergine alkaloids), *Salvia divinorum* ("Leaves of the Shepherdess" a member of the mint family), *Datura* (jimsom weed, also known as torna loca, toloache or tolatzin), mescal beans (cytisine), puffballs (*Lycoperdon mixtecorum*) or (*Lycoperdon marginatum*). The former is referred to as "*gi-i-wa*" and means "fungus of the first quality" and the latter implies "fungus of the second quality." It has been reported that they cause auditory hallucinations. Use of these alleged puffball inebrients occurs primarily among the Mixtec shamans.

Second only to peyote are the sacred mushrooms referred to by the Aztecs as *teonanácatl*. The majority of the sacred mushrooms of Mesoamerica belong to the genus *Psilocybe*, and a few quite possibly belong to the genera *Panaeolus* and *Conocybe*.

Although indigenous use of many psychotropic plants in Mesoamerica is not uncommon today, the ritualistic or ceremonial use of the sacred mushrooms and other drug/herb plants can be traced back to approximately 1000 BC.

The numerous descriptions recorded by the clergy and historians concerning the effects of these drug/herb plants and their uses among the Aztec people are molded in fear and plastered in bigotry and false heresy. The effects of the mushrooms on those who had experienced them were often reported in a negative vein, most probably by the botanists and historians who were eager to appease their masters back in Spain. The Spanish historians often described the effects of these plants on native peoples as leaving their users in uncontrollable fits, claiming that the native people would even commit violent acts towards themselves and each other. Many would fall into rages as if in a stupor. These descriptions could very well describe an alcoholic syndrome in contemporary society.

The Spanish persecuted, often murderously, those who did not adhere to the catholic ways. It was because of this persecution which caused the native population to hide the use of these mushrooms from their Spanish peers. Thus word of the sacred remained a secret to most of the west until R. Gordon Wasson found the Oaxacan Shamaness María Sabina and wrote of his rediscovery regarding the existence of these mushrooms which are still considered sacred by indigenous peoples living in Certain regions of Mesoamerica (Wasson, 1957 [140]; Wasson and Wasson, 1958 [187]; see also Allen, 1997a [3], 1997b [4]). The legend of that discovery is now retold here one more time so that all may learn the tale and tell it to others.

This volume of *Ethnomycological Journals Sacred Mushroom Studies* Volume VII presents an overview of R. Gordon Wasson's discoveries, four short biographies of the original pioneers who divulged the mysteries of the mushrooms, and their interrelationship with some of the many collaborators who forged new trails in these uncharted domains, presenting new insights into humankind's relationship with sacred mushrooms of the gods. Furthermore, there are many short biographies devoted to many of those brave psilophores who helped paved the way to the magical world of the wondrous mushrooms. Although the present study lists works devoted to psilocybian mushrooms, many of their authors are also prominent researchers and investigators of other kinds of visionary or psychoptic organisias. I have also included in this volume, revised versions of both volume I and II of my series *Ethnomycologial Journals Sacred Mushroom Studies*, *María Sabina: Saint Mother of the Sacred Mushrooms*, and *Wasson's First Voyage: the Rediscovery of Entheogenic Mushrooms*.

As noted in Volume IV of this series, the fear of persecution on the part of the Spanish conquistadores among those who used the sacred mushrooms and other entheogens for healing ceremonies became widespread throughout Mesoamérica. Naturally, the shamans who hid from the Spanish the special powers they derived from the sacred mushrooms concealed this use from public scrutiny, a situation which continues today in the form of (underground) psychedelic therapy in the United States and Europe.

Chapter 1. Modern Field Research on Teonanácatl 1915-1940

Today in México, only a handful of remote montane tribes still practice the customs and rituals of what once must have been a splendid and powerful system of worship and empirical magic. So utterly complete was the neglect and ignorance in our western world of the ethnobiological aspects of Aztec and other Mexican shamanism, that in 1915, William E. Safford, a reputable and distinguished USA botanist who was than a sort of expert on the subject of many Native American psychotropic plants, claimed that the visionary mushrooms as described in the Spanish histories did not in fact exist and that the Mesoamérican Indians had never used such, whether before, during, or after the conquest. Disdaining the graphic testimony of several Spanish chroniclers, Safford dismissed the well-documented evidence of the chroniclers, mostly clerics, who described as mushroomic, the effects the mushrooms allegedly had upon those who consumed them. There is no evidence any of the Spaniards deigned to sample the psychoptic mushrooms.

> **"[T]hree centuries have failed to reveal that an endemic fungus is being used as an intoxicant in Mexico. Nor is such a fungus mentioned either in works on mycology or pharmacology, yet the belief prevails even now that there is a narcotic Mexican fungus."**
>
> W.E. Safford, 1915 in "An Aztec Narcotic", erroneously stating that *teonanácatl* was actually peyote.

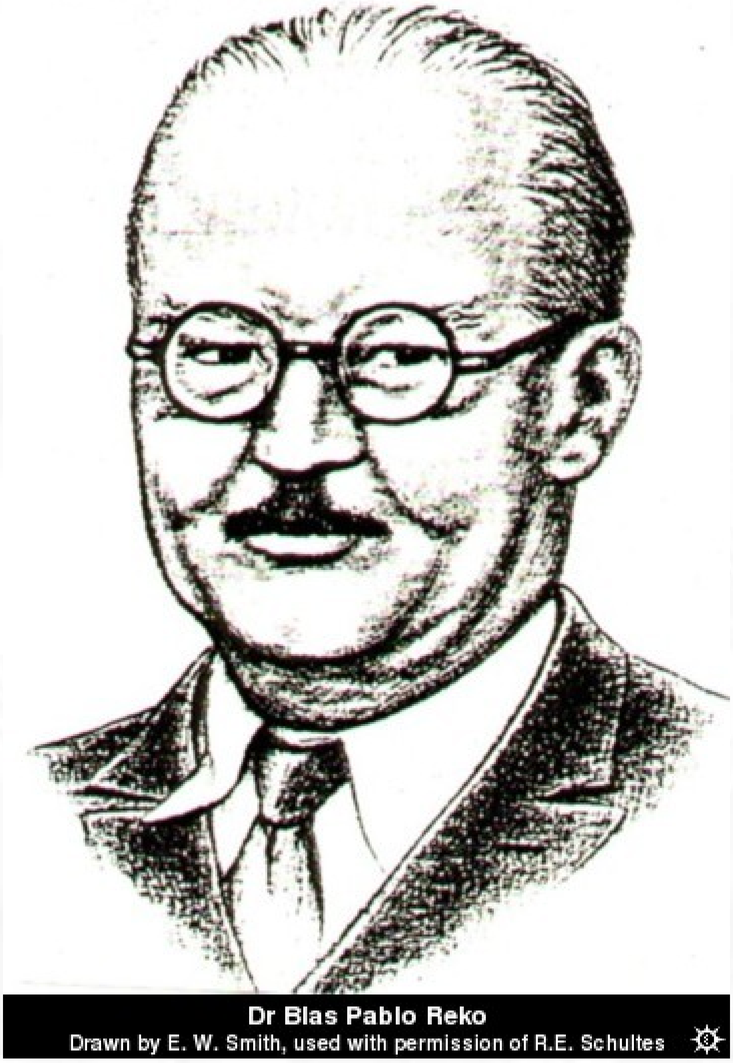
Safford (1915)[99] presented a botanical society the results of his study of an Aztec sacred inebriant referred to in a few historical sources as *teonanácatl* which means "wondrous mushroom." He claimed that the so-called wondrous mushrooms were in fact dried peyote buttons and that no mushrooms had been used as inebrients by the native peoples of Mesoamérica. Safford's colleagues displayed little interest when he claimed that the word teonanácatl simply meant peyote. In his paper, he reproduced a photograph of dried peyote buttons. These could easily have been mistaken for dried mushroom-caps, which is what they vaguely resembled to the untrained eye. Safford relied on the fact that "three centuries have failed to reveal that an endemic fungus is being used as an intoxicant in Mexico. Nor is such a fungus mentioned either in works on mycology or pharmacology, yet the belief prevails even now that there is a narcotic Mexican fungus."

According to Safford, the early Spanish descriptions of numerous medicinal plants from Mesoamérica led him to believe that the Aztec entheogen ololiuhqui was either the seed of *Datura* or of a morning-glory species, but he further denied that either plant provoked visionary effects (for a more detailed description of the properties of the sacred morning glory seeds, see Albert Hofmann's biography, "*LSD: My Problem Child*" [1980][38]).

As late as 1921, Safford still held firm to his theory by again denying the existence of the sacred mushrooms, claiming that they were simply dried peyote buttons. Safford (1923)[100] also noted: "Peyote has been called a habit-forming drug, and some writers have likened it to hashish, or Indian Hemp, the latter which had been introduced into the country of México and our southwest under the name of Marijuana, is a most dangerous drug. Introduced clandestinely into prisons, it has of course, been the cause of riots. Its use is now forbidden in México by the government."

It should be obvious to anyone who reads the above letter by Safford that he was a confirmed pharmacophilac and thanks to his prominence the mushrooms continued to be obscured from the world until the late 1930's when they were once again brought to the attention of the scientific community.

In the second decade of this century, Austrian Blas Pablo Reko(1919)[93], a physician with an interest in ethnobotany, learned that some groups of Indians living in the Mexican state of Oaxaca were still using psychoptic mushrooms in secret ceremonies perhaps involving ancient rites. These rites were performed apparently for the purpose of divinatory healing. Reko published his findings in a journal entitled *El México Antiguo*.



Dr Blas Pablo Reko
Drawn by E. W. Smith, used with permission of R.E. Schultes

Fig. 1. Dr. Blas Pablo Reko
Drawn by E.W. Smith

Reko subsequently discussed this discovery with his colleagues, who paid little attention to his mushroomic theories and showed no interest in pursuing this information on the supposititious use of inebriating mushrooms by the Indians of Mesoamérica. Reko wrote that *teonanácatl* was "Div. géneros de hongos, especialmente un hongo negro que crece sobre estiércol y produce efectos narcóticos." ["Various genera of mushrooms, especially a black mushroom that grows on dung and produces psychotropic effects"].

Reko (1923)[94] later wrote to Dr. J. N. Rose of the United States National Herbarium that "I see in your description of *Lophorphora* (peyote) that Dr. Safford believes this plant to be the '*teonanácatl*' of Sahagún which is surely wrong. It is actually as Sahagún states, a fungus which grows on dung heaps and which is still used under the same old name by the Indians of the Sierra Juarez in Oaxaca in their religious feasts." Safford's last defender, Huntington Cairns (1929)[9], became the last person to expound the Safford theory.

B. P. Reko's cousin, Victor A. Reko (1928)[95], published the first objection to Safford's claims. It appeared in a book written years later in 1936. Below is an excerpt describing the effects of the mushrooms taken from that book entitled *Magische Gifte: Rausche und Betäubungsmittel der Neuen Welt* ("*Magical Poisons: inebrients and Narcotics of the New World*"):

> "The *nanacates* are poisonous mushrooms which have nothing to do with peyote. It is known from olden times that their use induces intoxication, states of ecstasy and mental aberrations, but, notwithstanding the dangers attendant upon their use, people everywhere they grow take advantage of their intoxicating properties up to the present time."

In 1936, an Austrian engineer, Roberto J. Weitlaner, who was also an avid ethnobotanist, spent four days in Huautla de Jiménez, Oaxaca, where he was engaged in linguistic investigations. Weitlaner had learned of the existence of the sacred mushrooms from a Mazatec merchant named José Dorantes. Dorantes had described to Weitlaner his reactions after eating three of the mushrooms which were given to him during a divinatory healing (Johnson, 1940)[46]. It was Weitlaner who first realized that these sacred mushrooms were most likely the teonanácatl described in the chronicles of the Spanish clerics. During this period, several mushroom specimens were collected and forwarded to Blas Pablo Reko. Reko in turn sent the specimens to Harvard University for botanical identification. However, the specimens spoiled before they arrived, thus further delaying their identification and proof of their existence to the scientific community.

In 1936, Weitlaner became the first white man in modern times to observe an actual sacred mushroom ceremony. Two years later, in 1938, his daughter Irmgard, her fiancé Jean Basset Johnson and two friends (Louise Lacaud and Bernard Bevan) continued the investigations begun by Weitlaner. These intrepid investigators were not only able to gather a considerable amount of data on Mazatec shamanism and the use of the sacred mushrooms, but in the process became the first westerners to witness a Mesoamérica shamanic mushroom ceremony. The velada was held in a hut in the tiny montane village of Huautla de Jiménez. Johnson (1939a)[46] published two startling papers regarding his observations on Mazatec "witchcraft." Furthermore, while in Oaxaca, these investigators met Dr. Richard Evans Schultes and Dr. Blas Pablo Reko who were also in Huautla collecting ethnomycological data and mushroom specimens.

While Johnson referred to these ceremonies as examples of "witchcraft", it should be noted that ethnobotanist William Emboden (1979)[16] mentioned that certain modern-day "witches" use a species of Panaeolus mushroom as one of many inebrients in their rituals. Emboden said that the fungus used by a cult of contemporary witches living in Portugal was identified by Roger Heim as *Panaeolus papilionaceus* which may or may not be a synonym for *Panaeolus subbalteatus* or possibly *Copelandia cyanescens*.

Chapter 2. Richard Evans Schultes

The collecting of teonanácatl mushrooms took place when a young Harvard botanist, Richard Evans Schultes, made a trip to Huautla de Jiménez with Blas Pablo Reko (Schultes, Pers. Comm. 1989)[109] and collected several specimens of mushrooms which were suspected of being used in "magico-religious ceremonies." After sun-drying several specimens of these mushrooms, they mailed these samples to Harvard University for identification.

Mushrooms collected by Schultes (1939 [103], 1940 [104], 1978 [106]) and Schultes and Reko, were later identified as*Stropharia cubensis* Earle, *Psilocybe caerulescens* Heim and some specimens of *Psilocybe mexicana* Heim which were mixed and confused by the presence of another mushroom identified as *Panaeolus campanulatus* var. *sphinctrinus*. After these mushrooms were deposited in the herbarium at Harvard, confusion surrounded their botanical identification and their equivalence with the sacred mushroom of the Aztecs until the early 1950's (these discoveries will be discussed in Chapter Three).

Richard Evans Schultes is a most remarkable man. He is one of the pioneers involved in identification of New World shamanic plants, especially those from Mesoamérica and the Amazonia of Colombia in South America. His research into psychoptic plants is undoubtedly the most extensive ever undertaken by any botanical scientist.

RE Schultes, J Ott (Port Townsend, WA, 1977)
Used with permission of Gastón Guzmán

Richard Evans Schultes (1977)

Richard Evans Schultes, Jeffrey Professor of Biology and Director of the Botanical Museum of Harvard University (Emeritus), is a native Bostonian. Not merely a botanical explorer, he is a noted ethnobotanist and conservationist. Among his numerous awards are the Cross of Boyacá, Colombia's highest honor, and the annual Gold Medal of the World Wildlife Fund, presented by H.R.H. the Duke of Edinburgh; in 1987, he received the prestigious Tyler Prize for Environmental Achievement.

His crowning achievement however, was the receipt of botany's Nobel Prize - the Gold Medal of the Linnean Society at London in 1992. Schultes is also on the exclusive list of 50 "Foreign Members" of that in itself exclusive society.

His explorations and botanical identification of thousands of plants from Amazonia is as immense as it is eclectic. During his fourteen years in the Amazon, Schultes had collected more than 24,000 plants new to science of which over 80 are entheogenic (Davis, 1996)[12]. He has also written more than two dozen books and over 100 scientific articles on his discoveries. He is, moreover the only living ethnobotanist to have more than two million acres of land named in his honor; Sector Schultes, part of an Amazonian ecological preserve formally designated in 1986 by the Colombian government.

The field of ethnobotany was Schultes' framework throughout his life. His field work in Oaxaca, México in 1938 and 1939 was somewhat limited due to the Second World War. However, he made history by pioneering the study of shamanic mushrooms of the Mazatec Indians.

Richard Evans Schultes was born in Boston, Massachusetts on January 12, 1915. When he was about six years old, Schultes developed an illness which caused him severe stomach problems. During this period, his father and mother would read to him and one book which caught Schultes' attention was Richard Spruce's "Notes of a Botanist on the Amazon and Andes." This was young Schultes' introduction to the world of botany.

As a young child, Richard once read a floral guide given to him by an uncle and after studying it, would collect leaves to identify and press. It seems that this helped the young collector develop what some people refer to as "the taxonomic eye."

In 1936, Schultes was just another premedical undergraduate student at Harvard University and one of his classes was Biology 104. While attending a course on "Plants and Human Affairs", Schultes was assigned to read a book by Heinrich Klüver[48] entitled "*Mescal: The Divine Plant and its Psychological Effects*." Unbeknownst to Schultes, this assignment was destined to change the course of his entire life.

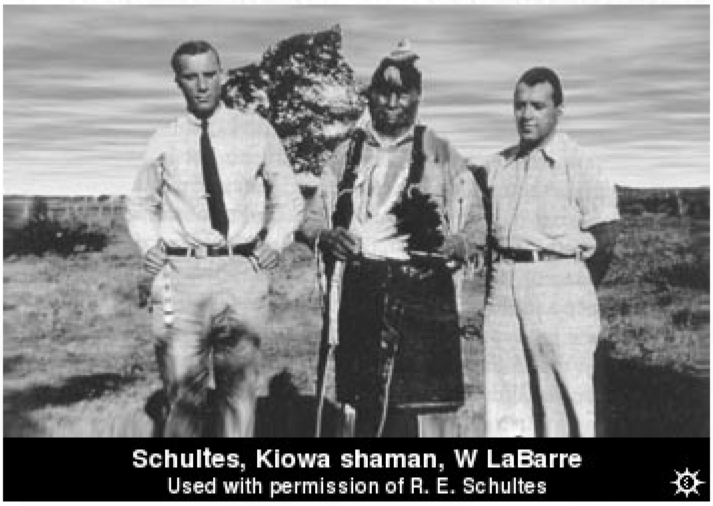
Previously unaware of peyote, Schultes soon began to develop a burning desire to experience mescaline firsthand. Schultes met with his professor, Oake Ames, and soon found himself with funding (most of which came directly from the pocket of his mentor Ames). Eventually Schultes met Weston LaBarre, a young student from Duke University in North Carolina who also shared an interest in peyote (LaBarre went on to become an anthropology professor and the author of *The Peyote Cult*, the definitive book on the peyote religion and *The Ghost Dance: The Origins of Religion*).

Together, Schultes and LaBarre traveled to Oklahoma where both participated in a Native American Church peyote-ceremony with the Kiowa Indians. There Schultes consumed the sacred cactus on which he then wrote his senior honors thesis.

Schultes soon decided that economic botany was the study he would pursue, so he completed his graduate work on the medicinal plants of Oaxaca, México. Schultes interest in Oaxacan plants came from having read some of the selected writings of the 16th and 17th century Spanish friars and historians who mentioned the existence of innumerable medicinal plants, some of a psychoactive nature, including the morning-glory seeds known as *ololiuhqui*.

Not only did Schultes help rediscover the modern use of the ololiuhqui seeds among the Mazatec Indians, but along with Blas Pablo Reko also collected specimens of the putative sacred mushrooms known as *teonanácatl* - of which Safford had only just denied the existence (Schultes, Pers. Comm. 1989)[109].

As noted previously, the first mushrooms collected by Schultes and Reko fit the botanical description of *Panaeolus campanulatus* var. *sphinctrinus*. In his 1939 and 1940 papers on the identification of the visionary Nahua mushroom, Schultes alleged that the mushrooms mentioned by the Spanish chroniclers probably belonged to the genus Panaeolus. It was important for these scientists to collect and identify the species they believed were the Aztec *teonanácatl*, yet they couldn't find anyone to perform for them a shamanic mushroom ceremony such as they suspected continued being held in secret. According to Schultes (1969)[105], "so few mushrooms were gathered, because of the unusually dry season, that it was not possible for me to ingest them experimentally; all were needed as voucher herbarium specimens."



Schultes, Kiowa shaman, W LaBarre
Used with permission of R. E. Schultes

Fig. 2. Richard Evans Schultes, a Kiowa shaman, and Weston LaBarre

Another mushroom Schultes collected among the Sierra Mazateca was known by the Mazatec Indians as kee-sho. This mushroom at the time was incorrectly identified by Rolf Singer as*Stropharia cubensis* Earle. Schultes later collected specimens of *Stropharia cubensis* from dung after heavy rainfalls.

It was later determined that Schultes' identification of the mushroom known as kee-sho actually fit the taxonomic description of *Psilocybe caerulescens* var. *mazatecorum* Heim, a mushroom employed by Mazatec shamans in religious healing ceremonies. However, Schultes did collect *Stropharia cubensis* in Oaxaca in the late 1930's, but could not find any reference to its use prior to the conquest. It is not known if this species occurred in the new world until after the Spanish brought cattle onto the continent, most probably from India, the Philippines or possibly from Africa - although this species does occur in the manure of other ruminants. It is also probable that *Stropharia cubensis* was not one of the mushrooms being used by Aztec shamans and referred to as *teonanácatl*. Singer later amended this species to *Psilocybe cubensis* (Earle) Singer. Schultes (1978)[106] later wrote: "subsequent studies by R. Gordon Wasson, R. Singer, R. Heim and Gastón Guzmán, have indicated that *Stropharia* (*Psilocybe*) *cubensis* Earle is one of the more important sacred Mexican mushrooms" in use today.

In Palenque, México, it is referred to as San Isidro Labrador (St. Isidore the Plowman), so aptly named for a patron saint of agriculture of old México. Even though it is common in most regions throughout Southern México and Central America, there are many shamans who consider it inferior to other varieties and many do not use it professionally except when other species are not available. One possible reason it may be avoided is that it grows in manure; more likely this is simply because it is not pre-Colombian and associated with the offal of the conquistadores cattle.

Schultes then presented to the scientific community numerous references to the use of inebriating mushrooms by Mesoamérican shamans and others. Schultes reported in his 1939 and 1940 papers that several codices not only had described the existence of the sacred mushrooms, but had also vividly described observed effects on people who had consumed the mushrooms, thereby verifying their (the mushrooms) existence and use. Thus Schultes paved the way, so to speak, for the Wassons and others eventually to follow his footsteps, when he published these findings (Schultes, 1939 [103], 1940 [104], see also, Schultes, 1987 [107]).

Schultes' research and oftentimes tedious hard work into the realm of the shamanic mushrooms soon drew to a close as other events directed him to the heart of the vast Amazonian forest to study dart poisons and rubber. As the war years dragged on, the sacred mushrooms of México once again fell back into the shadows of oblivion. Nevertheless, Schultes' doctoral thesis on the medicinal plants of Oaxaca and his two published papers on teonanácatl (Schultes, 1939 [103], 1940 [104]), eventually found their way into the hands of an interested reader, R. Gordon Wasson, a fifty-four-year old Banker with Morgan Guaranty Trust. Wasson, along with his wife Valentina Pavlovna Wasson was able to accomplish that which Schultes had been unable to ingest the shamanic mushrooms of the Mazatecs (see Allen, 1987 [2], 1997a [3]).

Chapter 3. Rolf Singer and the Misidentification of Teonanácatl

Both Schultes' and Schultes & Reko's original 1938 collections of Oaxacan fungi were forwarded from México to the Farlow Herbarium at Harvard University. They represented probably three different species (*Panaeolus campanulatus* var. *sphinctrinus*, *Psilocybe cubensis* identified by Singer and *Psilocybe caerulescens* by recorded name). These collections were accidentally placed on a single herbarium sheet and were later separated in 1941 by mycologist Rolf Singer. In 1958, mycologists Rolf Singer and Alexander H. Smith conducted follow-up research on the previous studies by Schultes and Reko, Wasson and Heim. Singer (1958)[116], used Heim's papers and illustrations from Wasson's Life article as a guide list and) described the labels for both collections of Schultes and Reko's fungi collections but was confused by Schultes' written description of a species that Singer believed was *Panaeolus sphinctrinus*. Interestingly enough, Schultes' macroscopic description of this species actually fit the description of *Psilocybe mexicana* Heim. The first label on this herbarium sheet read as follows:

> "Springy meadows in rainy season. Huautla, July 27, 1938. Stem: 1-2 mm. diam: 10 cm. high; hemispherical but often cuspidate; gills dark brown-black, whole plant coffee brown, black when dry. Mexican name is she-to; tso-ska. Said to be poisonous in overdose of 50-60 mushrooms, but in moderate quantity it produces hilarity and general narcotic feeling of well being for an hour. Excess doses said to produce permanent insanity."

RE Schultes in his office
Unknown photographer, used with permission of R. E. Schultes

Fig. 3. Schultes in his office Harvard, late 1980's.

It appears that Schultes may have collected two different species of mushrooms in the springy meadows. One variety being *Panaeolus campanulatus* var. *sphinctrinus*and the other being *Psilocybe mexicana*. Singer

(1958)[116] had noted that "Springy meadows was the known habitat for *Psilocybe mexicana* and cuspidate is a characteristic feature of the genus *Psilocybe*, as are the brown gills which were mentioned and the coffee brown color of the mushroom." However, the black gills reported by Schultes would definitely fit the description of a *Panaeolus* species. Schultes had not reported that his collection occurred in manure or from the ground. If they were coprophilous Schultes would have mentioned it. Furthermore, she-to and to-ska are epithets used by the Mazatec and Chinantec to describe *Psilocybe mexicana* (see Allen, 1997b)[4]. The author also found the epithets to-shka and shi-to being used to identify a species of *Panaeolus*.

The second collection deposited by Schultes and Reko had originally been misidentified by Singer as *Stropharia* (*Psilocybe*) *caerulescens*. The paper on this second sheet read as follows:

> "Plantae Utiles Mexicana, Oaxaca. Common Name (Mexican) nanacate. Tribe: Mazatec. Indian name: kee-sho. Habitat freshets during the rainy season. Locality: Huautla. Uses: from four to eight are eaten to produce a temporary narcotic state of hilarity. Said to be poisonous if taken in excess, causing permanent insanity" (Singer & Smith, 1958)[116].

Singer mistakenly noted these mushrooms to be *Stropharia caerulescens* [syn.=*Psilocybe cubensis* (Earle) Singer]. Later Singer realized that he had misidentified this species when he learned that the word kee-sho referred to the Mazatec Indian landslide mushroom later identified as *Psilocybe caerulescens* var. *mazatecorum*. Ott (1993)[85], in a personal communication to the author, believed these mushrooms to be *Psilocybe caerulescens* Murr., a mushroom known to occur in sugar cane mulch and at roadside landslides, yet the habitat for this collection was listed as freshets, which as one may surmise, are the dung of cattle. Thus it appears that this second collection was probably *Psilocybe cubensis* (Earle) Singer. Interestingly, in 1923, *Psilocybe caerulescens* Murr. was originally discovered and identified in Huntsville, Alabama, yet it has never been reported from Alabama since. However, this species has since been reported from Florida (Jacobs, 1975)[44].

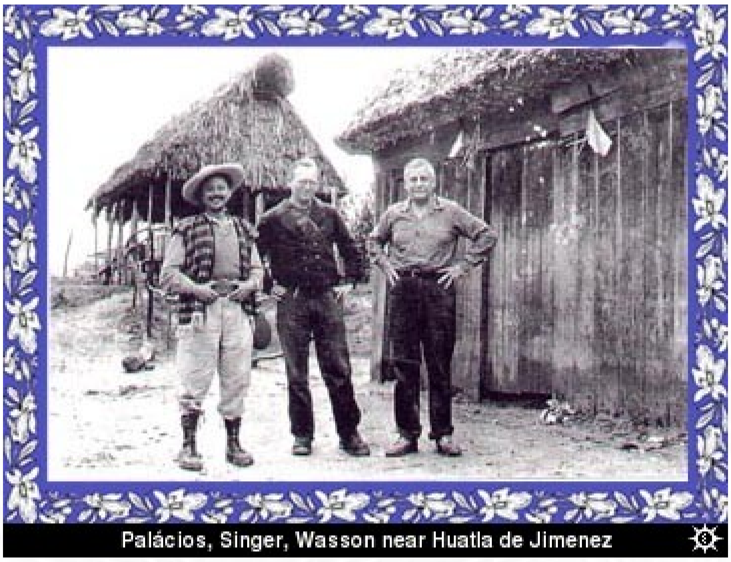
Singer (1958)[116] noted that Santesson (1939)[102], was probably the first author to publish data on both pharmacological research and chemical analyses of fungi believed to be the cause of what is known as cerebral mycetismus or psychotropic mushroom poison.

Santesson conducted laboratory experiments with extracts of various mushrooms using animal subjects in his investigations. However, it should be noted that it was actually Dr. Michael Levine who in 1917 attempted to investigate the suspected effects of *Panaeolus venenosus* (=syn. *Panaeolus subbalteatus*), a fungus known to cause cerebral mycetismus in humans, yet Dr. Levine did not attempt to isolate the suspected ingredients of the mushrooms during his course of research.

One of the mushrooms allegedly used in Santesson's experiments was *Armellariella mellea* (the honey mushroom). Singer wrote that he was in doubt as to Santesson's identification and asserted that the mushroom in question may have been either *Psilocybe mexicana* or *Psilocybe cubensis*, or possibly a mixture of both.

It should be mentioned that the above noted observation on Santesson's alleged identification of the "honey-mushroom" is based on the writings of Schultes who mentioned that Santesson had used the word Hallimahl, which Schultes identified as Hallimasch, a European name for the "honey-mushroom." Ott (1993b)[85] states that Schultes was in error in his identification of this species (see Ott, 1993a [85]: footnote 6, page 298). Recently **Guzmán-**Dávalos and Guzmán (1991)[30] identified *Gymnopilus subpurpuratus* from Mexico as "staining green when handled." A related variety is *Gymnopilus purpuratus* Cooke & Masse, a species which has been identified as psilocybian. Both of these species macroscopically resemble the honey mushroom, so there is a possibility that Santesson may in fact have had a real hallucinogenic specimen after all.

Schultes' notes on specimens stored on a single sheet in the herbarium confused Singer (1958)[116]. As noted earlier, Schultes had identified one of his collections as *Panaeolus campanulatus* var.*sphinctrinus*, a possible divinatory mushroom. However, Singer then wrote that "the genus of *Panaeolus* was not used by the Mazatec Indians of the Huautla region either for magico-religious ceremonies or as a sacrament in shamanic healings." Additionally, Singer and Smith (1958)[118] wrote, "we must insist, that the phenomena which belonged in the class of cerebral mycetism in the terminology of Ford (1923)[19], and not fully identified (*Panaeolus campanulatus* var. *sphinctrinus*) (Schultes, 1939 [103], 1940 [104]), as being comparable with the hallucinatory-euphoric and lasting effects which have been described in literature as belonging to and coming from certain mushrooms of the genus *Psilocybe*. Aside from that we feel for certain that *Panaeolus campanulatus* var. *sphinctrinus* is not now and never has been used as a drug catalyst for divinatory purposes or religious ceremonies by present day Indians in Mesoamerica", nor was it used as a sacrament by their pre-Colombian ancestors.



Palácios, Singer, Wasson near Huatla de Jimenez

Fig. 4. Rolf Singer's assistant Palácios, Singer & Gordon Near Huautla (July 1957).

Schultes (1978)[106] later wrote that "Wasson and Heim, and Singer and Guzmán [all] failed to find*Panaeolus campanulatus* var. *sphinctrinus* in use and, as a result, have assumed that it should not be included in the list of hallucinogenically used Mexican mushrooms." The late French mycologist Roger Heim (1963)[32], also asserted that "the Indians do not take *Panaeolus campanulatus* var. *sphinctrinus* in their rituals", and Singer (1958)[116] after one short field trip, categorically stated that "*Panaeolus campanulatus* var. *sphinctrinus* is not used and perhaps, had been mistaken for *Psilocybe mexicana* Heim." The noted Mexican authority on the sacred mushrooms of Mexico, Gastón Guzmán (1977)[27], called *Panaeolus campanulatus* var. *sphinctrinus* a "false *teonanácatl*" while P. Antoine (1970)[6] claimed that this belief has spread and still exists. However, eight years later, Singer (1978)[117] still believed that no species of *Panaeolus* belongs to the group of Mexican hallucinogenic mushrooms which were known as *teonanácatl*. In 1979, Schultes wrote that "certain shamans and curanderas of the Mazatec and Chinantec Indians do employ the mushroom known as *Panaeolus campanulatus* var. *sphinctrinus* in curative and divinatory ceremonies." These *Panaeolus* species are known to the Indians as tha-na-sa, shi-to and to-shka. They are bell-shaped or ovoid-campanulate shaped in the cap and appear to be yellowish-brown in color. Several of the early Spanish codices noted above that one of the yellow mushrooms described was called *teonanácatl*. The author also found these latter two epithets used by the Mazatec in describing *Psilocybe mexicana*.

Specimens of *Panaeolus sphinctrinus* collected in Mexico by French Canadian mycologist György-Miklos Ola'h (1969)[82] were found to contain psilocine and Ola'h classified this species as 'latent' psilocybian.

However, as late as 1983, Guzmán still maintained that "in Mexico, no *Panaeolus* species is used as a sacred or divine mushroom among the Indians of Oaxaca, and that includes the Mazatec, Chatino, Zapotec, and Mixes, and of the Indians in the State of México, in spite of the fact that the species of *Panaeolus* are very common." *Panaeolus* species were collected independently as one of the sacred hallucinogenic mushrooms by two groups of investigators, Weitlaner's group and by Schultes and Reko. Previous chemical analyses of these collections revealed that some species of *Panaeolus* and even *Panaeolus campanulatus* var. *sphinctrinus* do contain the indole chemical psilocybine and psilocine (Ola'h, 1970 [83]; Ott, 1976 [84]; Tyler & Gröger, 1964 [130]). However, one should consider that in a single collection of a particular species, there may be more than two species represented - for example, one species might superficially resemble another, as in the case of *Panaeolina foenisecii* and *Panaeolus subbalteatus*, both of which resemble one another macroscopically.

Chapter 4. The Rediscovery of Entheogenic Mushrooms

Wasson's First Voyage

R. Gordon Wasson was born in Great Falls, Montana in 1898. The son of an Episcopalian minister, he became the first ethnomycologist in the world. His interest in wild mushrooms spanned more than fifty years, during which time he rediscovered the famed sacred mushrooms of Mesoamerica.

R. Gordon Wasson's interest in mushrooms began during his honeymoon in the Catskill mountains. Wasson and his Russian-born wife, pediatrician Valentina Pavlovna Wasson were hiking one day on a forest-trail when suddenly she espied a cluster of mushrooms which she recognized as being similar to ones she used to gather from the forest for dinner in her native Russia. Overcome with great joy, Valentina picked as many mushrooms as she could carry and that evening she prepared and served them with their evening dinner. Of course, R. Gordon Wasson declined to eat any of the "nasty toadstools" his new wife had gathered from the forest and told her he did not want to awake a widower, thinking that all mushrooms were poisonous (Wasson, 1957a [140]; Wasson & Wasson, 1957 [186]). It was for this reason that Gordon Wasson soon began to wonder why Slavic peoples love the mushrooms while some western Europeans abhorred them. Thus began the age of ethnomycology.

Photo: Linda Dear

Wasson, who worked as a journalist, soon became interested in banking and in 1928 began working as an investment-banker for Morgan Guaranty Trust. By the early 1950's, Wasson had become a vice-president of J.

P. Morgan & Company.

At that time, Wasson received an important letter from Eunice V. Pike, a missionary from the Wycliff Bible Translators. Pike had been living for many years among the Mazatec Indians in the southern Mexican State of Oaxaca. She wrote to Wasson informing him that there were Indian medicine-men and medicine-women who employed certain mushrooms in curative ceremonies. Pike informed Wasson that the use of these mushrooms probably originated prior to the conquest (see Pike & Cowan, 1959 [89]; Pike, 1960 [88]).

Wasson also received a letter from the noted Greek historian and scholar Robert Graves. Graves informed Wasson of two research articles written by Harvard ethnobotanist Richard Evans Schultes (see Davis, 1996 [12]), concerning a mysterious mushroom known to the ancient Aztec people as *teonanácatl*.

However, Schultes' papers concerning the use of these mushrooms by the Aztecs at the time of the Spanish conquest had generated little interest within the scientific community (Schultes, 1939 [103], 1940 [104]). In fact, the question of whether or not the mushrooms ever existed had been raised.

Wasson received another letter from his Italian printer which included a sketch of a Guatemalan mushroom-stone carving some 2000 years old. The drawing represented a sculpture of a man with a mushroom projecting from his head. The sculpture had been discovered somewhere deep in the jungles of Guatemala.

These startling new revelations piqued Wasson's interest immensely, so he then contacted Schultes (Pers. Comm. 1988)[108]: "One day I was home from the Amazon. Wasson phoned me for references to México." Schultes then went on to say "I sent him to Reko who was very helpful to him and who introduced him to Weitlaner. Thus Reko still had his contribution towards the study of the mushrooms." (Blas Pablo Reko, along with Schultes, had collected specimens of the alleged sacred fungi for herbarium deposit and Roberto Weitlaner was the first westerner to observe a sacred mushroom ceremony during the late 1930's).

In 1953, Wasson and his wife traveled to México. After arriving in the Mazatec country and inquiring about the sacred mushrooms they finally succeeded in attending an all night *velada* (as the ceremony is called by the Mazatec shamans or curanderos, who officiate and perform them). This first ceremony was conducted under the guidance of a Mazatec shaman named Don Aurelio Carreras. At the first ceremony, Wasson observed the procedures and took notes of what transpired, but was not allowed to join in nor partake of the mushrooms, However, he was very ecstatic over the performance, and felt no regret for not having been able to fully participate.

Wasson led two more exploratory excursions into México during the following two years. On his third trip to Oaxaca and his second to Huautla de Jiménez, Wasson and his photographer-friend Allan Richardson themselves in the tiny village of Huautla de Jiménez perched high in the Sierra Mazateca of Oaxaca. On the night of 29-30 June 1955, Wasson and Richardson became the first outsiders to partake of the sacred mushrooms.

After Wasson and Richardson had found lodging, they set out on separate searches, asking everyone they encountered for help in their mushroom hunt. After several hours of fruitless questioning of the natives, Wasson decided to ask a local government official to discuss the secrets of the mushrooms with him. He went to the local *municipio* (city hall), although he was aware that many government officials were dishonest and corrupt, especially when it came to matters involving foreigners. But Wasson felt he hadn't much to lose by approaching the official.

Wasson met a man working in the office of the mayor who was the town's sindico. The sindico is the number two man in a municipio, and since his boss was away on business, he was the acting mayor. His name was Cayetano García Mendoza. After exchanging introductions and greetings with García, Wasson in his polite and humble manner discussed with him general topics such as the weather, maize-crop prices, problems with the drinking water, the current prices of coffee, etc. It wasn't long before Wasson found himself leaning over the counter towards Cayetano and whispering the Mazatec name for the mushrooms.

With that Cayetano appeared bewildered and astonished. How could a foreigner have knowledge of such a well kept-secret that very few Mazatec people would mention so casually? But in answer to Wasson's question, Cayetano replied that "nothing could be easier", and then he asked Wasson "to come to my humble abode after four o'clock, when I am finished with my day's work, and I would be ever so glad to help you with your unusual request."

Later that afternoon, Wasson and his friend Richardson arrived at the home where Cayetano resided with his two younger brothers, who were waiting for the strangers to arrive. Emilio and Genero led them down the road to a spot not more than a hundred feet from Cayetano's house, where they found an abundance of mushrooms fruiting out of sugar-cane mulch.

While Richardson began photographing the mushrooms, Wasson picked several and placed them gently into a paste board box which he had brought along for this occasion.

Wasson Meets María Sabina

In the meantime, while Wasson was picking mushrooms, Cayetano proceeded to the home of his friend, Doña María Sabina, a sabia ('wise one' or 'wise woman'). Cayetano found Doña María alone in her home and related to her the events that had transpired earlier that day. He told her "that some blond men have traveled from afar in search of a sabia, and he quietly mentioned to her that the blond stranger had spoken to him in a soft quiet whisper, asking him in a discreet way, that he was seeking '*nti-xi-tjo* (Estrada, 1976)[17]. Although Cayetano was somewhat startled by the question asked of him, he confirmed his feeling of the stranger's request, explaining to Doña María that the blond stranger "knew of what it was that he was talking about." Cayetano felt that Wasson was definitely sincere in learning the secrets of 'nti-xi-tjo. Apparently Wasson's discretion with Cayetano had confirmed his sincerity in seeking knowledge about the mushrooms and their use, which had convinced Cayetano to talk with Doña María, so to convey to her the message from the blond strangers from a far-away land.

Cayetano then explained to Doña María that he told the visitors "I know a true wise woman." Cayetano asked Doña María if he could bring the strangers to her home so that she might teach them the true knowledge of the mushrooms. Doña María replied, "if you want to, I can't say no".

Years later, María Sabina stated that she felt compelled to accept Wasson's request because of Cayetano's official position, and she assumed Cayetano's visit to her humble dwelling that hot summer day was official business.

Many years later, Wasson wondered if María Sabina would have shared her knowledge of the mushrooms with him had Cayetano not intervened as he did. In 1971, Wasson read an interview with María Sabina which appeared in the European magazine L'Europe, published in Milan. It reported that when Cayetano had requested her aid in helping the foreigners, she did so because she felt she had no choice. But she also declared that when she was asked to meet them [Wasson and Richardson] that she "should have said no."

By late afternoon, Wasson, Richardson, and their friends Emilio and Genero, had finished picking the mushrooms and returned to Cayetano's home just as he was returning from seeing María Sabina. It should be noted that a few days later, Wasson offered to pay Cayetano for the fine hospitality and services they had provided Wasson and Richardson, but Cayetano and his wife refused. They informed Wasson that they had been happy to help, and "didn't do so for money."

Cayetano requested that Emilio accompany them to María Sabina's home to act as interpreter. Once there, Wasson opened his paste-board box and exposed the mushrooms he had just picked. Doña María cried out in joy upon seeing the honguitos which she so loved and adored. She held them in her small hands, caressing them while talking to them in her own language. Arrangements were soon made for a velada later that evening.

On the evening of June 29, 1955, Wasson and Richardson became the first white people to consume the sacred mushrooms of the ancient Mazatec people, in a ceremony held under the supervision of curandera Doña María Sabina, who performed for them a velada or vigil at the home of her friend Cayetano García.

Wasson later wrote, "we all ate our mushrooms facing the wall where the small altar table stood. We ate them in silence, except for Cayetano's father, don Emilio, who was consulting the mushrooms about his infected left forearm. He would jerk his head violently with each mushroom that he swallowed, and utter a smacking noise, as though in acknowledgment of their divine potency. I was seated in the corner of the room on the left of the altar. The señora asked me to move because the word would come down there..."

"I joined Allan immediately behind the señora, we took about a half hour to eat our six pairs of mushrooms. By eleven o'clock we had finished our respective portions, the señora crossing herself with the last swallow. ... At about 11:20 Allan leaned from his chair and whispered to me that he was having a chill. We wrapped him in a blanket. A little later he leaned over again and said, 'Gordon, I am beginning to see things,' to which I gave him the comforting reply that I was too."

"The patterns grew into architectural structures, with colonnades and architraves, patios of regal splendor, the stonework all in brilliant colors - gold and onyx and ebony - all harmoniously and ingeniously contrived, in richest magnificence extending beyond the reach of sight. These architectural visions seemed oriental, though at every stage I pointed out to myself that they could not be identified with any specific oriental country..."

"At one point in the faint moonlight the bouquet on the table assumed the dimensions and shape of an imperial conveyance, a triumphal car, drawn by zoological creatures conceivable only in an imaginary mythology, bearing a woman clothed in regal splendor. The visions came in endless succession, each growing out of the preceding ones. We had the sensation that the walls of our humble house had vanished, that our untrammeled souls were floating in the empyrean, stroked by divine breeze, possessed of a divine mobility that would transport anywhere on the wings of a thought. Only when by an act of conscious effort I touched the wall of Cayetano's house would I be brought back to the confines of the room where we all were, and this touch with reality seemed to be what precipitated nausea in me."

What Wasson experienced during his first *velada* convinced him that he would never repeat it, but a few nights later he asked Doña María if she would perform again in order that he might record the proceedings. On this occasion Allan Richardson declined partaking of the sacred mushrooms so he might better photograph the session.

Doña María referred to Wasson as "Basson" and she allowed the taking of photographs by Richardson on the condition that Wasson would not profane her by allowing other people access to the photographs taken during the ceremony. She requested that Wasson only share them with his closest and dearest friends and that no others should see them. Eventually their publication in *Life* magazine made María Sabina known to the world. Although this event brought thousands of people into Oaxaca in search of these entheogenic fungi, María Sabina never expressed any resentment toward Wasson as a result.

On the night of July 5, 1955, Wasson's wife Valentina and their 19 year-old daughter Masha (in his 1980 book, The Wondrous Mushroom: Mycolatry in Mesoamerica[174], Wasson mistakenly reported that Masha was then only 13 years old) became the first westerners to consume entheogenic mushrooms outside of a ritual setting. This would appear to be the first reported incident involving non-traditional use of psychoactive mushrooms (Wasson V., 1958)[185].

Six weeks later, having returned to New York, Wasson again felt compelled to ingest the mushrooms from México, to ascertain whether dried specimens he had brought back were still active. This was Wasson's third experience with the sacred mushrooms.

During Wasson's many excursions into Mesoamerica, always seeking new information on the traditional use of entheogenic mushrooms he endeavored to link the enigmatic mushroom-stones of Central America to ritual mushroom use by Mayan peoples to cultic use in primitive Mayan societies.

Wasson believed there was a link between the mushroom effigies and the use of entheogenic mushrooms in Mesoamerica. Once during an excursion to the village of Juxtlahuaca, México, Wasson photographed a young Mexican girl grinding mushrooms on a matate or grinding stone. The mano she used to grind the mushrooms and her position while doing so, was similar to the posture and form represented on one of the mushroom-stones unearthed in Guatemala (Furst, 1986)[20].

Studies by Villacorta & Villacorta (1927)[135], Johnson (1938)[46], Schultes (1939 [103], 1940 [104]), Singer(1949)[114], Wasson & Wasson (1957)[186], de Borhegy (1961b)[13], de Borhegy (1962)[14], Lowy (1971 [71], 1972 [72]), Ott (1976)[84], Mayer (1977)[74], Weil (1977)[137], Wasson (1980)[174], and others who followed the Wassons brought attention to ancient frescoes, paintings, illustrations and gold-work depicting sacred mushrooms (Schultes and Bright, 1979)[110]. The mushroom stones and other art works, including depiction's of mushroom motifs in paintings and sculptures gave ample proof that the entheogenic mushrooms had an important role in the development of spirituality in pre-Colombian cultures.

It is conceivable that some 3000 years ago in Mesoamerica, a sophisticated form of shamanism had flourished and prospered, revolving around the ritual use of entheogenic mushrooms and other visionary inebrients as major foci in the development of Mesoamerican cultures.

Wasson led a total of 10 field-trips into the wilds of Mesoamerica (1953-1962), gathering mushrooms and information on their use in their rituals by the various cultures who used them. Wasson sought the collaboration of many eminent scholars to assist him in these investigations. Specialists who assisted Wasson included: Roger Heim, Gastón Guzmán, Roberto Weitlaner and his daughter Irmagard Weitlaner Johnson, Guy Stresser-Peán, C. Cook de Leonard, W.S. Miller, Searle Hoogshagen, B. Upton and Albert Hofmann who was director of Natural Products at Sandoz in Basel and had discovered LSD before isolating psilocybine and psilocine.

CIA Mole James Moore - Spies on Wasson in the Search for Mind-Control Drugs

"Nervous and paranoid" correctly describes a "short-order chemist" for the CIA, James Moore (Lee & Shlain,1985 [67]; Marks, 1979 [73]; Stevens, 1987 [124]), who secretly infiltrated one of Wasson's small expeditions into the Sierra Mazateca in 1956.

A scientist from the CIA's "Project ARTICHOKE" had traveled to México in search of a so-called "stupid bush" and other plants which might derange the human mind, politically useful to control enemies minds in war time. Large quantities of morning-glory seeds were sent to CIA laboratories for analysis by CIA scientists searching for compounds useful for extracting confessions, locating stolen or lost objects, perhaps even predicting the future. Visionary mushrooms were of special interest in these investigations. According to documents obtained via the Freedom of Information Act, James Moore was an expert in chemical synthesis who worked for the CIA. In 1956, Moore invited himself into one of Wasson's expeditions to México. He offered Wasson a grant for $2,000 dollars from a CIA-front known as the Geschickter Fund for Medical Research, Inc. In 1955, Wasson had declined to collaborate openly with the CIA.

Moore did not enjoy his single mushroom experience, perhaps due to the fact that he was not who he represented himself to be. Mayhaps this fact got the better of him, and under the influence of the mushrooms he saw himself as he really was. According to Moore, "I had a terrible cold, we damned near starved to death, and I itched all over. There was all this chanting in the dialect. Then they passed the mushrooms around, and we all chewed them. I did feel the hallucinogenic effect, although 'disoriented' would be a better word to describe my reaction."

Moore collected specimens for his CIA-sponsored research and returned to Maryland, where he endeavored to isolate for the CIA the active principle of both the mushrooms and morning glory seeds. Unfortunately for Moore he was unable to find the active ingredients with the fungi and lucky for the world that he didn't find them since they would of most likely been used as tools of mind war under the direction of the CIA.

In spite of the duplicitous antics of the CIA which predictably came to nothing, Wasson and collaborators documented traditional use of the sacred mushrooms in Oaxaca, Mexico and other states. Wasson and Singer found that several species and/or varieties of mushrooms were still employed ceremonially by some dozen Indian tribes belonging to various linguistic groups. Some of the Mexican Indians spoke no Spanish nor possessed a written language. The following indigenous groups used the sacred mushrooms: Mazatecs, Chinantecs, Chatinos, Zapotecs, Mixtecs, Mixes (Mijes), Nahuas and Otomies and possibly also the Tarascans of Michoacán.

Different Oaxacan Indian tribes prefer different species of mushrooms, and the attendant rituals vary somewhat from village to village. Even within a given tribe not all shamans will use precisely the same mushrooms, depending on what species be available at any given time. More than one species may be used perhaps for specific purposes, during a particular curing ritual (Wasson & Wasson, 1957)[186].

The Wassons' discoveries regarding the visionary mushrooms in México became public knowledge in 1957, with the publication of a two-volume book *Mushrooms, Russia and History*, limited to 512 copies and never reprinted. Some university libraries have copies in rare-book collections.

Simultaneous with publications of *Mushrooms, Russia and History* were two popular articles in Life magazine (Wasson, 1957a)[140] and This Week magazine (Wasson, V. P., 1958b)[143]. These articles by Gordon Wasson and the other by his wife, captured the beginning of the Psychedelic Era. Collectors of the Wassoniana have been known to pay up to $50.00 for a mint-copy of this particular issue of *Life*.

A third presentation to the world occurred in 1958, when Gordon Wasson and Roger Heim, together with Albert Hofmann and other collaborators, published *Les Champignons Hallucinogènes du Mexique*, completed by a second volume ten years later, *Nouvelles Investigations sur les Champignons Hallucinogènes*, both written in French, some [parts of which originally appeared as papers in *Comptes Rendus Acad. Sci*. and *Revue du Mycologie*.

R. Gordon Wasson died on Dec 23, 1986, and is survived by an adopted son and daughter.

Chapter 5. María Sabina

Saint Mother of the Sacred Mushrooms

Almost forty years have passed since the eminent ethnomycologist R. Gordon Wasson stumbled into the tiny Oaxacan village of Huautla de Jiménez in search of *teonanácatl*, the magic mushroom of Mesoamerican folklore. His lifetime of studying mushrooms and current three year quest in the foothills of Oaxaca came to an end at the doorway of a small earthen hut with crumbling mud walls and a sunken thatched roof. This hut was the life-long home of Doña María Sabina, the most renowned curandera in all of history.

According to anthropologist Joan Halifax (1979)[31], "For many decades she had practiced her art with the hallucinogenic mushrooms, and many hundreds of sick and suffering people came to her wretched hut to ingest the sacrament as she chants through the night in the darkness before her alter."

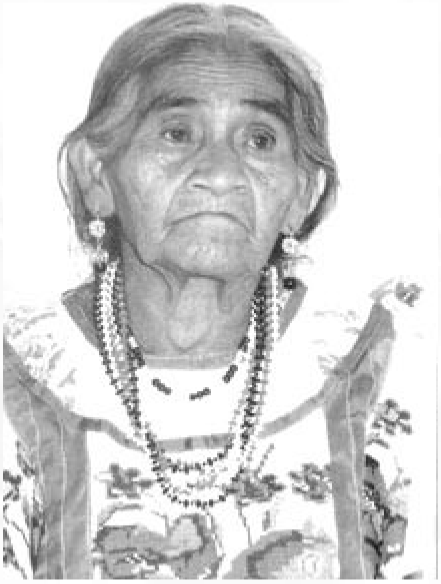

Fig. 7. María Sabina.

Being a kind soul, Doña María welcomed Wasson into her hut and shared the secrets of the sacred mushroom. How could she know that this small, innocent gesture of generosity and kindness would radically change her life and the course of history forever. Despite Wasson's attempts to keep Doña María's identity a secret, the story of the Mazatec witch and her mushrooms of wonder spread throughout the west like wildfire - from the halls of Harvard to the back-beat streets of big town America (when R. Gordon Wasson first wrote of María Sabina and her Veladas in Life magazine (13 May 1957), he referred to her as Eva Mendez, a pseudonym intended to protect her from scalawags and thrill-seekers who might disturb or disrupt her life and those around her).

Wasson's story inevitably piqued the interest of many people. Hoping the mushroom could be a powerful tool in chemical warfare, the CIA sent an undercover agent to Huautla de Jiménez to collect specimens (Marks, 1979)[73]. Again, Doña María shared her secret. What else could she do? The mushroom had shown her that the Westerners would never give her peace. Reluctantly she gave in, but with each desecration of the sacred mushrooms she could feel her curing powers fading.

She knew the Westerners would be coming by the dozens (doctors, scientists, thrill-seekers, spiritual pilgrims) all looking for truth, salvation, the curing magic, or even the face of God. Resigned to her fates, Doña María patiently accepted each weary searcher into her home and performed the velada, the all-night vigil, for them. Each time she gave the visitors what they were looking for. Each time she gave away a bit of herself.

Now all that's left of Doña María are memories, memories of the humble woman who inspired the lives of Tim Leary, Ralph Metzner, Andrew Weil, Jonathan Ott, and countless others. Beyond her memory only the mushrooms remain, the tiny magic toadstools Doña María spent her life mastering. Now that she's gone, the only way to find her is through them, through the sacred ceremonies of Mazatec wizards and healers.

Can you make out her face, dark and chiseled with age? Can you hear her songs and chants cutting through the still blackness of night? Her spirit is out there, caught in an endless rainbow spiral of wisdom and beauty. Her ghost is waiting to be heard. Just reach out...

Childhood

Wasson (Estrada, 1976)[17] reported that María Sabina was born on the 17th of March, 1894. According to parish records María was baptized exactly one week after her birth. Her mother María Concepción said her daughter's birth was the day of the Virgin Magdalene (July 22).

According to a verbal account given to Señor Alvaro Estrada, Doña María first consumed the sacred mushrooms with her sister María Ana at an early age (possibly somewhere between the ages of 7 to 9-years-old). Doña María Sabina recalled that she and her sister were out in the woods tending the family's animals when they stopped under a tree to play games in the shade as little children often do when by themselves with no adults around. María looked to the ground and noticed several beautiful mushrooms growing under the tree and realized they were the same mushrooms used by a local curandero Juan Manuel to cure the sick.

Doña María reached down to the earth and carefully harvested several of the mushrooms exclaiming "if I eat you, you, and you, I know that you will make me sing beautifully." She slowly chewed and swallowed the mushrooms, then urged her sister María Ana to do the same. Slowly, young María began to realize that the mushrooms contained a very potent magic, one that she would never forget.

In the following months Doña María and her sister consumed the fungi several times. Once her mother had found her laughing and singing gaily and asked of her "what have you done?". However, she was never scolded for eating the mushrooms because her mother knew that scolding would cause contrary emotions.

According to Joan Halifax (1979)[31] Doña María was eight years old when her uncle fell sick. Many shamans in the surrounding Sierras near her village had attempted to cure him with various herbs, but his condition only worsened. Doña María remembered that the mushrooms she had eaten while playing with her sister had told her to look for them if she ever needed them and that they would tell her what to do when she needed help.

Doña María went to collect the sacred mushrooms and returned to her uncle's home where she ate them. Immediately, Doña María was swept away into the world of the mushrooms. She asked them what was wrong with her uncle and what could she do to help him get well. According to Doña María, the mushrooms told her that an "evil spirit" had entered the blood of her uncle and possessed him. She would have to give him a special herb, but not the same herb which the other shamans and curanderos had previously given him. Doña María then asked the mushrooms where the herbs could be found and the mushrooms told her that there was a place on the mountains where the trees grew tall and the waters of the brook ran pure. In this place in the earth are the herbs which will cure your uncle.

Doña María knew the place the mushrooms had shown her and ran from her uncle's hut to find the herb. Just as the mushrooms had shown her, the herb was there. When she returned to her uncle's home she boiled the herbs and gave them to her uncle. Within a few days, her uncle was cured, and María knew this would become her way of life.

As Doña María grew older she became fully initiated into her role as a sabia (a wise one). She quickly became respected in her village as an honest and powerful sabia, and in her community she was a blessing to those who sought her services. For decades she practiced her healing arts, and countless hundreds of sick and suffering people sought out her magic. Except for her three marriages, where she was expected to care only for her husband, she continued her sacred practices throughout her life.

Being of the Mazatec (Nahua-speaking) people, María Sabina performed her ceremonies in Mazatec (in This Week magazine, Valentina Wasson, 1958 wrote that the ceremony was spoken in Mixtec). Like the pseudonym of Eva Mendez which R. Gordon Wasson gave to María Sabina, this latter report was also published with the intent of keeping her identity a secret from those who would abuse her livelihood.

Like many of the Mazatec shamans, curanderas, and healers, María Sabina referred to the mushrooms as xi-tjo, si-tho or 'nti-xi-tjo, meaning "worshipped objects that spring forth" ('nti = a particle of reverence and endearment, and xi-tjo = that which springs forth). Some Mazatecs refer to the mushrooms by saying "that the little mushroom comes of itself, no one knows whence, like the wind that comes, we know not when or why."

The sacred mushrooms which María Sabina used during an all night velada (vigil) are usually harvested in the evening when the moon is full, although sometimes they are gathered in the day (see footnote 1 at the end of this chapter). Mushrooms gathered in the moonlight may sometimes be harvested by a young virgin.

After the mushrooms are collected they must be taken to a church. There they are placed on an alter to be blessed before the holy spirit. If the virgin who picked the mushrooms comes upon the carcass of a dead animal, one which had died along the path she follows, she must then discard the mushrooms and find a new path back to the field where the mushrooms grew. There she must gather up more fresh mushrooms and then find a new trail leading back to the church, hoping and praying that she will not come across any more dead animals. Once the mushrooms have been consecrated on the alter they are ready for use.

The *velada* would begin in total darkness so the visions would be bright and clear. After the mushrooms were adorned and blessed by María Sabina, she would slowly pass each one through the swirling smoke of burning Copal incense. The mushrooms are always consumed in pairs of two, signifying one male and one female. Each participant in a ceremony consumes five to six pairs; though more will be given if requested. Because the spiritual energies of the sabia would always dominate the *velada*, María Sabina would normally consume twice as many mushrooms as her voyagers, sometimes up to twelve pairs.

In the tradition of Mazatec shamans and curanderas, María Sabina would first chew the mushrooms, hold them in her mouth for a while, and then swallow them. The mushrooms should be consumed on an empty stomach and eaten over a 20-30 minute period. She decides who is to take them and the spiritual energies of the sabia always dominate the sessions. These sessions are usually conducted at night, in total darkness so that the visual effects from the mushrooms will be fully effective. A candle or two may be used but is seldom necessary. As the energies of the mushrooms pour themselves into the spiritual voyagers, Doña María would chant, slap, and pound her hands against various parts of her body, creating many different resonant sounds while invoking ancient incantations.

The thumping chants would totally fill the space of her hut and go beyond the walls to the far horizons of infinity. The chants were used to invoke the mushrooms power and varied depending on the various illness or ailment which the healer is called upon to cure (see footnote 2 at the end of this chapter) (Krippner & Winkelman, 1983 [52]; also see Aromin, 1973 in Krippner & Winkelman, 1983). Being a devout Catholic her entire life, she would often blend ancient Mazatec rituals with Christian elements, such as the Eucharist of the Catholic religion. When the mushrooms were not in season, María Sabina would employ other sacred plants with Christian rites (see footnote 3 at the end of this chapter).

All accounts of María Sabina attest to the fact that she was indeed a humble and holy woman - a saint. Wasson himself described Doña María as "a woman without blemish, immaculate, one who has never dishonored her calling by using her powers for evil...[a woman of] rare moral and spiritual power, dedicated in her vocation, an artist in her mastery of the techniques of her vocation (Wasson,1980)[174]." In her village, Doña María was exalted as a "sabia" (wise one), and was known among many as a "curandera de primera catagoria" (of the highest quality) and an "una señora sin mancha" (a woman without stain).

Father Antonio Reyes Hernandez is a man of the cloth, a man with the love of God in him, and the Bishop who resides in the parish of the Dominican church which Doña María belonged to. In 1970, when Father Antonio had just completed his first year as the Bishop of Huautla, Alvaro Estrada (1976)[17] had inquired of Father Antonio if his ecclesiastic elders in the church hierarchy opposed the pagan-like rites of the shamans and sabias in Oaxaca and elsewhere in México as his conquering predecessors had during the last three centuries. Father Antonio replied that "the church is not against these pagan rites - if they may be called that. The wise ones and curer's do not compete with our religion. All of them are very religious and come to our mass, even María Sabina. They don't proselytize; therefore they aren't considered heretics, and it's not likely that any anathema's will be hurled at them."

Father Antonio never admonished or condemned her for her work in the village. He was aware that her rituals and practices had been handed down to her through the ages from her ancestors. He also knew that her services were valid treatments for those who sought her shamanic talents. Father Hernandez always recognized her work with the sick and suffering as the mark of a true Christian - one willing to help the less fortunate. Although he knew that Doña María used the mushrooms and pagan practice to heal and cure, he also understood that María Sabina's nature was not of a demonic spirit, "nor was it" satanic or even heretic. He appreciated her spirituality and treasured her work as a long termed good standing member of his church.

A Bishop interested in experiencing the visionary effects of the mushrooms came to María seeking guidance. However, he was turned away since it was not the season for the mushrooms and there were no mushrooms available for a ceremony. The Bishop had asked María Sabina if she would teach her children her talents. María Sabina told the bishop that her talents could not be taught to others but could only be achieved by those whose wisdom had been already naturally attained. However, it is said that before her death in 1985, Doña María spent most of her final years teaching others her talent in the communication of the mushrooms (Krippner (1987) [1983]))[50].

As Doña María believed in the power of Christ, so she also believed in the power of the mushrooms. She gave of herself to her church and likewise to the mushrooms. While working for the church, her mass was spoken in Latin and her chants were always spoken in Mazatec, and it should be remembered that although Doña María was unlettered she was not illiterate.

Doña María was quick to notice that Wasson and his friends, being the first foreigners to (seek) out the 'saint children' (mushrooms), had no sickness or illness to cure. They came only out of curiosity, or to find God (Estrada, 1976)[17]. Before Wasson and the others strangers came to Huautla, the mushrooms had always been used to treat the sick. Doña María foresaw the diminishing effects in her ability to perform her duties. She claimed that as more outsiders used the mushrooms for pleasures, or "to find God," the magic of the mushrooms slowly ebbed from her spirit. Her energy, and the energy of the mushrooms, was slowly fading away.

While María Sabina felt this debasement of her powers and relationship with the mushrooms was caused by the young foreigners who frivolously sought out and abused the sanctity of the sacred mushrooms, it should be noted that seeking and finding one's own god may also be a cure for many of mankind's psychological ills, woes, and faults.

The Coming of the Foreigners

In the beginning, the first travelers who came to Oaxaca in search of the sacred mushrooms were polite and kind to María Sabina. They displayed mutual respect for her personage. Many came bearing gifts and pesos for her services. Doña María received many people (young and old) into her home and performed for them the sacred ceremonies of her ancestors. One of the greatest gifts one could present her with for her services were photographs of her and her family. Some travelers would offer her gifts of no value and many gifts she considered useless. One tourist offered her a large dog in payment for her time, but she refused. She was too poor to afford feeding the animal. Although poor, María Sabina was spiritually enriched.

Doña María had also been widowed twice in her lifetime and once one of her sons had been brutally murdered before her very eyes. She claimed to have witnessed the crime in a vision prior to its happening. This supports the Wasson's assertions that the mushrooms have telepathic properties. In 1984, María Sabina had found a third husband.

Her three room home in Oaxaca where Doña María performed her ceremonies was created of mud with a straw thatched roof and a dirt floor. The interior of her humble dwelling whose walls were crumbling with age had uneven earthen floors which were almost barren of furniture except for the simplest alter. A candle provided the only light since there was no electricity. On a few occasions she was presented with a mattress or two, but she rarely accepted gifts beyond the value of her daily needs.

After Wasson published literature on his rediscovery of an ancient practice which utilized hallucinogenic mushrooms ritualistically in Oaxaca, many young foreigners from the United States, Canada, Europe and South America, began their long treks and tedious pilgrimages into Mexico. Soon Doña María took notice that many native Indians and Mexicans alike were debasing her customs by peddling mushrooms to the tourists in order to feed themselves and their families. During this period, many came seeking the mushrooms and many came only to be turned away.

By 1960, María Sabina realized that she was known the world over. This new found fame brought her much grief, and the agony it caused her soul was evident in her eyes and face. It brought turmoil and profanation to her village and upon her work.

The lack of respect and the total disrespect which the foreigners displayed towards her "saint children" shook the very foundations of her wisdom, strength, and world. Like the ancient mysteries of the "temple of Dionysus" where silence of the ancient rites was golden, María Sabina claimed that before Wasson came, "nobody spoke so openly about the 'saint children'. No Mazatec before ever revealed what he or she knew about this matter (Estrada, 1976)[17]".

After Wasson had attended his first voyage with her, every one seemed to know who she was and what she did.

When Wasson was first introduced to María Sabina in 1955, it was only because of an introduction by her friend Cayetano (Wasson, 1957 [140]; Wasson, 1980 [174]; Allen, 1987 [2]). He was a trusted friend, and María felt that Cayetano's requesting her to meet with the stranger who had traveled from afar in search of a "sabia" was harmless. Upon first meeting Wasson, María Sabina believed him to be a sincere and honest man, and felt that he would respect her ways and never bring shame to her world. Although she cautiously accepted Wasson when Cayetano approached her, she would later accept many into her home, and there were also many whom she would turn away.

María Sabina placed her trust in Wasson and his friends, especially when she allowed them to tape and photograph her during an all night mushroom *velada*. She gave Wasson and Alan Richardson, his photographer, permission to tell her story to others. Doña María hoped that Wasson would not profane her image nor divulge her anonymity to the world in an improper manner. Because Doña María neither read nor wrote (her language has no written words) she would never fully know exactly what Wasson had written of her life.

By 1960, Doña María had decided that if "foreigners come to her without any recommendations [whereas Wasson had one], she would of course still show them her wisdoms" (Wasson, 1980)[174].

During the 1967 summer of love, many drugs and rampant drug use spread from out of the Haight-Ashbury district of San Francisco into the main stream continental United States of America. Many young hippie types and college students soon traveled to México in search of the magic mushroom which they had read about or heard about from their friends (Swain, 1962 [129]; Finkelstein, 1969 [18]; Lincoln, 1967 [69]; Sandford, 1973 [101]; Weil, 1980 [138]).

Doña María soon began to understand the breadth of her fame when over the years she remembered the pilgrimage of "the young people with long hair who came in search of God" but lacked the respect for the mushrooms and greatly profaned them.

Later, Doña María realized that "the young people with long hair didn't need [her] to eat the little things." She said that these "kids ate them anywhere and anytime [they could find them], and they didn't respect our customs." Doña María also claimed that "whoever does it [mushrooms] simply to feel the effects can go crazy and stay that way temporarily, but only for a while."

Wasson recognized the traditional values of the religious motivations of the Mazatec shamans and sabias, explaining that "performing before strangers is a profanation and that the curandera who today, for a fee will perform the mushroom rite for any stranger is a prostitute and a fakir" (Metzner, 1970)[75], yet María Sabina did perform rituals for strangers, sometimes for a fee and sometimes not. At times, she had been known to charge for services which she used to provide for free.

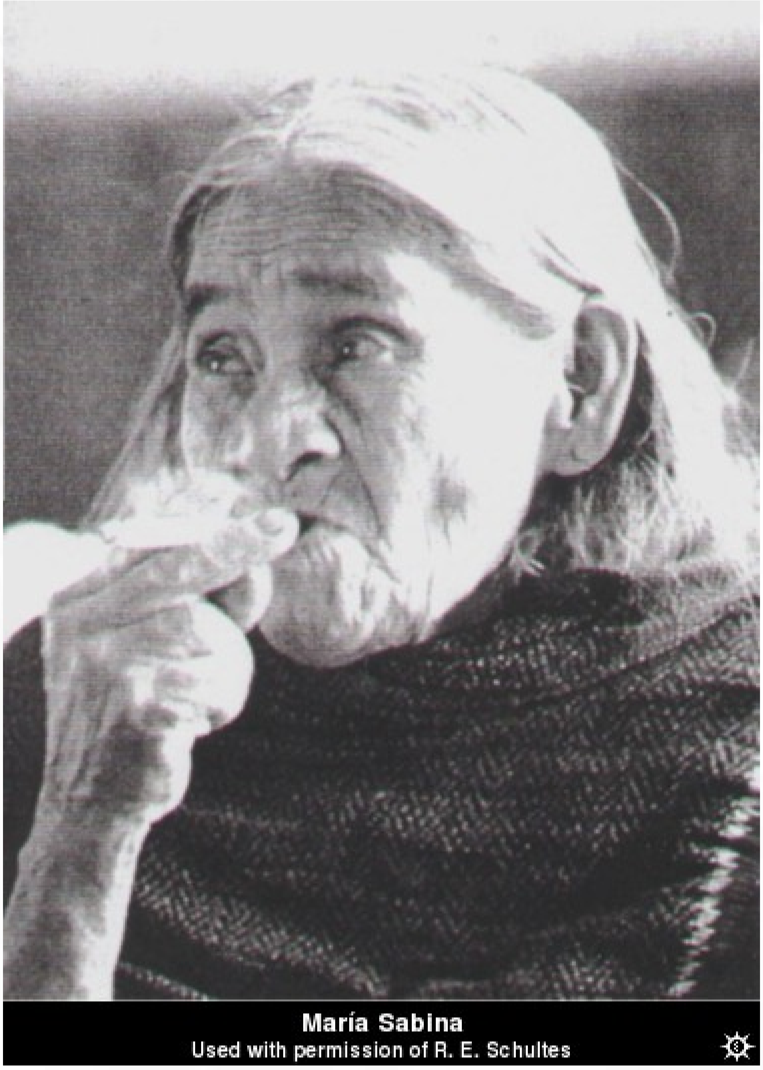
At one point an American tourist once ate too many mushrooms and completely flipped out. He caused "much turmoil" and anxiety in an otherwise once quiet and peaceful community. Another tourist, with a live turkey dangling from his mouth, ran stark raving mad through the streets of Huautla. This incident necessitated intervention by local policia who apprehended him before he could do harm to himself or others. This incident, along with several others, soon led to the expulsion of thousands of long haired thrill seekers from Mexico.

The actions of these young people created many scandals. With the influx of drug-oriented young people, local authorities began to prohibit the use of mushrooms. By 1976, the thousands of foreign invaders began to drastically diminish, allowing the federales to slowly move out of the area. To the native peoples of Oaxaca, the bad elements had finally subsided and peace had once again returned to the village.

Throughout the years Doña María had been hassled many times by local government officials because of her use of the sacred mushrooms with the foreign intruders.

On several occasions she was arrested and jailed for her activities and on one occasion her home was burnt to the ground. A journalist who interviewed her in 1969, tried to intervene for her in this matter. He personally requested that the governor of Oaxaca "leave in peace the most famous shamaness in the world, whom anthropology and escapism have ruined" (Estrada, 1976)[17].

May the Force be With You



María Sabina

Fig. 8. María Sabina.

As noted above, Federal authorities, army and police included, began the expulsion of hundreds of young foreign travelers, who came to Mexico "in search of the mushrooms and God" (Jones 1963 [45]; Unsign., 1970 [132]).

Doña María believed in the sacred force of the mushrooms with the same enthusiasm that many people came to believe in "the Force" of George Lucas and Luke Skywalker. As the years passed since Wasson first came to Huautla de Jiménez, Doña María felt the force of the mushrooms diminish within her spirit. Doña María realized that with the coming of the white man, the mushrooms were losing their meaning. Doña María claimed that "before Wasson, I felt that the 'saint children' elevated me. I don't feel like that anymore. The force has diminished. If Cayetano had not brought the foreigners ... the 'saint children' would have [probably] kept their powers. From the moment the foreigners arrived, the 'saint children' lost their purity. They lost their force; the foreigners spoiled them. From now on they won't be any good. There is no remedy for it."

This revelation from María Sabina most assuredly rings of the truth. The debasement of the mushrooms by casual thrill-seekers is widespread throughout the planet. Apolonio Teran, a fellow sabio (wiseman) was once interviewed by Alvaro Estrada. Estrada asked Apolonio about the breach of sanctity of the mushrooms by debasement wondering if the mushrooms were still considered to be a sacred and powerful source of medicine.

Apolonio claimed that "the divine mushroom no longer belongs to us [the Indians of Mesoamerica]. It's sacred language has been profaned. The language has been spoiled and it is indecipherable for us... Now the mushrooms speak NQUI LE [English]. Yes, it's the tongue that the foreigners speak... The mushrooms have a divine spirit. They always had it for us, but the foreigners arrived and frightened it away..." Later Wasson (1980)[174] agreed that "since the white man came looking for the mushrooms, they have lost their magic." This could mean that the magic is gone forever among the shamans and native peoples who worship them.

Wasson believed that Doña María's words rang of truth. In exemplifying her wisdom, Wasson stated that "a practice carried on in secret for three centuries or more has now been aerated and aeration spells the end (Estrada, 1976)[17]."

Before Wasson's death (December, 1986), he felt that he alone was responsible and accountable for what must surely be a sad and tragic end to a culture whose traditions and customs involving the sacred use of teonanácatl spanned and flourished majestically for almost three millennia. It now appears that the use of mushrooms among native peoples of Mesoamerica are in their final stages of extinction. Soon the cultural use of mushrooms and other sacred plants could vanish from the face of the earth.

Wasson's eloquent approach in presenting María Sabina's world to the public is without a doubt, beyond reproach. He presented a most unique tale of María Sabina and her sacred mushrooms. His writings took us where no man had gone before and he presented to the world her story as no other person would have. Wasson brought María Sabina and her world into view of the public eye. He told of her chants, her way of life, her reasoning, and of her magic with her fellow village members, all who visited her seeking her advice and divination. Wasson orated her virtues with the highest respect and the finest regards and what he put to paper was only the truth as she revealed it to him and as he first saw and heard it.

Wasson knew that María Sabina was relevant to the balance of nature within her community. He held an extreme profound reverence for the woman and her work. At the same time he displayed features of her spirituality without bringing shame upon her heritage. He presented her to the world with an integrity that brought enchantment with what he wrote. Wasson's discoveries in Mesoamerica and his integral interpretations are what María Sabina would have written and described if she had been able.

Because of Wasson's intrusion into her life and the myriad who followed, a part of María Sabina's world and way of life was taken away. However, the vast treasures of ethnomycological knowledge and wisdom which Wasson extracted from her world became public only because she shared it with the outsiders. This knowledge will now remain a part of history because it was recorded by an honorable man who cared about what he had observed, experienced, and wrote of.

María Sabina was many things: an earth woman, a mother, a sabia, a poet, a healer, a curer, a believer, an achiever, and a curandera who stood at the very edge of her universe and glimpsed the secrets and meaning of life. Doña María had shared her secrets of magic and plant knowledge with the outside world. Only through hope and prayer will the benevolence she provided to the world be fully understood and appreciated. Through the pursuance of R. Gordon Wasson's persistency in following his dream of the trail of the magic mushrooms, Doña María has truly presented mankind with a magical key (mushroom) concerning some plausible answers surrounding some of the mysteries of our religious beginnings and maybe the origin of the earth.

Doña María may be gone, but her spirit and her wisdom still remain. Reach out and take the wisdom she was so willing to share. Take it with care and share it with love and respect. Can you see her face in the dark? Can you hear her chanting?

Notes

1. María Sabina used many different species of the sacred mushrooms for divination. She preferred *Psilocybe mexicana* Heim, the preferred species of the Mazatec shamans. However, the mushrooms which she shared with R. Gordon Wasson and Alan Richardson were *Psilocybe caerulescens* var. *mazatecorum*.
2. The sacred mushrooms are usually consumed when fresh but may sometimes be served when dried. In pre-Columbian México the mushrooms were served and eaten with chocolate and/or honey. A trait left over from the times of the Aztec priests, a cultural tradition handed down through centuries of use by their ancestors. In some regions like Juxtlahuaca, the Mixtec shamans grind the mushrooms into a fine powder and brew a tea with the ground material.

   Metzner (1970)[75] reported that "in the land of the Mixe (Mijes) there are no curanderas. Most of the Mixe know and share the secret of the mushrooms and how to use them. One might take the mushrooms alone but will always have an observer present, to help guide him or her in their journey. The reason one might seek the mushrooms are medical and divinatory: to find a diagnosis and/or cure for an otherwise intractable condition; to find lost objects, animals or people; to get advice on personal problems or some great worry."
   Although María Sabina had gracefully preserved within her the power and wisdom derived from her relationship with the mushrooms, she only used them for good purposes. She also incorporated old traditions, blending them with certain Christian values and ideologies to divinate a particular situation, thereby diagnosing it correctly for the person in need of healing.

   Singer and Smith (1958)[116] believed that "the religious healing ceremonies of the Mazatec are also directed by the curanderos [or curanderas], but more emphasis is given to the revelations obtained by the intoxicating persons, so that the use of the mushrooms in Huautla is at least partly divinatory rather then medical." Metzner (1970)[75] felt that "the use of mushrooms for the [sole] purpose of divination is accepted as a matter of fact. Demonstrations of its capacity to bring about altered states of consciousness combined with brilliant kaleidoscopic visions of glorious colors and patterns have been convincingly made." Aguirre-Beltran (1955) claimed the healer (whether shaman or curandera) "looked not at the context of what it was in these plants that make them do their magic, but felt that the Indians' thoughts on these plants possessed two different aspects in their use in treatment:
   1) the mystical force that the plants projected into ones mind; and
   2) the actual diagnostic power that the use of the plant brings out."
   Beltran was positive that the "sacred herbs, deities in themselves, act by virtue of their mystical properties; that it is not the herb itself that cures but the divinity, the part of the divinity or magic power with which it is imbued."
   In considering the outcome of these ancient pagan practices in traditional societies, we cannot forget that in María Sabina's world the velada and mushrooms that she feeds upon provide the guideposts to her spiritual existence. Doña María had already foreseen the diminishing effects in her ability to perform her duties as the mushrooms became known to the outsiders. She claimed that the more outsiders who used the mushrooms for pleasure or "to find God" caused the magic of the mushrooms to slowly ebb from her spirit. Her energy and the energy which were within the mushrooms was slowly fading away. Metzner (1970)[75] wrote that the "practice which she employed was all that remained among a primitive and illiterate people today of a practice which was once so widespread throughout the mighty and powerful [Aztec] empire" that 300 years ago, a catholic conqueror named Cortez and a hoard of conquistadors almost succeeded in obliterating from the face of the earth any knowledge pertaining to their use and existence.
3. When the mushrooms are not in season, Mazatec shamans and curanderas (including María Sabina) employ several other common psychotropic plants for divination.
   One such plant is *Salvia divinorum*, a member of the mint family which is rich in essential oils. Swiss chemist Albert Hofmann (1980)[38] reported that it was a plant used ceremoniously by María Sabina. Mazatec shamans and sabias refer to this plant as "Hojas de la Pastora" (leaves of the shepherdess). Doña María Sabina referred to it as "la hembra" (the female) (Wasson, 1962b)[153]. *Salvia's* divinatory powers can be experienced by rolling twelve to sixteen mature leaves into a plug and holding it between the cheek and gum for fifteen minutes. Profound visual effects will be noticed with eyes closed or in total darkness. Dried *Salvia* leaves can also be smoked for milder effects.
   When the *Salvia* herb is not available for use in divination, the Mazatecs employ two different species of *Coleus* found in Oaxaca. *Coleus pumilus* is referred to as "el macho" (the male). Two other varieties of *Coleus blumi* are referred to as (1) "El nene" (the children) and (2) "el ahijado" (the godson). The psychoactivity of *Coleus* is debated.
   Another popular plant, a perennial, is the morning glory *Rivea corymbosa*, whose seeds contain lysergic acid amides. Also known as ololiuhqui. In Oaxaca, Mazatec shamans refer to the seeds as "Semillas de la Virgen" (seeds of the Virgin). 50 to 300 ground seeds are soaked in cold water for 1 to 3 days and the filtered liquid is consumed in the evening. However, María Sabina had never used these seeds in any of her ceremonies.

Chapter 6. Albert Hofmann and the Synthesis of Psilocybine and Psilocine

Albert Hofmann became interested in the Mexican relatives of LSD late in 1956, having read about them in a daily newspaper which had piqued his curiosity. However, the newspaper article offered no information as to where the mushrooms might be obtained, so Hofmann had to wait two years before the sacred mushroom would come to him. It was because of Hofmann's research with LSD that the mushrooms finally found their way into his laboratory, where he was able to quickly isolate their active principles.

Fig. 9. Albert Hofmann and Geoffrey Brooke
Amsterdam, Psychoactivity, 1999

In 1958, in a spotless laboratory at the Swiss pharmaceutical firm of Sandoz in Basel, this trim 52-year-old research chemist, at the time the Director of Natural Products, performed an unusual experiment. Hofmann had succeeded in isolating and synthesizing two alkaloids first extracted from dried specimens of *Psilocybe mexicana* Heim. The mushrooms had been grown in vitro in Paris by the eminent French mycologist Roger Heim (Hofmann, 1958 [34]; Unsigned, 1959 [131]). For two years, Heim had sought unsuccessfully to isolate the active ingredients from the mushrooms. Aware of Hofmann's discovery of LSD, Heim had mailed some 100g of dried *Psilocybe mexicana* to Hofmann. Hofmann and his colleagues, after exhausting this supply of mushrooms, grew their own cultures of *Psilocybe mexicana* and other species.

At first Hofmann and co-workers tried to isolate the active principles of the mushrooms using animal bioassays (mice and dogs), which proved unsuccessful. These experiments were inconclusive inasmuch as the animals were unable to describe the effects the mushrooms, which were not evident to observers. Hofmann had exhausted the bulk of the mushrooms sent to him by Heim, and decided to ingest some of the remaining mushrooms to verify that they were indeed active. Albert Hofmann, the "Father of LSD", thus proceeded to eat 32 dried specimens (2.4 g.) of *Psilocybe mexicana* which, according to published reports by Wasson and Heim, was roughly equivalent to an average dose used by shamans in México during their curing ceremonies.

Albert Hofmann and Jochen Gartz in Rovereto, Italy, April, 1992

Hofmann had decided to ingest the mushrooms himself since he could not ask his colleagues to consume them until he had first tried them himself. Hofmann later wrote that the 2.4 grams of dried *Psilocybe mexicana* represented a potent dose by Indian standards. According to Hofmann (1980)[38], "Thirty minutes after my taking the mushrooms, the exterior world began to undergo a strange transformation. Everything assumed a Mexican character. As I was perfectly well aware that my knowledge of the Mexican origin of the mushroom would lead me to imagine only Mexican scenery, I tried deliberately to look on my environment as I knew it normally. But all voluntary efforts to look at things in their customary forms and colors proved ineffective. Whether my eyes were closed or open, I saw only Mexican motifs and colors. When the doctor supervising the experiment bent over to check my blood pressure, he was transformed into an Aztec priest and I would not have been astonished if he had drawn an Obsidian knife." Hofmann also described some of the psychoptic effects, noting: "At the peak of the intoxication, about 1 1/2 hours after ingestion of the mushrooms, the rush of interior pictures, mostly abstract motifs rapidly changing in shape and color, reached such an alarming degree that I feared that I would be torn into this whirlpool of form and color and would dissolve." When the experiment had concluded, Hofmann was happy to have returned home from a very strange and fantastic world. Hofmann then related his mushroom experience to his colleagues, who were later also to ingest them. For subsequent studies, Hofmann and his colleagues used themselves as bioassay, which led quickly to isolation of the active principles, which were subsequently synthesized.

In March of 1958 they published their findings in Experientia. Eight months later, in November of 1958, Drs. A. J. Frey, H. Ott, T. Petrzilka and F. Trozler, all colleagues of Albert Hofmann, then published the chemical structures of psilocybine and psilocine.

The 16 June 1958 issue of Time magazine, reporting on Hofmann's synthesis of psilocybine and psilocine, wrote that he had dissolved five milligrams of pure-white crystals in a test-tube with water and while his colleagues and assistants looked on, had swallowed the potion, lain-down on a couch and waited. Hofmann reported "I am losing my normal bodily sensations... My perception of space and time is changing. ... Your faces appear strange..." and finally, "Now as I close my eyes, I see a wonderful but indistinct kaleidoscopic train of visions. They are vividly colored."

This account of June 16th, 1958, brings confusion to the actual dates of these experiments and is quite different from Hofmann's first reported experience with the 32 dried specimens in which he described himself as being in a partial paranoid- like state. This report of the crystallized chemical intoxication was published between the March, 1958 and November, 1958 issues of *Experientia* as mentioned above. Hofmann soon discovered that the effects from the mushrooms were similar to the effects he had earlier experienced from ingestion of LSD and speculated that both worked on the same part of the brain.

Amsterdam, Psychoactivity, 1998

Hofmann reported that the mushroomic alkaloids were related to the natural neurotransmitter serotonine (5-hydroxytryptamine) and that their chemical structure was likewise similar to that of LSD. Hofmann and his colleagues named the substances in the Mexican mushrooms psilocybine and psilocine. The former given the pharmaceutical trade-name as "indocybin (Registered trademark)" in recognition of the Indians who first used the mushrooms. Indo both for the Indians and for indole, the nucleus in the chemical structure of psilocybine; and -cybin after Psilocybe. Sandoz then manufactured pills with 2 and 5 milligram doses of Indolcybin (Registered Trademark).

Three years later (Hofmann, 1980)[38], Hofmann and his wife Anita accompanied Gordon Wasson on an expedition to the Sierra Mazateca where they were received most graciously by the now-famous curandera Doña María Sabina. Wasson, Albert and Anita Hofmann attended a *velada* and all requested a potion made from the leaves of *Salvia divinorum*, which gave an experience similar to that of the entheogenic mushrooms, although the duration of the leaves effects were shorter - two-three hours as compared to four-six hours for the mushrooms.

During the *velada*, Doña María Sabina did not consume the *Salvia divinorum* but rather partook of Hofmann's Indocybin pills which he later presented to her as a gift. "She was obviously impressed when it was explained to her that we had managed to confine the spirit of the mushrooms in pills." (Hofmann, 1980)[38] María Sabina reportedly consumed 6 of the 5 milligram pills. In the morning she thanked Hofmann for the pills and added that there was no difference between the effects of the pills and the mushrooms, which quite amazed her. She was happy that now she would be able to perform her ceremonies when the mushrooms were out of season. Much later, however, she said she had not really appreciated that the foreigners had taken the power from the mushrooms and recreated it in a laboratory in the form of pills.

Hofmann and colleagues also synthesized various homologues and analogues of psilocybine (CZ-74, CMY-16, and CY19) and psilocine (CY-39 and CX-59), which were also made available for research by Sandoz and later the National Institute of Mental Health (Baer, 1979)[7].

Albert Hofmann also became a collaborator and close friend of Richard Evans Schultes. Over the years they gave lectures at various conferences on entheogenic plants and also wrote two books describing their studies of entheogens (Schultes & Hofmann, 1973 [111]; Schultes & Hofmann, 1979 [112]).

Chapter 7. Mushrooms and Timothy Francis Leary

According to Timothy Francis Leary, he was allegedly conceived on a military reservation known as West Point in 1920. His father Timothy (Tote) was a military man with a penchant for distilled alcohol and his mother Abigail was considered to be the most beautiful woman on post.

After an exciting non-conformist childhood, in August of 1940, Tim, as his father had done before him, entered West Point - a mistake if there ever was one. Because of Tim's shenanigans (drinking and covering up his actions), he was court-martialed and in two minutes of judgment Tim was acquitted. However, his sentence was total silence by his fellow cadets, a silence which lasted for more than seven months. During this period, Tim was constantly harassed and by August of 1941 he had decided to resign his commission from West Point (Leary, 1983)[61].

John W. Allen and Timothy Leary
Photograph by Ron Piper

Fig. 12. John W. Allen and Timothy Leary
Psychedelic Symposium, 1994

In August of 1941, Tim began his study of human behavior at the University of Alabama with psychology as his major, yet by the fall of 1942, Tim was expelled for sexual misconduct and because of his expulsion he lost his draft deferment. In January 1943, Tim reported for basic training at Fort Eustis, Virginia where he was trained in anti-aircraft artillery. After basic training, Tim was selected for Officer's training and before too long Tim was promoted to corporal and assigned to the Acoustic Clinic as a clinical psychologist. After five years in the military, Tim and his new wife Marianne moved west and in 1946, Tim finally received his master's degree in psychology from Washington State University. His thesis was a statistical study of the dimensions of intelligence. In September, Tim was accepted as a doctoral student in psychology at Berkeley. It was at Berkeley where Tim began to foster his ideas on existentialism.

By 1959, Tim had become somewhat successful yet was sufficiently broke. He was the author of numerous scientific papers and two well-regarded books on the diagnosis of personality and had just finished typing a manuscript on new humanist methods for behavior change which he called *Existential Transaction*. Tim was living in a penthouse in Florence, Italy when he was visited by an old drinking buddy from Berkeley, a creativity researcher named Frank Baron. It was Frank who first told Timothy of the Sacred Mexican Magic Mushrooms. Frank even told Timothy that he had brought a bag of the sacred mushrooms back to Harvard. Timothy balked at the idea of the mushrooms and suggested to his friend about the possibility of losing his credibility if he babbled this information to any of his other colleagues. It was Frank Baron who set up an appointment for Tim with David McClelland, Director of the Harvard Center for Personality Research. McClelland was interested in Tim's ideas of existentialism, saying to Tim that "You're just what we need to shake things up at Harvard."

In the summer of 1960 (August), Timothy Leary began his lectureship at Harvard University. This began yet another colorful and exciting chapter in the history of the divine and sacred mushroom. Leary had read R. Gordon Wasson's amazing account recalling his rediscovery of "mushrooms that caused strange visions." This Life magazine article had apparently generated Leary's interest enough so that he wished he could someday experience the effects of the Mexican "magic mushrooms".

Because of Leary's interest in the sacred mushrooms as an adjacent to psychotherapy, clinical applications were soon brought to the academic scene and psilocybin became a new therapeutic tool in psychiatric medicine. This course would soon lead to the widespread recreational use of other drugs such as LSD, mescaline and marijuana, all of which were readily available to students, especially undergraduates, at Harvard University. Such use became pandemic, soon leading to mass civil disobedience in many large metropolitan cities throughout America. All of a sudden, millions of citizens throughout the United States started to take drugs. Eventually, interest and use of psychedelic drugs spread to other countries throughout the world.

While the use of these substances caused no mental or physical problems among those in academic circles where users reported that they experienced euphoria, insight and an awareness of God, there were many new unguided "trippers" who experienced severe dysphoria - resulting in what became known as a "bum trip" or "bad trip". It was because of the "bad trips" resulting from the frivolous use of LSD which eventually led to the prohibited use of these substances by mainstream society's law-making legislature. The death of TV host Art Linkletter's daughter who jumped from a window while high on LSD led the country into a mass hysteria, and many states as well as the Federal Government soon passed legislature banning the use, manufacture and sales of LSD and many other natural entheogenic plant substances. Years later Art Linkletter changed his attitude about many drugs and even felt that marijuana should be legalized.

> **"Timothy Francis Leary holds the honor as the man most responsible for the creation of a new era by which mankind used psychoactive substances in search of neo-religious ideologies through the consumption of certain psychotropic herbs/plants."**
>
> J. W. Allen, "Mushroom Pioneers" (2002)

Timothy Francis Leary holds the honor as the man most responsible for the creation of a new era by which mankind used psychoactive substances in search of neo-religious ideologies through the consumption of certain psychotropic herbs/plants. The use of these magical herbs by individuals who were interested in seeking god caused much confusion and disillusionment in the world. It offered many individuals an alternative lifestyle, one which had not existed for perhaps a millennium.

Because of a few individual dysphoric reactions which occurred in individuals who had ingestion psychoactive drugs, many new laws were created and voted upon, mostly out of fear by legislators who enacted new and harsh drug laws in ignorance - laws which would specifically curb the illicit use of drugs among common citizens of America. This occurred quite hastily in order to pacify the law-enforcement agents who had no real knowledge of drugs. This might cause one to ask, "How can a just society create unjust laws that make criminals out of its citizens?"

These unjust laws eventually brought forth a new breed of American citizens, young and old alike, from all walks of life, including law-enforcement officials. These laws also brought forth an unreal form of civil disobedience, where millions of citizens decided that they were not afraid of being arrested and sent to prison just because they felt that they were within god's right to smoke a joint, eat peyote or consume a sacred mushroom, or any of the other drugs/plants which society deemed to be unacceptable.

Nowhere in any other society or culture in the history of the world have millions of people so blatantly disobeyed the law with such ill-respect as in regards to the drug laws of America. If one is caught breaking these sanctions then that person is liable to prosecution and may be punished for his or her beliefs. Many casual users of entheogenic drugs/plants believe that the plants let them achieve a oneness with god. It must never be forgotten that, when Wasson (1957)[140], Schultes (1978)[106], Leary (1968)[59], and Weil (1980)[138] first experienced the majesty of spirit communion with mushrooms, many of the natural drug-plants were not illegal and that their initial exposure caused a reaction which brought unto them a symbiotic relationship with the magical plant and the true meaning of life. We must never forget that many different species of entheogenic plants were not illegal until the late 1960's and their existence was shared only by an elitist academic segment of society, who for many decades had kept their knowledge sacred and only shared it with their close friends or colleagues.

Under discussion are some of the factors which led to the popularization of hallucinogenic drugs, mushrooms included. The first clue regarding this domino effect, common among those people who have formed a sacred communion with entheogenic healing plants, comes from word of mouth among friends, the public press, drug sub-culture publications, television and Timothy Leary - who was the first person to bring the mushrooms, their effects and their benefits to the attention of the academic public.

While Wasson and his colleagues introduced us into the fascinating world of the "magic mushrooms," it was Leary who introduced us into the "psychedelic" age. He shared his special knowledge with the world. What else could he do once the mushrooms had spoken to him? "Tune in, turn on, drop out" found meaning with many. It became the creed of a whole generation. Imagine that, the beneficial and euphoric rewards of "mind-tripping" into the subconscious, what a trip. Fantastic journeys through the mind. By the early 1970's, President Richard Milhous Nixon had referred to Timothy Leary as "the most dangerous man in the world."

Leary's First Voyage

Prior to the "hippie" and "bohemian" invasion into Mexico during the 1960's by thousands of individuals seeking out the sacred mushrooms, Timothy Francis Leary, still a young Harvard psychologist, was spending his summer vacation in a quiet villa near the tiny village hamlet of Cuernavaca, Mexico. It was at Leary's rented villa resort swimming pool, while relaxing under the hot Mexican sun, that Timothy Leary consumed his first "magic mushrooms."

Leary was waiting for Gerhardt Braun, an anthropologist-historian-linguist from the University of Mexico. Braun was a frequent visitor to Leary's villa, and he had read of the mushrooms while translating ancient Aztec *Nahuatl* texts. His growing interest had aroused something within him, definitely causing him to want to experience the wondrous mushrooms. After a short period of time Braun learned that the so-called "magic mushrooms" could be found growing on the volcanic slopes of Toluca near the village hamlet of San Pedro.

However, it was on the streets of San Pedro, under an arch in the local market, that Gerhardt Braun finally purchased a bag of "magic mushrooms" which he had obtained from an elderly sun-baked Señora named "Old Juana." So, Braun, very excited, then called Leary at the villa in Cuernavaca to inform him that at last he had finally purchased some "magic mushrooms." Leary had first heard of the mushrooms from his friend and colleague Frank Baron. In Baron's own words, "And so I commended the mushroom to the attention of a colleague of mine at Harvard University, Dr. Timothy Leary, who was an active practitioner of group therapy. He [Leary] became interested in its possibilities as a vehicle for inducing change in behavior as a result of the altered state of consciousness that the drug produces (Baron, 1963)[8]." Thus began the "psychedelic age" as Leary and several of his friends would participate in their first communion with the sacred mushrooms of Mexico.

As Leary consumed the fungi (seven mushrooms, *Psilocybe caerulescens* Murr.), he complained of their somewhat bitter and acrid taste with no impending comprehension as to what was about to happen to him. He never thought for one minute that it would forever change the course of his life.

Fig. 13. Tim Leary Psychedelic Symposium Chapman University, 1994

Leary (1968)[59] later claimed that "It was the classic visionary voyage and I came back a changed man. You are never the same after you've had that one flash glimpse down the cellular time tunnel. You are never the same after you've had the veil drawn." Later, Leary returned to the market place where the mushrooms were purchased from Crazy Juana but he was unable to find her or anyone who might be able to provide him with more specimens of the fungi.

> **"You are never the same after you've had that one flash glimpse down the cellular time tunnel. You are never the same after you've had the veil drawn."**
>
> Timothy Leary, "High Priest" (1968)

Later, Leary's friend and colleague Richard (Baba Ram Dass) Alpert, also from Harvard, had flown down to Mexico and offered Leary a ride back to Massachusetts. Leary decided to share with his friend some comments concerning his mushroom experience by describing to Alpert his most recent ecstatic and religious experience while under the influence of the metaphoric fungi. Leary claimed that "I was whirled through an experience which could be described in many extravagant metaphors but which above all and without question was the deepest [most] religious experience of my life" (Leary, 1968 [59], 1983 [61]).

Alpert's response to Leary's experience came as a shock, since neither person had attained much knowledge in the field of psychoactive drugs. However, Alpert was familiar with the "tea" scene (the use of marijuana and hashish) and related to Leary his impression of the drug marijuana by mentioning that there were cults of beatniks and Bohemians in San Francisco who used hashish and marijuana in dark corners of jazz houses and other nightclubs. They did this in secret out of fear of being arrested for their illicit activities. Alpert even went on to refer to this practice as "cultic." At the time of this conversation, very little research had been conducted involving humans and psychedelic drugs. These comments by Leary and Alpert in the fall of 1960 appeared to be their only knowledge of drugs and drug use. This occurred approximately two to two and a half years before Leary had consumed his first tablet of Sandoz LSD. Of course, it should be mentioned that there were numerous sessions of drug therapy being conducted at Harvard where researchers in a controlled environment gave LSD, mescaline, marijuana, hashish and DMT to student volunteers.

For several years after Leary first consumed the sacred mushrooms in Cuernavaca, he had been offered LSD but was afraid to experiment with it (Metzner, 1970)[75]. The mushroom trip which Leary had experienced would soon trigger a series of events during the next few years, events which would lead to the massive popularization of many mind-altering drug/plants. Leary eventually came to prosthelytize the use of mind-altering chemicals and his advocacy of these drugs played a central role in their re-emergence into western civilization. The use of these drugs was like a religious revival, a revival of people from all walks of life, who would soon become willing pawns in the psychedelization of mind-altering drug/plants. These innocent pawns would soon began to experiment with many varieties of entheogenic drug/plants and use them as sacraments and as a new form or type of recreation. Leary's eminent concern of course would be to use these substances as adjacents to psychotherapy. Soon research grants were sought and applied for and eventually approved. Leary soon began to conduct laboratory experiments with human subjects in controlled environments, all within the framework of the law. It should be mentioned that when Leary conducted this research, most, if not all of the drugs he utilized, were legal at the time, possibly with the exception of peyote (mescaline) and marijuana.

The Harvard Psilocybin Project and Marsh Chapel

Leary's first experiments using what became known as psychedelic drugs involved prisoners at the Concord Massachusetts Reformatory for Men. At first, Leary earned public acclamation among his peers and colleagues at Harvard by opening the door into a new and somewhat mystical dimension and an unusual approach to psycho-therapeutic research.

A new adventure and chapter into the often mysterious subconscious mind of man was about to formulate into existence, a concept in therapy that would shake the very foundation of an established Christian-orientated society. A society which would not condone mankind's intellectual use of mind-altering drugs as a way of life.

One of the most important factors which evolved from Leary's research with psychoactive substances was that Leary created an atmosphere where, because of him, millions of individuals began to use hallucinogenic drugs for purposes other than spirituality, healing or divination. However, who is to say that one's experience under the influence of such drugs is not of a religious nature? This frivolous use of mind-altering drugs created an overall negative attitude amongst the ruling class and legislative branches of the government. They were apparently afraid that these drug/plants would enable users to expand their natural minds into a more flexible opened mind and a new way of thinking - a way of thinking which was definitely not adherent within society's moral turpitude and Christian way of living.

Leary also began to turn friends on to these mushrooms and felt that theses sacred mushrooms should only be used by gifted people. Allen Ginsburg ate mushrooms at Leary's home in Millbrook, took off all his clothes and then ran naked from Leary's home.

He was not to be seen for more that a few months. Leary also turned on many other gifted people to the mushrooms during the early and middle 1960's (Koestler, 1960)[49].

Leary first began his program of therapeutic mushroom use by placing an order with Sandoz Pharmaceuticals in Basil, Switzerland, for the mushroom pills known as "indocybin". Leary had no comprehension that his work with hallucinogenic drugs as an adjacent to psycho-therapy would ever become as popular as it did.

On the day Leary received his first batch of "indocybin" pills, he was at his home in MillBrook and his friends soon encouraged him to return to his office at Harvard to retrieve the pills. Leary and his friends had decided that if they were to attempt to use these pills on human subjects then maybe they should try them first. Before the night was over, Leary and several of his friends had somehow managed to consume the entire vial (100/ 2 mg. pills) of "indocybin". This caused Leary to then re-order another vial of the mushroom pills. It took several weeks for the pills to arrive, giving Leary enough time to prepare his group of researchers to begin implementation of his program. Leary, like María Sabina, also believed that the mushroom pills were no different in effect than the actual mushrooms which he had consumed while vacationing in Mexico (Leary, 1968)[59].

During 1961 (Leary, Litwin & Metzner, 1963 [65]; Leary, 1968 [59]), and the following academic year, Leary and Jonathan Clark worked an intensive tightly structured program involving several small groups comprised of inmates from the Concord Massachusetts State Reformatory for Men. The experiments conducted by Leary and his colleagues on prisoners in this institution gave the psychopharmacologists a new insight into each prisoner's mind and life (Leary, 1961e) [57].

One of the primary goals set in the Harvard psilocybin research projects which used LSD, mescaline and psilocybin as an adjacent to psycho-therapy, was to set goals for the prisoners so that upon their release from prison they would be better able to adjust their lives - both physiologically and psychologically - back into society.

Another goal was to help the prisoners by changing their aggressive thinking disorders which originally caused them to be put in prison. It would appear that the ultimate goal of Leary and his associates would be to change these unhappy thinking anti-social individual souls into happy peaceful loving citizens who, upon release from prison, would end up becoming more productive members of society.

The end results of these early experiments using human subjects were quite satisfactory, but inconclusive as far as prison officials were concerned. The program was abruptly halted because of the adverse publicity which surrounded Leary and his use of consciousness-expanding drugs on human volunteers. Thirty-four-years later, follow-up studies to Tim's experiments at Concord were conducted and the results published (Doblin, 1999-2000 [15]; Leary, 1963 [58]; Leary, 1969 [60]; Leary & Metzner, 1968 [63]; Metzner, 1999-2000 [76]; Metzner & Weil, 1963 [77]; Riedlinger & Leary, 1994 [92]).

Another interesting aspect to Leary's approach to psychoactive substances occurred when Leary administered psilocybin pills to a pregnant woman. Leary provided this subject with psilocybin every two weeks during the woman's pregnancy until her delivery. Leary continued to do follow-up research on the woman for about one year after the child was born. Both the woman and child suffered no ill effects from the consumption of the mushroom pills. The mother did experience some nausea with vomiting while under the influence of the mushroom pills, but no other uncomfortable, unpleasant, or undesirable effects were noticeable or reported during the experience (Leary, Litwin & Metzner, 1963)[65]. Other studies by JWA in 1976-1977 (unpublished notes) indicate that severe nausea does occur from the consumption of psilocybin-containing mushrooms if taken during pregnancy and if taken with alcohol. Furthermore, no one should ever, under any set of circumstances, take any drugs when pregnant unless prescribed by a physician.

Another well-publicized experiment occurred in a University Chapel in Boston on the evening of Good Friday 1962. It was here that twenty theology students took part in Walter Pahnke's Psilocybin experiments. Ten students were given 30 mg. of psilocybin and ten others were given 200 mg. of nicotinic acid, laced with a small amount of Benzedrine to stimulate the initial physical sensations attributed to a psychedelic experience.

This experiment became know as "The Miracle of Marsh Chapel". During the following six months after this experiment, researchers collected extensive data which included tape recordings, group discussions, follow-up interviews and a 147 - item questionnaire used in quantifying the characteristics of a psychedelic experience (Stevens, 1987c [126], d [127]; Leary, 1961c [55], 1961d [56]; Koestler,1961 [41]; Roberts & Jesse, 1998 [96]).

Eventually, Tim was fired from Harvard for failure to attend his lectures. Interestingly, it was partially the fault of Harvard Crimson reporter Andrew Weil that brought Tim Leary his walking papers. Weil had been reporting on Tim's extra-curricular activities involving the giving of drugs to undergraduates which resulted in the firing of both Tim and his friend and colleague Richard (Baba Ram Dass) Alpert (Unsigned, 1963a [133], 1963b [134]).

Years later, John Lennon and Yoko Ono wrote Tim that they had written a song during their Toronto bed-in in Tim's honor. The song: "Come Together".

In June of 1996, Tim Leary passed away and in March of 1997, one gram of Timothy Leary's cremated ashes, along with the ashes of "Star Trek's" Gene Roddenberry and 23 others, was launched into space via a satellite and is now part of the universe.

As a final word regarding some of the early research involved with hallucinogenic mushrooms, the author remembers hearing a story which circulated during the early 1970's which indicated that Sandoz laboratories in Mexico allegedly received a grant to study psilocybin.

They were supposed to manufacture a headache tablet to replace aspirin. According to this story, Sandoz could not produce a pill for headaches because they could not separate the visuals from the tranquil effects of the mushroom experience. It should be noted that this story has not been verified by the author. However, it would appear that if Sandoz had conducted such investigations, they could have made a mild pill which would have produced mild tranquillity in patients rather then a hallucinogenic visual experience.

Chapter 8. Biographies of Other Mushroom Pioneers

Below are several dozen short biographies of some of those psilophorians whose interest in the sacred mushrooms goes far beyond that of their own minds.

Arno Adelaars - graduated from the University of Amsterdam, is a Dutch freelance journalist and has published a fine book on European psilocybian mushrooms, "*Alles Over Paddo*'s". Adelaars, together with Hans van den Hurk and Claudia Müller-Ebeling, were the organizers of the October 1998 "Psychoactivity" conference at the Tropen Museum in Amsterdam.

Michael Aldrich - is curator of the Fitz Hugh Ludlow Memorial Library and author of "*The Dope Chronicles 1850-1950*". Mr. Aldrich presides over the largest collection ever assembled of drug-related material from all over the world.

John Marc Allegro - was a British theologian and expert in ancient and archaic languages of Asia Minor (1925-1988). During the 1950s, Allegro was a colleague of the international team of scientists assigned to decipher and translate the Dead Sea Scrolls and was therefore made an Honorary Adviser by King Hussein of Jordan. The publication of his brilliantly written basic study on the fly agaric as a possible origin of early Christian belief systems (*The Sacred Mushroom and the Cross*, 1970) gave him worldwide recognition, but led also to furious hostilities by orthodox theologians, who reacted angrily at the thought provoking title of his book and not justly recognizing the value of the scientific records which Allegro had formulated within the book.

John W. Allen - is an amateur ethnomycologist living in North America. Mr. Allen is the author of ten books (including *Magic Mushrooms of the Pacific Northwest* (1976-1997) the oldest selling identification guide on entheogenic mushroom identification) and more than two dozen articles on the subject of visionary mushrooms and the editor and author of the series *Ethnomycological Journals Sacred Mushroom Studies*. Additionally, Mr. Allen has photographed mushrooms in America, Hawai'i, Southeast Asia, Great Britain and Europe.
Furthermore, Mr. Allen is the discoverer of a new entheogenic mushroom species from Thailand, named *Psilocybe samuiensis* Guzmán, Bandala and Allen. Since the late 1980's Allen has lectured at conferences and symposia, given many slide-show presentations on the history and identification of entheogenic mushrooms and mushroom art throughout the ages at various universities world-wide. His current works include the new CD-ROM, Volume V of *Ethnomycological Journals Sacred Mushroom Studies*, *Psilocybian Mushroom Cultivation: A Brief History* co-authored with Jochen Gartz, Volume VII: Mushroom Pioneers (February 2002) and a forthcoming bibliography of psilocybian and other species of Entheogenic Fungi also co-authored by Dr. Jochen Gartz of the University of Leipzig, Germany.

Richard Alpert - also known as Baba Ram Dass, was Timothy Leary's colleague. He has worked extensively in the field of transcendental meditation, yoga and other eastern philosophies. Alpert, along with Leary, obtained a supply of synthetic psilocybine from Sandoz for use in experiments on prisoners at the Concord State Prison in Massachusetts.

James Arthur - (1958-2005) was deeply involved in studying mushrooms and religion. He was an author, lecturer, and performer who argued that A. muscaria and psilocybian mushrooms were very influential in Christianity and other religions. Arthur explored the idea that Religions have become entities far removed from their original intention as helpers of mankind and have, through ego-inspired misinterpretation of revelation and/or simple control motivation, becomes oppressive to mankind. His views were controversial and disputed by other authors in the field. Arthur also spoke publicly about other topics such as UFOs.

Wolfgang Bauer - is a German psychologist who has studied extensively on optical illusions by Prof. Rausch at the J.W. Goethe - Universität in Frankfurt/Main. Bauer is also editor of Sergius Golowin's classic treatise on witches herbs and magic mushrooms (*Magie der verbotenen Märchen*, Hamburg, 1973), which became a cult-book in the Seventies and which was secretly xerox-copied in the then communistic eastern part of Germany and later redistributed in the hippie-underground there. Furthermore, Bauer is co-editor of *Integration - Journal for Mind-Moving Plants and Culture* and also editor and co-author of *Der Fliegenpilz - Traumkult, Märchenzauber, Mythenrausch* (Aarau 2000). His collection of objects relating to the fly-agaric has been exhibited by the Karl Ernst Osthaus-Museum (Hagen) several times throughout many European Museums.

Michael Beug - was Academic Dean at Evergreen State College in Olympia, Washington. Beug has taught mushroom identification at Evergreen and at mushroom conferences throughout the U.S.A. since 1972. He is also a contributor of photographs to more than a dozen books, and has published numerous scientific papers on mushroom toxins and mushroom- identification keys.

Frank Barron - was a colleague of Timothy Leary, who first told Leary that he had brought some mushrooms he had obtained in México back to Harvard. This was the first Leary had heard of their special power, and later inspired Leary to ingest these special mushrooms.

Antonio Bianchi - is an Italian anesthesiologist and toxicologist, and is an expert on visionary mescaline-containing cacti from Perú (San Pedro) and México (péyote). Bianchi has also studied the soma mushroom, *Amanita muscaria*.

Jeremy Bigwood - is a biochemist and mushroom cultivator. In the late 1970's Bigwood was a co-ordinator of the Second International Conference on Hallucinogenic Mushrooms, where he lectured on new and improved methods for the cultivation of *Psilocybe cubensis*. Bigwood was also co-editor with Jonathan Ott and contributor to *Teonanacatl: Hallucinogenic Mushrooms of North America*. He attended Evergreen State College in Washington State where he collaborated both with Michael Beug and Jonathan Ott. Bigwood and Michael Beug contributed two scientific articles to the Journal of Ethnopharmacology on potency levels of in vitro grown specimens of P. cubensis and other psilocybian mushrooms from the Pacific Northwest of the United States. Furthermore, Bigwood and Ott presented one of the first methods for inoculating shrooms spores using syringes.

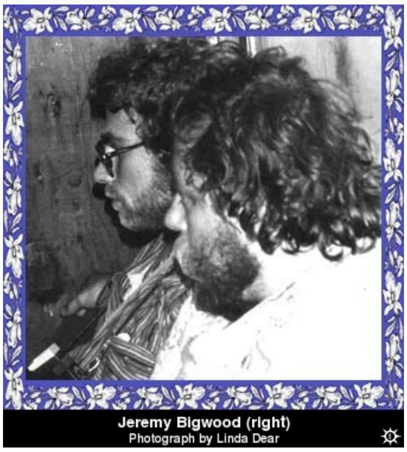

Fig. 15. Jeremy Bigwood (right). Photo: Linda Dear

Richard Glen Boire - is a California attorney who defends clients charged with drug-law violations. He is the publisher of a newsletter The Entheogenic Law Reporter, devoted to drug-related law and news. Boire is also the author of *Sacred Mushrooms and the Law* and *Marijuana Law*.

Masha Wasson Briten - is the adopted daughter of R. Gordon Wasson, who, along with her mother, Valentina Pavlova Wasson, became the first westerner to consume the magic mushrooms outside of a ceremonial context.

J. Christopher Brown - is a graduate student in Botany at the University of Massachusetts who helped to organize the Gordon and Tina Wasson Ethnomycological Collection at the Harvard Botanical Museum.

Carlos Castaneda - is an anthropologist who has written several novels ostensibly about a Yaqui Indian medicine-man named Don Juan. In the what is the first saga, being an account of an alleged relationship with a Yaqui Indian medicine man, *The Teachings of Don Juan: A Yaqui Way of Knowledge*, mentions a smoking-mixture which Don Juan allegedly referred to as humilito.
According to Castaneda, this smoking-mixture contained psilocybian mushrooms ground into a fine powder. This book led many pilgrims to México in search of the "magic mushrooms." It should be noted that no other Yaqui Indians are known to use psilocybian mushrooms, nor have the mushrooms ever been reported to be smoked elsewhere by anyone in México.

Stephan F. de Borhegyi - is an archaeologist who studied the mushroom stones of Middle America and published a few papers regarding them.

Jim de Korne - is the author of *Psychedelic Shamanism* and has contributed two chapters in his book on the sacred mushrooms.

Richard de Mille - has exhaustedly studied the Carlos Castaneda controversy in the process shedding doubt on the authenticity of Castaneda's research and his books concerning his relationship with the (to De Mille) non-existent shaman, Don Juan.

Herman de Vries - is a Dutch artist who is also editor-in-chief of *Integration - Journal of Mind Moving Plants and Culture*. De Vries, spent most of his life suffering from asthma. Doctors told him that he would not lived beyond fifty years of age. However, on the 17th of January 1970, De Vries said goodbye to his illness after an LSD-experience which forever changed his life. And since that very day he has been in the best of health. De Vries believes that as a humans we all have an existential basic right to test and experience all the possibilities which nature offers us. As an artist, De Vries has participated in almost 500 exhibitions and his works are represented in 48 museums.

Rick Doblin - is the founder and current president of *MAPS* (Multidisciplinary Association for Psychedelic Studies) and has recently conducted a follow-up study to Timothy Leary's, Concord Psilocybin Prison Project. Rick is currently in the Ph.D. program in Public Policy at Harvard's Kennedy School of Government and has previously graduated from Stan and Christina Grof's Holotropic Breathwork 3-year training program.

Wendy Doniger O'Flaherty - was co-author with R. Gordon Wasson of *Soma: Divine Mushroom of Immortality*, and is an expert on the Hindu epic *Reg Veda*, also having edited an anthology with some of the original text.

William Emboden - is Professor of Biology at the University of California at Northridge and author of *Narcotic Plants*, an excellent book on visionary and other psychoactive plants. A section of this fine book is devoted to mushrooms.

Leonard Enos - is author of the first identification manual for psilocybine-containing mushrooms common in the Pacific Northwest United States. Mr. Enos' "*A Key to the North American Psilocybin Mushroom*" is poorly written, illustrated with imaginative water-colors of the common species, and tells the prospective collector where, when and how to find several species of psilocybian mushrooms. There is also a un-practical chapter on cultivation of psilocybian mushrooms and another chapter on a so-called philosophy involving psilocybin mushrooms.

Alvaro Estrada - is a Mazatec Indian who speaks and writes Spanish. His interviews with María Sabina were the basis for her autobiography *Vida de María Sabina: La Sabia de Hongos*, translated into French as "*Autobiographie de María Sabina: La Sage aux Champignons Sacrés*"; English as "*María Sabina: Her Life, Her Chants*"; into Portuguese as "*A Vida de María Sabina, a Sabia dos Cogumelos*"; and in German as "*María Sabina: Botin der Heiligen Pilze*".

Michael Fehr - is director of the Karl Ernst Osthaus-Museum in Hagen (Germany). Fehr has organized several exhibitions on the studies and use of the fly-agaric mushroom *Amanita muscaria*. One article of importance to this work has Dr. Fehr discussing the role of psychoactive fungi as objects of museum didactic considerations published in *Der Fliegenpilz* - ein kulturhistorisches Museum (Köln, 1991), a book, of which Michael Fehr is also the editor.

Francisco Festi - is a researcher of entheogenic mushrooms and author of *Funghi Allucinogeni: Aspetti Psicofisiologici E Storici* (in Italian, 1985). An excellent book covering both Old and New World histories of usage, chemistry and pharmacology of these interesting mushrooms.

Nat Finkelstein - was just a young student when he traveled to México in the late 1960's. While their he was most fortunate to consume the sacred mushrooms. Finkelstein later wrote of his experience in an article for *Psychedelic Review* "Hongi Meester" relating his personal mushroom velada with María Sabina.

Peter Furst - is Professor Emeritus of Anthropology at the State University of New York at Albany, a member of the American Department of the University Museum at the University of Pennsylvania, and a research associate in ethnobotany at the Botanical Museum of Harvard University. Furst is the author of *Hallucinogens and Culture*; *Flesh of the Gods*; and *Mushrooms: Psychedelic Fungi*. The latter is part of the *Encyclopedia of Psychoactive Drugs* series.

Jochen Gartz - is a biochemist and mycologist at the University of Leipzig, Germany. Gartz is also founder of the Department of Fungal Biotransformation at that University. Gartz has traveled extensively and conducted field-research in Europe, South Africa and the US Pacific Northwest. He has authored more than 50 scientific papers on the chemistry and cultivation of entheogenic mushrooms and has authored field guides (publ. in German and English) for the identification of psilocybian mushrooms. Gartz is the discoverer of a new entheogenic mushroom from Africa, which he named *Psilocybe natalensis*. His books include *Magic Mushrooms Around the World* (1996), an English translation of the two German editions of "*Narrenschwämme*" (1993); and (co-authored two books on CD-ROM with John W. Allen) "*Magic Mushrooms in Some Third World Countries*" (1998) and "*Psilocybian Mushroom Cultivation: A Brief History*" of which the latter is currently being translated into a German edition by Gartz.

Rich Gee - is co-author with Jule Stevens of *How to Grow and Identify Psilocybin Mushrooms* and author of an aquarium guide to the latest techniques for growing psychoactive mushrooms, *Cubensis Aquarium Gardening Workbook Edition*. Mr. Gee is a pioneer in the field of mushroom cultivation.

Ewald Gerhardt - is a European mycologist who has just published a revision of the genus *Panaeolus*.

Hartmut Geerken - is a german writer, musician and paramycologist. As a child Geerken shared a symbiotic relationship with wild edible mushrooms which helped in his survival during the famine after world war II. Increasingly intererested in fungi Geerken eventually became the Editor-in-Chief of *Paramykologische Rundschau* (a paramycological review; 1979 cont.). Geerken also conducted several field studies of Afghan fungi and in the late 1970s along the Afghan-Pakistani border discoverd the up to then unknown "*boletus (tubiporus) pactiae* gee". (s. *Afghanistan Journal*, Graz; 1978/1). Geerken also worked on hallucinogenic mushrooms and mycological folklore healing practises in the middle hindukush and introduced the term rabenbrot to the mycological discussion. In Namibia he did research on the Termitomyces 'omajowa'. Additionally, Geerken has also published numerous books of contemporary literature, directed radio plays and performances and composed musical works in which mushrooms always played an important role. He is also playing the musical works of the mycologist John Cage.

Allen Ginsburg - was one of the first people Timothy Leary introduced to psilocybian mushrooms. According to Leary, Ginsburg, after becoming inebriated by the mushrooms, ripped-off all of his clothes and from Leary's Millbrook estate ran stark naked down the street and was not to be heard from until several months later.

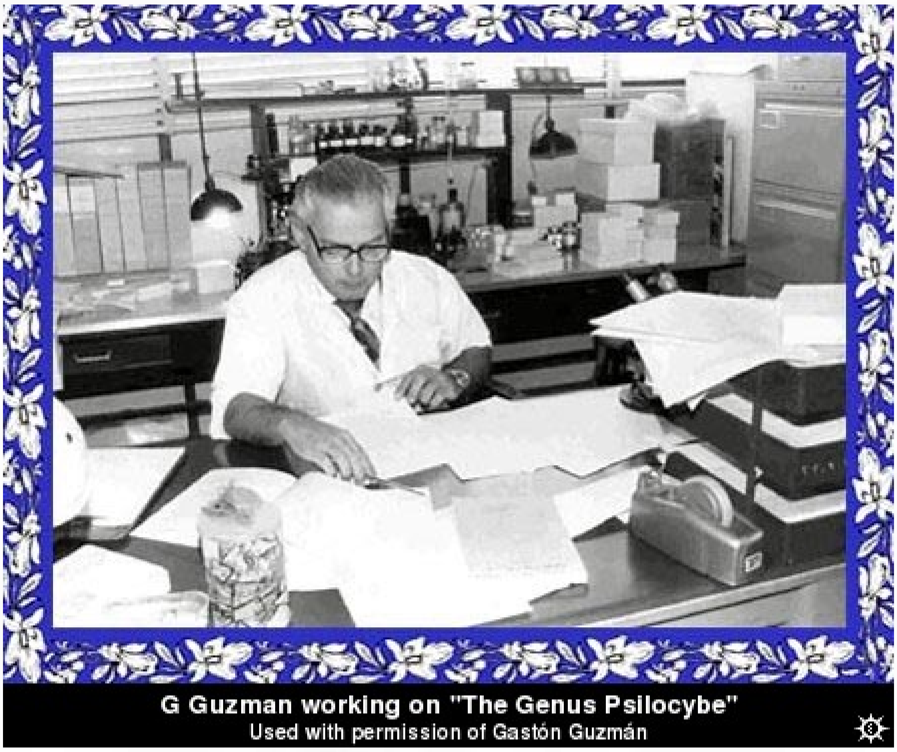
F. F. Ghouled - is author of The Field Guide to Psilocybin Mushrooms. Ghouled, along with colleague Richard Meridith, later published Psilocybin Cultivation after changing his name to F. C. Gould. This former book described collection of *Psilocybe cubensis* found only in the Southeastern United States from Texas to Florida and north to Georgia. Ghouled also alleged *Amanita muscaria* was the famed "magic mushroom" of México [sic!] and mis-identified two photographs of *Psilocybe cubensis* in their young stage of grow as *Panaeolus subbalteatus*.

Sergius Golowin - is a renown Swiss writer and folklorist, who in his book *Die Magie der verbotenen Märchen* (Hamburg, 1973), was the first person to infer that there was a connection between the caps of the dwarfs and other beings in fairy tales and the appearance of the fly agaric, a mushroom which sports a red cap (hat). Golowin is also the founder of the Psychedelic Folklore (Psychedelische Volkskunde) and has made in the early Seventies, a very impressive experiment when he bioassayed seven dried caps of the fly agaric. The account of his experience is printed in *Der Fliegenpilz - Traumkult, Märchenzauber, Mythenrausch*. Furthermore, when Dr. Timothy Leary was arrested in Switzerland after his flight from the U.S.A., Golowin started an initiative intended to get Leary out of Swiss prison and later attempted to help Leary get a residence permit for Leary to remain in Switzerland.

Adam Gottlieb - is author of *The Psilocybin Producer's Guide*, a poorly written book on cultivation with several identification errors which were never corrected in subsequent printings (*Psychedelic Underground Library: Nine Rare Classics*) and reissues of the original book and later the same errors were reprinted in an updated version of his booklet retitled as *Psilocybin Production*.

Robert Graves - was a British author and historian Who wrote also on Greek Mythology and was one of the first persons to whom R. Gordon Wasson gave the sacred-Mexican mushrooms. Graves wrote several articles about mushrooms, including one in which he described his experience while under the influence of psilocybian mushrooms - This article appeared in an issue of *Holiday* magazine (Graves, 1962)[26].

Gastón Guzmán - is a Mexican mycologist, co-founder and past President of the Mexican Mycological Society. Guzmán has spent more than 44 years studying mushrooms, working mainly in taxonomy, ecology and ethnomycology. He presently works at the Instituto de Ecología, Xalapa, Veracruz, México, where he founded the Mycology Department in 1989.



G Guzman working on "The Genus Psilocybe"
Used with permission of Gastón Guzmán

Fig. 18. Gastón Guzmán in his laboratory working on his Monograph *The Genus Psilocybe*

Guzmán has published more than 350 papers on fungi and 8 books. His first book, published in 1977 was the first mushroom field guide published in Mexico. In 1983 Cramer published his monograph on Psilocybe (now out of print): *The Genus Psilocybe: A Systematic Revision of the Known Species Including the History, Distribution and Chemistry of the Hallucinogenic Species*. In 1995 Cramer also published a supplement to that monograph. Guzmán had described more than one hundred new species of Psilocybe throughout the world. His most recent book, published in 1997, is a checklist of Spanish names for mushroom species of Latin American mushrooms, a monumental work covering more than 5,500 common names with scientific equivalents (over 1600 species). Guzmán began his first studies in 1955 and 1957 became field assistant to Rolf Singer, then investigating the hallucinogenic fungi of México. In an obscure village of southern México, Guzmán attended an Indian ceremony where he partook of the visionary mushroom (*Psilocybe cubensis*).

Since 1995 and 1997 Guzmán has been honored as an Emeritus National Research Fellow in Mexico and an Emeritus Research Fellow of his Institution. Guzmán's current work is *A Worldwide Geographical Distribution of the Neurotropic Fungi, Analysis and Discussion*, a listing all of the known psychoactive species (218 and counting) and their worldwide distribution, co authored with John W. Allen and Jochen Gartz. This large monograph will appear in the Italian Journal *Annal des Musei Civici de Rovereto*. Guzmán is considered to be the leading authority on the taxonomy of the Mexican entheogenic mushrooms.

Richard and Karen Haard - were not directly involved in the study of hallucinogenic mushrooms, but they did publish in the mid-1970's one of the first field guides devoted specifically to the identification of both poisonous and hallucinogenic mushrooms of the Pacific Northwest United States. Richard Haard, Ph.D., is a graduate of Kansas State University, and formerly an associate Professor of Biology at Western Washington State College. Haard taught at the Nature Study Institute, Bellingham, Washington, which he and his wife Karen founded in 1974, and also worked as a biological-system consultant for various Indian tribes of North America. Karen Haard, B.Sc. is also a graduate of Kansas State University, and a former research technician in a biological laboratory.

Joan Halifax - is an anthropologist with an interest in shamanism and preliterate cultures that have used drug-plants. She was a close friend of R. Gordon Wasson's.

Martin Hanslmeier - is a German physician and psychotherapist who has been engaged in the study of mycology since childhood. Hanslmeier is also a painter and photographer of psychoactive fungi. His study on German psychoactive mushrooms (Mykographie einer Wiese in der Rhön) has been printed in Herman de Vries' catalogue of a large collection of herbs and plants (Natural relations, Nürnberg 1989). Also numerous articles on magic mushrooms have appeared in many journals and publications throughout Germany.

Bob Harris - is the author of *Growing Wild Mushrooms* and the creator, along with David Tatelman, of the Homestead Mushroom Kit. Harris also invented a wheat-straw pasteurizer to be used in mushroom cultivation.

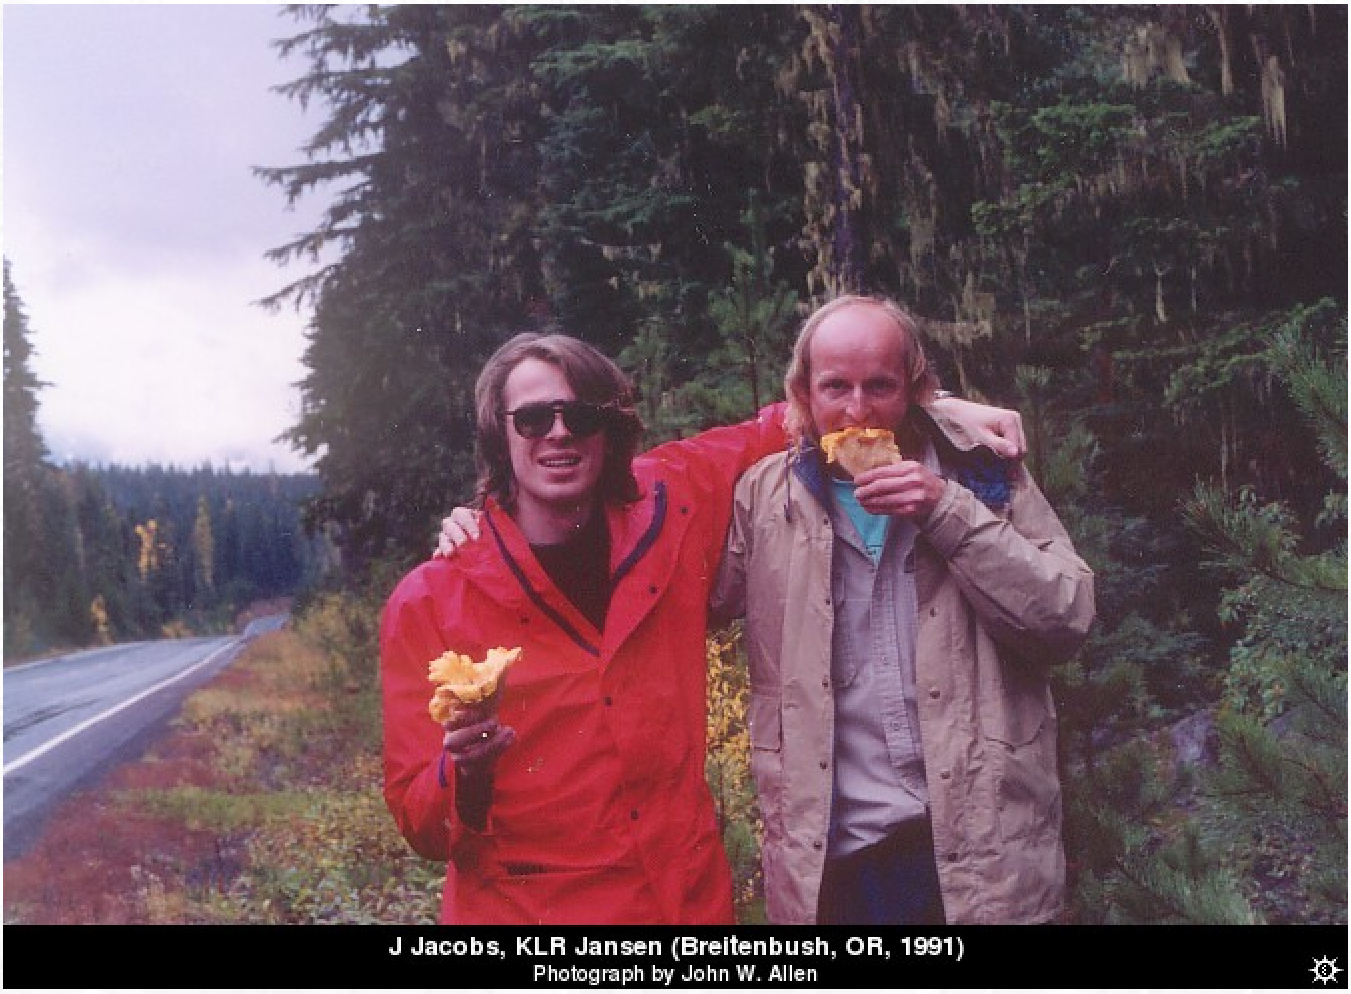
Roger Heim - was the noted French mycologist who accompanied R. Gordon Wasson on several expeditions into the Sierra Madre of México and identified taxonomically the first seven species of hallucinogenic fungi used in traditional healing ceremonies in Oaxaca, México [see Wasson, 1957 [140];Heim & Wasson, 1958 [33]]. Heim contributed amply to scientific journals, including more than fifty articles concerning the sacred mushrooms of México and, together with his colleague Roger Cailleux and many other specialists, was first to cultivate the entheogenic mushrooms.

Margaret Holden - is an English mycologist who reported on the poisoning of a young boy who had allegedly consumed *Panaeolina foenisecii*. Similar intoxications were reported by the Australian physician R. V. Southcott (1974)[119] and by the American mycologist Orson Miller, (1971)[79].

Hans van den Hurk - is the founder of the Conscious Dreams Smart Shop and wholesale operation in Amsterdam, which legally sells fresh psilocybian mushrooms, péyotl and other natural entheogens. Conscious Dreams, which now has five shops in Holland, was the first Smart Shop in Amsterdam and also the first to offer psilocybian mushrooms for sale. Conscious Dreams is renowned throughout Europe. Currently The legality of psilocybian mushrooms in the Netherlands is being challenged by the courts.

Aldous Huxley - spent the last decade of his life in the study of entheogens, after Humphrey Osmond introduced him to mescaline in 1953. Mr. Huxley is the author of *Brave New World* and *Island*, both of which were about drugs and their integration into society.

Jim Jacobs - has done field-work on psychoactive mushrooms throughout México, Canada, and the United States since 1975. His collections were described in the monograph *The Genus Psilocybe* by Gastón Guzmán. Jacobs is a member of the Oregon Mycological Society's Toxicology Committee and is an independent consultant with Oregon's Poison Control Center. Recently a species of *Psilocybe* was named in his honor *Psilocybe jacobii* Guzmán.



J Jacobs, KLR Jansen (Breitenbush, OR, 1991)
Photograph by John W. Allen

Fig. 19. Jim Jacobs and Karl L. R. Jansen
Chantrelle hunting, Breittenbush, Oregon, 1991

Karl L. R. Jansen - is the M. D., Ph. D., is a member of the Royal College of Psychiatrists and is the co-author, together with John W. Allen and Mark D. Merlin, of the paper *An Ethnomycological review of Psychoactive Agarics in Australia and New Zealand*, was published in a 1991 issue of Journal of Psychoactive Drugs. Jansen is also one of the worlds leading experts on ketamine. He has studied ketamine at every level: from photographing the receptors to which ketamine binds in the human brain, to publishing numerous papers on his discovery of the similarities between ketamine's psychoactive effect and the near-death experience. His writings have appeared in over 30 medical journals and popular magazines of our times. Jansen's recent book, *Ketamine: Dreams and Realities*, is a *tour de force*, and the authoritative tome on the subject. Jansen has also published several papers on the Thai narcotic plant known as *kratom* (*Mitragyna speciosa*).

Irmgard Weitlaner Johnson - is a specialist in prehispanic and contemporary Mesoamerican textiles and was one of the first westerners to witness a sacred mushroom ceremony.

Everett Kardel - a pioneer in publishing a successful Indentification manual for Pacific Northwest Psilocybe mushrooms is an Oregon author of an early identification guide for mushrooms of the Pacific Northwest (*Magic Mushrooms*), a unique pamphlet printed on a mimeograph machine.

Keewaydinoquay - [M. Peschel] is a North American Indian shaman from Miniss Kitigan, Michigan, a member of the Ahnishinaubeg, one of the few Native American tribes (located in Northern Michigan and Southern Ontario) known to uses a mushroom [*Amanita muscaria*] in a ceremonial context.

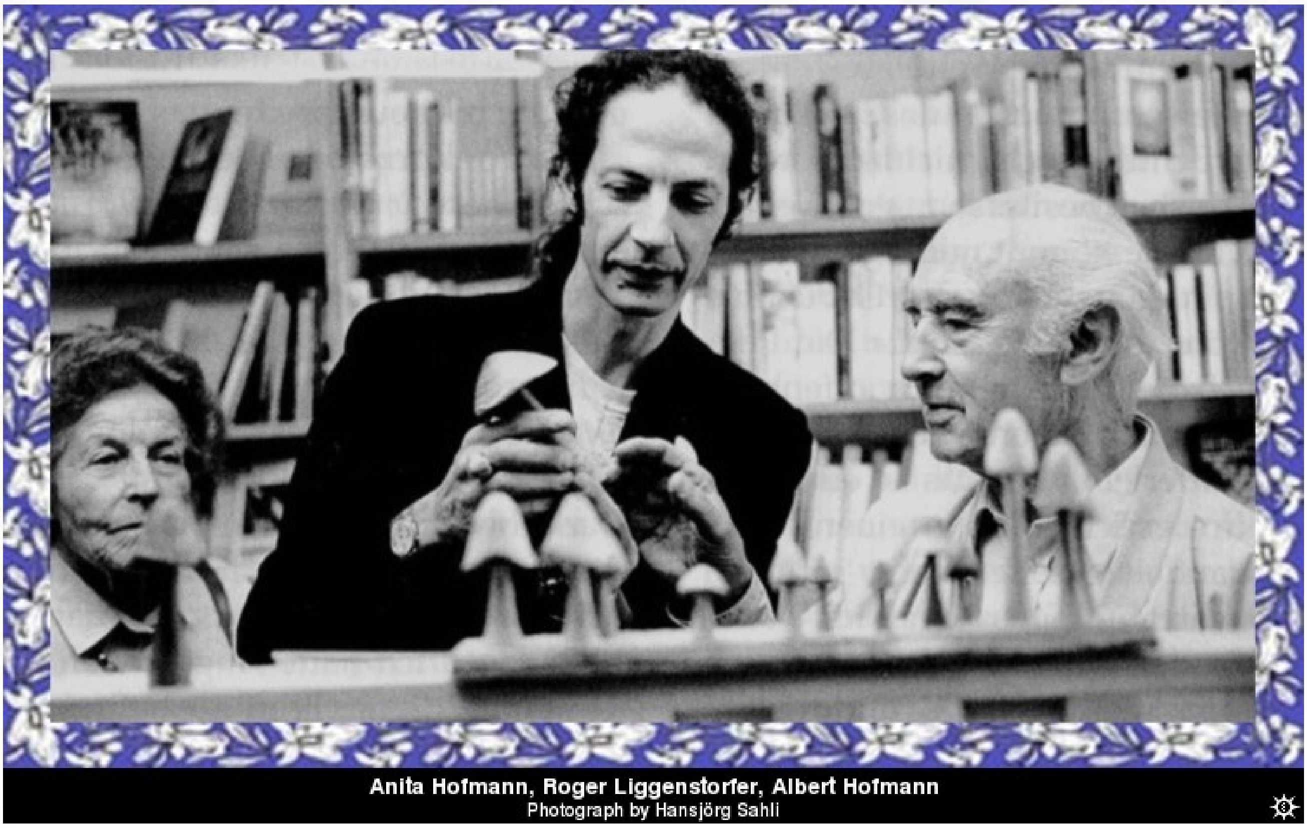
Edzard Klapp - has studied under the tuttledge of the well-known German mycologist Hans Haas (*Die Pilze Mittel-Europas*), having, at an early age, discovered the strangeness and the hidden secrets of the sacred fungi. In 1971, Klapp encountered *The Sacred Mushroom* and was began a long-time correspondence with the author John Marco Allegro. Further nurturing Allegro's beliefs, Klapp wrote an essay in 1982 (Rabenbrot). In this essay, Klapp discusses the amanita and its relationship and its association in hypothesis to the bread which the raven brought to Elija the prophet in the Holy Bible. This essay has been reprinted on many ocassions. The metalinguistic term "intentional speech" proved hereby of heurestic value. Carrying on his thesis, Klapp wrote *The Masks of the Fly Agaric* printed in *Der Fliegenpilz - Traumkult, Märchenzauber, Mythenrausch* (Aarau 2000).

Stanley Krippner - Ph.D., is Professor of Psychology at Saybrook Graduate School, San Francisco, California. He is a Fellow of the American Psychological Association, the Association of Clinical and Experimental Hypnosis, the Society for the Scientific Study of Sex, and is a Charter Fellow of the American Psychological Society and the American Academy of Clinical Sexologists. He is a member of the American Anthropological Association, the Association for the Study of Dreams, The International Council of Psychologists, the InterAmerican Psychological Association, The American Academy of Social and Political Science, the Center for Shamanic Studies, and a Charter Member of the International Society for Multiple Personality and Dissociation. He served as Director of the Dream Laboratory at Maimonides Medical Center in Brooklyn for ten years, and for three years was director of the Child Study Center, Kent State University. Dr. Krippner has been a visiting Professor at the College of Life Sciences, Bogota, Colombia and the University of Puerto Rico, and a Lecturer at the University of Minais Gerais, Belo Horizonte, Brazil. He is co-author of several books, including *The Mythic Path*, *Personal Mythology*, *Spiritual Dimensions of Healing*, and *Healing States*, co-editor of *Broken Images, Broken Selves*, and editor of *Dreamtime and Dreamwork* as well as eight volumes of *Advances in Parapsychological Research*. He has authored or co-authored over 500 journal articles, book chapters and monographs. Dr. Krippner, along with co-author Michael Winkleman, contributed a fine article on María Sabina to *The Journal of Psychoactive Drugs* and has a long term interest in shamanic medicine of Third World countries.

Weston LaBarre - is an anthropologist with a special interest in the use of entheogens by primitive societies. He is author both of *The Peyote Cult*, the definitive book on the peyote religion, and *The Ghost Dance: The Origins of Religion* and numerous journal publications on the subject of drug-use in primitive cultures.

Martin A. Lee and Bruce Shlain - are authors of *Acid Dreams: The CIA, LSD, and the Sixties Rebellion*, a book which retells the story of the CIA infiltration of R. Gordon Wasson's expedition to México in 1956. Their book also provides some insight into Timothy Leary's research at Harvard. See John Marks and Jay Stevens.

Roger Liggenstorfer - is co-editor of *María Sabina. Botin der heilige Pilze*. Liggenstorfer has contributed numerous articles to scientific publications. Additionally, Liggenstorfer also believes in "Oink" (the hidden power of *Psilocybe cyanescens*) which is derived from an experience on *Psilocybe cyanescens*, see his book on María Sabina.



Anita Hofmann, Roger Liggenstorfer, Albert Hofmann
Photograph by Hansjörg Sahli

Fig. 21. Anita Hofmann, Roger Liggenstorfer and Albert Hofmann. Photo: Hansjörg Sahli

Gary Lincoff - is president of the North American Mycological Society, employed at the New York Botanical Garden and is editor of the *Audubon Field Guide to the North American Mushrooms* and *The Simon and Schuster Mushroom Field Guide*. Lincoff has also contributed, with D. H. Mitchell, a 35-page chapter to the book *Toxic and Hallucinogenic Mushroom Poisoning*.

Frank J. Lipp - is professor in the Department of Anthropology of Duke University and has studied the use of psilocybian mushrooms among the Chinantec and Mixe of Oaxaca, México.

Bernard Lowy - was professor Emeritus in the Botany Department of Louisiana State University. He has served for 15 years as a member of the editorial board of Mycologia and contributed numerous articles on hallucinogenic mushrooms, including describing his collection of *Psilocybe mexicana* in Guatemala. He is posthumous co-author of a forthcoming book on the history of entheogenic mushrooms.

Thomas Lyttle - is editor and publisher of the now-defunct journal *Psychedelic Monographs and Essays*. Currently the editor of *Psychedelics reimagined*.

John Marks - is author of *The Search for the Manchurian Candidate*. Marks first uncovered the story of the CIA's infiltration of R. Gordon Wasson's Mexican mushroom expedition in 1956. See related information under James Moore, Jay Stevens and Lee & Shlain.

Dennis McKenna - has been involved in the interdisciplinary study of ethnopharmacology and plant hallucinogens for the past 25 years. He is co-author, with his brother Terence, of *The Invisible Landscape: Mind, Hallucinogens, and the I Ching*, a philosophical and metaphysical exploration of the ontological implications of psychedelic drugs which resulted from the two brothers' early investigations of Amazonian hallucinogens in 1971. He received his doctorate in 1984 from the University of British Columbia. His doctoral research focused on ethnopharmacological investigations of the botany, chemistry, and pharmacology of ayahuasca and oo-koo-he, two orally-active tryptamine-based hallucinogens used by indigenous peoples in the Northwest Amazon. Following the completion of his doctorate, Dr. McKenna received post-doctoral research fellowships in the Laboratory of Clinical Pharmacology, National Institute of Mental Health, and in the Department of Neurology, Stanford University School of Medicine. In 1990, he joined Shaman Pharmaceuticals as Director of Ethnopharmacology. He relocated to Minnesota in 1993 to join the Aveda Corporation, a manufacturer of natural cosmetic products, as Senior Research Pharmacognosist. He currently works as a scientific consultant to clients in the herbal, nutritional, and pharmaceutical industries. Together with two colleagues in the natural products industry, he incorporated the non-profit Institute for Natural Products Research (INPR) in October 1998 to promote research and scientific education with respect to botanical medicines and other natural medicines. Additionally, McKenna serves on the Advisory Board of the American Botanical Council, and on the Editorial Board of Phytomedicine, International Journal of Phytotherapy and Phytopharmacology.
He is a founding board member and Vice-President of the Heffter Research Institute, a non-profit scientific organization dedicated to the investigation of therapeutic applications for psychedelic plants and compounds and has also served as board member and Research Advisor to Botanical Dimensions, a non-profit organization dedicated to the investigation of ethnomedically significant plants. He was a primary organizer and key scientific collaborator for the Hoasca Project, an international biomedical study of Hoasca, a psychoactive drink used in ritual contexts by indigenous peoples and syncretic religious groups in Brasil. He has conducted extensive ethnobotanical fieldwork in the Peruvian, Colombian, and Brasilian Amazon. He has served as invited speaker at numerous scientific congresses, seminars, and symposia. Dr. McKenna is author or co-author of over 35 scientific papers in peer-reviewed journals. His publications have appeared in the *Journal of Ethnopharmacology*, *European Journal of Pharmacology*, *Brain Research*, *Journal of Neuroscience*,*Journal of Neurochemistry*, *Journal of Nervous and Mental Disease*, *Economic Botany*, and elsewhere. Additionally, Dennis McKenna and his brother Terence, using the pseudonyms O. N. Oeric and O. T. Oss, published the first popular of several psilocybin mushroom growing guides in the 1970s. In fact, it was Dennis McKenna who actually devised the technology for growing these mushrooms in jars.

Terence McKenna - was a world-renowned guru of sacred mushrooms, author, evangelistic proselyte of the Amazon and the mind; and a noted lecturer, specializing in shamanic-plants, entheogens from the Amazon and spiritual transformation. Born in 1946, McKenna has spent the last twenty-five years of his life studying the ontological foundations of shamanism, in digesting mushrooms, yopo snuff, and ayahuasca. Together with his brother Dennis he published *The Invisible Landscape: Mind, Hallucinogens and the I Ching*, a scientific and philosophical effort to explain the results of their investigations into the phenomena of time and tryptamine pharmacology.

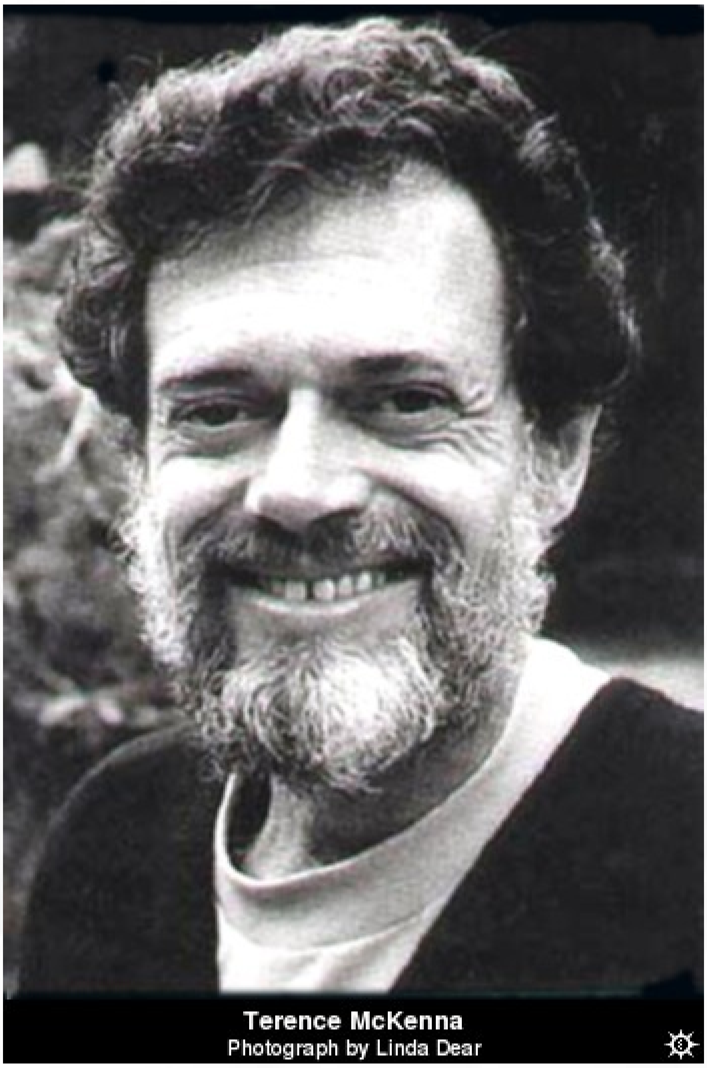


Fig. 22. Terence McKenna

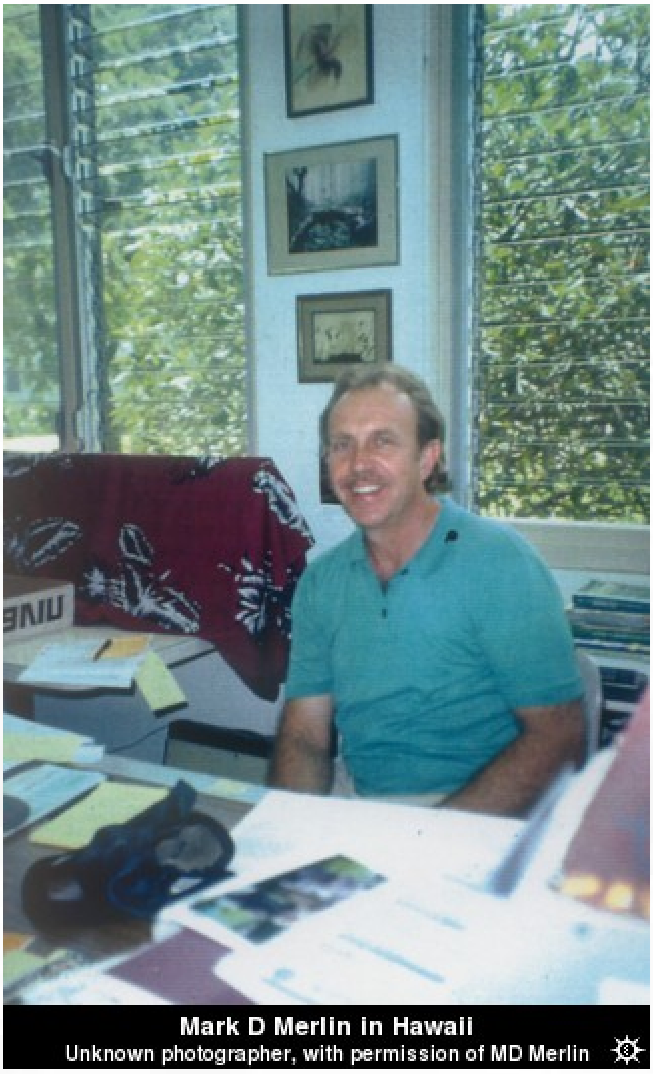
A narrative of the brothers adventures in the Amazon was the subject of a later book by Terence, *True Hallucinations*, although his last trip to the Amazon occurred in 1981 when he accompanied his brother Dennis on an expedition, sponsored by the University of British Columbia, to investigate the use of oo-koo-he, an orally active Virola hallucinogen used by the Witotos and Boras in Peru and Columbia. A graduate of the University of California at Berkeley, McKenna survived the sixties by traveling extensively in the Asian and New World Tropics and extensively studied and lectured on shamanism of the Amazon basin. Terence, along with his wife Kat Harrison and brother Dennis, was also a co-founder of Botanical Dimensions, a non-profit botanical garden on the Island of Hawai'i. Additionally, Terence was a popular lecturer among college students. Besides being co-author with his brother Dennis *The Invisible Landscape* and the classic cultivation guide written under the pseudonyms of Oeric and Oss, Terence was also the author of *Food of the Gods*. Terence passed away in April, 2000 from terminal brain cancer and he will be surely be missed by those whose paths he crossed and touched.

Gary Menser - was a real estate agent in Florence, Oregon and a past President of the Eugene, Oregon Mycological Society. He was author of Hallucinogenic and Poisonous Mushroom Field Guide (later retitled Magikal Mushroom Handbook). Menser was also an expert on truffles and their collection.

Mark D. Merlin - is a biogeographer in the Biology Program of the University of Hawai'i at Manoa with special interest in the ethnobotany and cultural history of entheogenic plants. He has published academic press books on *Cannabis* [*Man and Marijuana: Some Aspects of Their Ancient Relationship*, Fairleigh Dickinson, University Press, 1972], opium or *Papaver somniferum* [*On the Trail of the Ancient Opium Poppy*, Associated University Presses, 1984], and more recently co-authored a book kava (*Piper methysticum*), an important traditional drug-plant of many Pacific Islands [*Kava: The Pacific Drug*, Yale University Press, 1992]. The latter publication was later retitled as *Kava: The Pacific Elixer*. Dr. Merlin has also co-authored seven papers with John W. Allen on identification and non-traditional use of entheogenic mushrooms in Hawai'i and Southeast Asia.



Mark D Merlin in Hawaii
Unknown photographer, with permission of MD Merlin

Fig. 23. Mark D. Merlin
In his office, Hawaii

Richard Alan Miller - is a warlock and herbalist who co-authored with David Tatleman the first psilocybian mushroom handbook featuring color photographs for identification of psilocybian mushrooms: *The Magikal Mushroom Handbook*. Miller also wrote another book, *Magikal and Ritual Use of Herbs*. In the first edition of the latter publication, Miller reported on the (non-existent) sexual mushroom-rituals of the Mazatec Indians. However, the Indians of Oaxaca refrain from any sexual activity for three days before and after a sacred mushroom ceremony. This portion of Mr. Miller's book was removed from subsequent editions.

James Moore - was a CIA "short order cook" [a chemist] who infiltrated one of R. Gordon Wasson's mushroom expeditions to Oaxaca, México in 1956. Moore even ingested the mushrooms during a ceremony and according to Peter Stafford (1992)[120], in Moore's own words, Moore recalls that "I had a terrible cold, we damned near starved to death, and I itched all over. There was all this chanting in the dialect. Then they passed the mushrooms around, and we chewed them up. I did feel the hallucinogenic effect, although 'disoriented' would be a better word to describe my reaction." Obviously Moore had an uncomfortable experience, probably due to the fact that he was not whom he appeared to be. His mind caught up with his phoniness and placed him in an awkward and uncomfortable position. Mr. Moore eventually returned to his laboratory in Delaware where he attempted in vain to isolate the active compounds from the mushrooms - compounds which were to be used by the CIA in "non-conventional chemical warfare." Luckily for all of us, Moore was unsuccessful in this endeavor.

Henry Munn - contributed an excellent essay on the mushrooms of language (Munn, 1973)[80].

Richard Hans Norland - is author of *What's In A Mushroom? Part Three*, a book on psilocybian mushrooms which contains a lot of graphs and charts on the chemical analysis of certain species of entheogenic fungi which were collected in the Pacific Northwest region of the United States. It should be noted that Norland failed to publish *What's in a Mushroom?* Parts One and Two. Furthermore Norland also advertised a psilocybian bibliography for $5.00 in advance of publication - This volume was never published.

György-Miklos Ola'h - is a mycologist and chemist at Laval Université in Québec, Canada. In the late 1960's, Ola'h conducted several studies of the genus *Panaeolus* and published a monograph, *Le Genre Panaeolus*, identifying several species *Panaeolus* mushrooms as latent psilocybian and/or non-psilocybian. Ola'h also studied species from Southeast Asia, Africa and the Philippines.

Jonathan Ott - is an ethnopharmacognosist, natural-products chemist and botanical researcher, is considered by many to be the "Master of Entheogens." A protégé of R. Gordon Wasson, Ott was one of the original organizers of the now-famous mushroom conferences of the late 1970's. Ott is founder of Natural Products Co., a small chemical-manufacturing business based in Vashon, Washington.

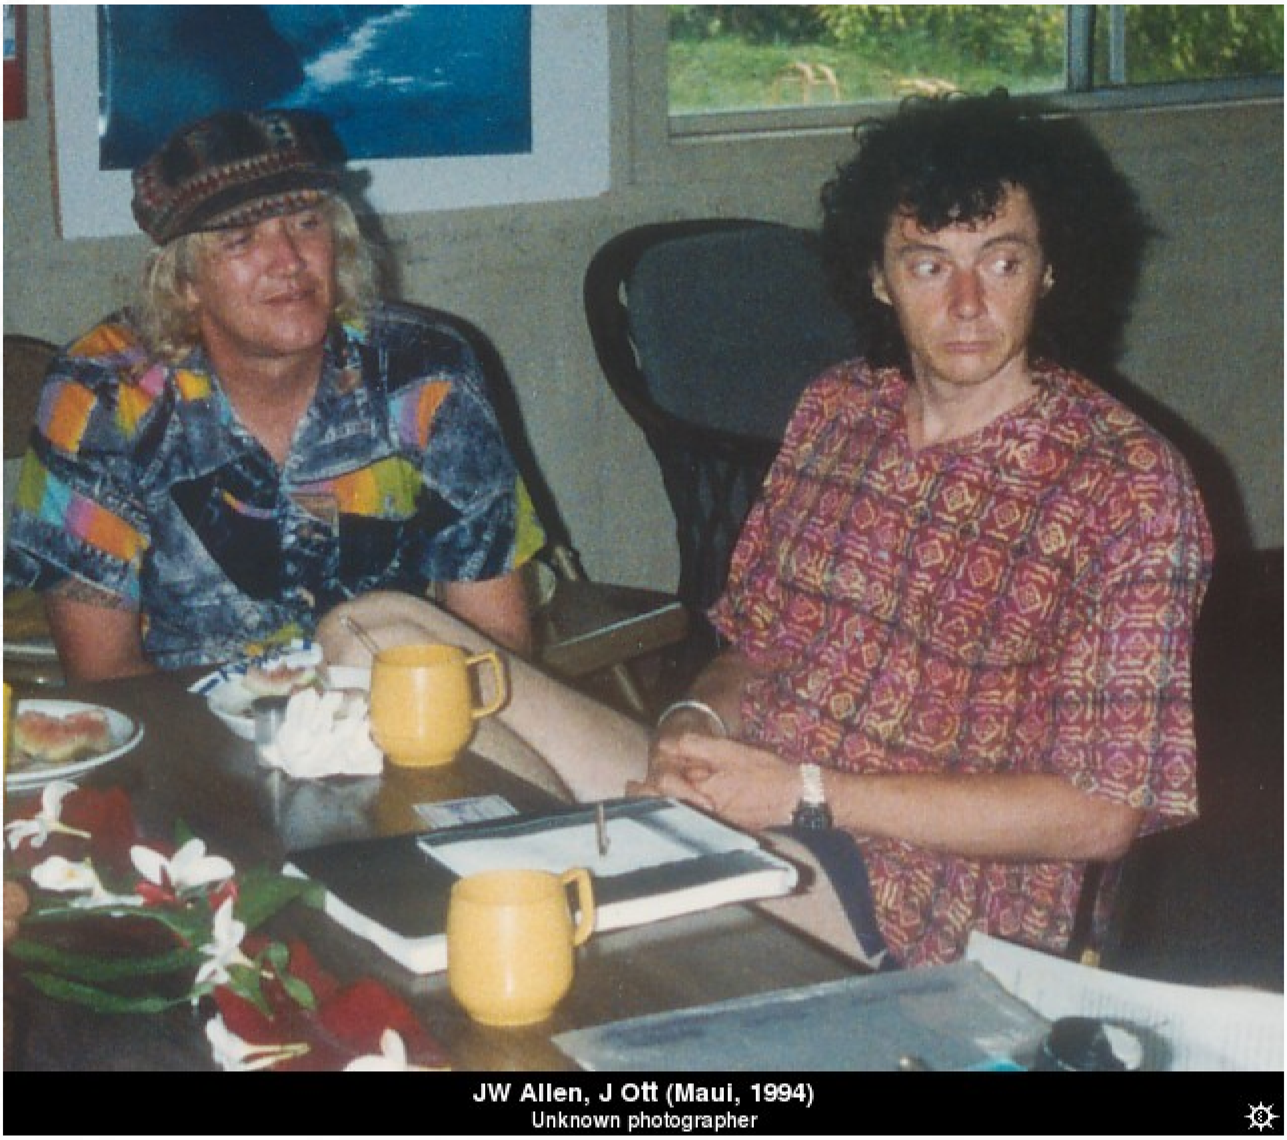


Fig. 24. John W. Allen and Jonathan Ott
Botanical Preservation Corps, Maui, 1994

He is a fellow of the Linnean Society, and a long time member of the American Association for the Advancement of Science, the Society for Economic Botany and the Society of Ethnobiology. Ott co-authored a book and paper with his friend and teacher, the late ethnomycologist R. Gordon Wasson and has also collaborated closely with Richard Evans Schultes and Albert Hofmann. Furthermore, Ott is the author of

Hallucinogenic Plants of North America, book on The Proceedings of the 2nd International Conference on Hallucinogenic Mushrooms, *Teonanácatl: Hallucinogenic Mushrooms of North America* (co-edited with Jeremy Bigwood) both out-of print, as well as *The Cacahuatl Eater: Ruminations of an Unabashed Chocolate Addict*, *Pharmacotheon: Entheogenic Drugs, their Plant Sources and History*. Most recently he published a book on the famous South American visionary-drug, *Ayahuasca Analogues*, as well as *The Age of Entheogens* and *The Angels' Dictionary* and *Pharmacophilia or the Natural Paradises*. Ott is working on a book of shamanic snuffs. Ott, together with Rob Montgomery, conducts annual seminars under the auspices of Entheobotany Seminars Corps. These annual entheogenic-plant seminars have taken place in Equador, Maui, Hawai'i, Veracruz and Palenque, Mexico.

Steven Peele - is curator and President of the Florida Mycology Research Center. At one time, Mr. Peele was the only private citizen in the United States who had a Schedule One permit for possession and sale of psilocybe spores, mushrooms and mushroom-cultures. Due to unorthodox methods for storage of such material, the DEA withdrew his permit. Peele publishes a newsletter, *The Mushroom Culture: Journal of Mushroom Cultivation* and a second Journal, *TEO: The International Journal of Psychoactive Mushrooms*.

Eunice V. Pike and Florence Cowan - are Wycliff Bible translators who lived among the Mazatec Indians of Oaxaca. They wrote two articles in *Practical Anthropology* on the Mazatecs who used magic mushrooms albeit Christian converts. These two women and Richard Evans Schultes gave R. Gordon Wasson the incentive to search for the mushroom cult he rediscovered in México.

Steven Hayden Pollock - followed in Andrew Weil's footsteps by reporting in scientific journals, a history of the contemporary use of psilocybin mushrooms as recreational drugs. Pollock also contributed several noteworthy papers on both *Psilocybe* and *Panaeolus* species to the scientific and academic communities. He was the first investigator to report on the use of visionary mushrooms in Hawai'i. Pollock was also involved in the propagation of *Psilocybe cubensis* and is noted for the marketing of what he referred to as "Cosmic Camote" or "Philosophers Stone." These epithets were given to the sclerotia of a new species discovered by Pollock, *Psilocybe tampanensis*. Pollock also produced a potent strain of *Psilocybe cubensis* which he named Matias Romero after a town in southwestern Mexico and was the first cultivator to use horse manure and straw compost for cultivating the visionary mushrooms.

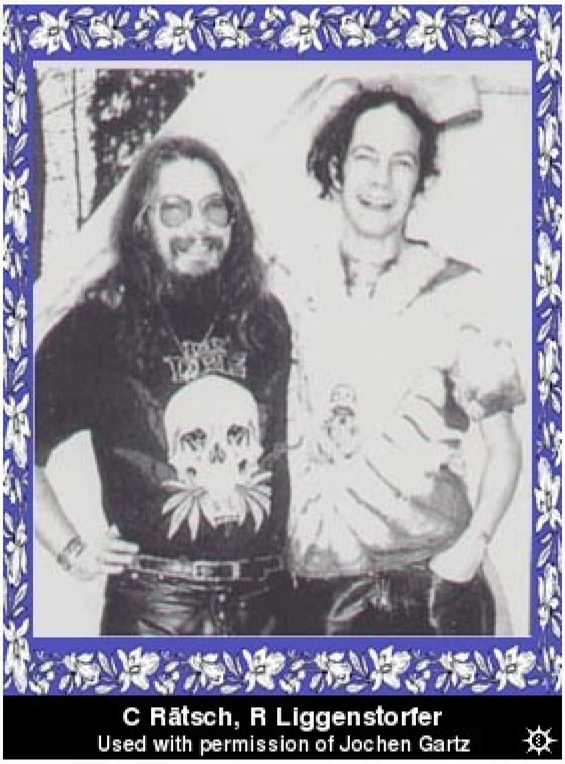
Andrija Puharich - was a man who overcame poverty and many personal tragedies who etched his way through medical school, going on and establishing a Parapsychological research foundation to oversee his medical discoveries which covered over 75 patents. Puharich was a maverick, a dedicated researcher, a rebel scientist, scorned by colleagues, and revered and encouraged by those gifted with foresightedness, including Aldous Huxley. His involvement in the field of ethnomycology began when he first filmed forays delving into the ancient mysteries and secrets of the sacred mushroom rites of the Chatino Indians of Mexico and later, on a trip to the Hawaiian Islands where Puharich, along with Hawaiian Kahuna David Bray sought evidence that a mushroom may have been used and played an important role in the early religious rites of the Hawaiian people. Unfortunately, Puharich reported that he had not uncovered any conclusive proof supporting the mushroom theory, based on documented evidence which claimed that the mushrooms, which when eaten, gave the user extra-sensory perception. It was because of the similarity between the Hawaiian word "akua" referring to the supernatural and the word "aku" with a similar meaning in five other areas of the world which brought Puharich to Hawaii. Puharich was also interested in and supported Uri Geller, UFO's and was an authority on E.L.F. (extremely low frequency magnetic fields), pollution and its effects on human organisms. His book *The Sacred Mushroom: Key to the Door of Eternity* is a classic testament to his beliefs in the historical value of these mushrooms.

Christian Rätsch - is a cultural anthropologist from Hamburg, Germany, specializing in the sacred and secular use of magical plants. His fieldwork among the Lacandos of Chiapas includes study of Datura and balché potions. Rätsch's books include *Gateway to Inner Space*, *Dictionary of Sacred and Magical Plants*, and diverse publications on the Maya, alchemy, psychedelics, aphrodisiacs and oracles. Rätsch and his colleague Roger Liggenstorfer co-authored and edited a translation of Estrada's book on the life and times of the Mexican shaman Doña María Sabina (*Maria Sabina: Botin der Heiligen Pilze*). Rätsch is also editor of *The Yearbook for Ethnomedicine and the Study of Consciousness* and author of *Enzyklopädie der psychoaktiven Pflanzen. Botanik, Ethnopharmakologie und Anwendungen*.



C Rätsch, R Liggenstorfer
Used with permission of Jochen Gartz

Fig. 26. C. Rätsch and R. Liggenstorfer

Alan B. Richardson - is a professional photographer and was a personal friend of R. Gordon Wasson. Richardson's photographs of María Sabina and her nocturnal velada graced the pages of *Life* magazine [May 13, 1957]. Richardson was the first outsider together with R. Gordon Wasson, to eat the sacred mushrooms.

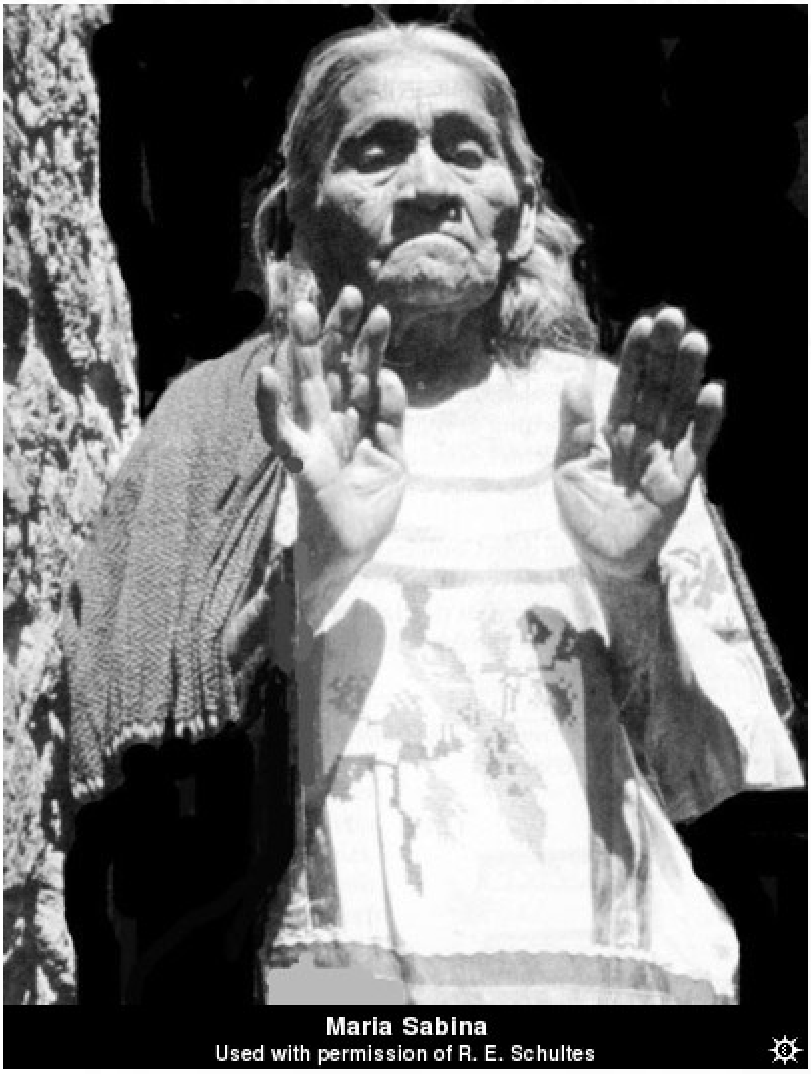
Thomas J. Riedlinger - is a researcher who was editor of *The Sacred Mushroom Seeker: Essays for R. Gordon Wasson*. This book contains numerous essays in honor of R. Gordon Wasson, written by those who knew him best.

Ronald Rippchen - is the author and editor of a German book devoted to psilocybian mushrooms. Numerous articles by well-known authors in this field are presented and the book is lavishly illustrated.

Alexandra Rosenbohm - is a German cultural anthropologist and exhibition maker who is a specialist in trance-inducing plants and mushrooms in the context of historic and contemporary shamanism and witchcraft. She has developed and organized several exhibitions regarding that subject and has published books like Halluzinogene Drogen im Schamanismus (about the use of the fly agaric in Siberia). Rosenbohm was also editor and co-author of *Schamanen zwischen Mythos und Moderne* (Leipzig 1999) and *Der Fliegenpilz - Traumkult, Märchenzauber, Mythenrausch* (Aarau 2000).

Barry Rumack and Emanuel Salzman - are authors of an excellent book with several chapters devoted to visionary mushrooms, *Mushroom Poisoning: Diagnosis and Treatment*. It provides a good section on treatment for various kinds of mushroom poisoning, including that of *Amanita muscaria*.

María Sabina - was the famous Mazatec curandera who kept alive the archaic practices of her ancestors the ancient Olmecs, Toltecs and Aztecs. It was Doña María Sabina who first initiated R. Gordon Wasson and Alan Richardson in the "magic mushrooms" of México. Through the writings of Wasson and Wasson (1957)[140], Heim and Wasson (1958)[33] and subsequent writings by others, María Sabina became world-renowned as the most famous shaman of the twentieth century. (see Allen's [1997a][3] volume I of *Ethnomycological Journals Sacred Mushroom Studies* and Estrada's [1976][17] autobiography of María Sabina).



Maria Sabina
Used with permission of R. E. Schultes

Fig. 27. Maria Sabina

Bernardino de Sahagún - was a Franciscan friar who documented the most important historical information on the use of the sacred mushrooms of the New World. It was Sahagún who first wrote down the word teonanácatl. Some other colored Spanish clergymen and historians also mentioned the sacred mushrooms in their writings - these include Juan de Córdova, Jacinto de la Serna, Diego Duran, Francisco Hernández, Alonzo de Molina, and Motolina (a pseudonym for Toribio de Benavente).

Luc Sala - is a German television personality involved in the media and various aspects of the European drug subculture. He is also the author of *Paddos: Our Little Brothers. Starter Guide of Magic Mushroom Psychonauts*. Published in the Netherlands in both English and Dutch editions.

Giorgio Samorini - is an Italian researcher of psychoactive plants and mushrooms with a special interest in the archaeology of mushroom art throughout the ages (including *Amanita* art and the art of the Tassilli plains). Samorini also has a special interest in the African entheogenic/aphrodisiac plant *Tabernanthe iboga*. Samorini is the only white person to have been initiated into the Bwiti cult of Gabon, Africa where this plant is used ceremoniously. Samorini has also studied the mycoflora of Italy.

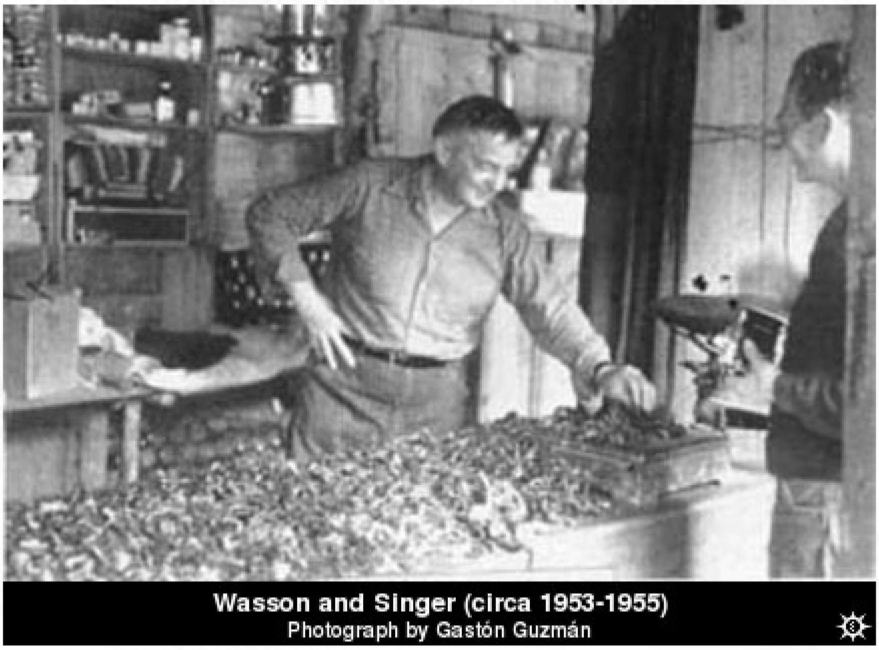
Jeremy Sandford - is the author of *In Search of the Magic Mushroom*. Sandford describes his adventures in México while seeking out the magic mushrooms he had heard so much about.

J. H. Sanford - is author of an article about the accidental ingestion of psilocybian mushrooms in Japan. Some of the case studies provided by Mr. Sanford date back to the 11th century.

Georges Scheibler - is a Swiss mycologist who published the first European guide to identification of psilocybian mushrooms. After its publication Scheibler was harassed by Swiss authorities. European narcotics agents also believed that his book would lead to widespread abuse of the mushrooms in France and other European countries.

Alexander and Ann Shulgin - are chemists and authors of *Pihkal: Phenlethylamines I Have Known and Loved* and their new monumental work *Tihkal: Tryptamines I Have Known And Loved*, a book about their interest in the tryptamine compounds and the chemistry and chemical formulae of many analogues of psilocine and psilocybine.

Rolf Singer - was a leading figure in mycology who was also a prolific writer who held important academic and research positions in Europe, North America and South America. Singer also was a Research Associate in the Department of Botany at the Field Museum of Natural History in Chicago, Illinois, from 1968-1994. Most noted for developing the nearly universally used classification for the Agaricales (mushrooms and related fungi), Singer reportedly named 86 genera, over 2460 species and infraspecies of fungi distributed in 222 genera. His 440 papers written in 9 languages, covered topics ranging from fungal systematics, nomenclature, ecology, ethnomycology, and mushroom cultivation. Singer, along with noted Michigan mycologist Alexander H. Smith, provided the academic world with the first monograph of the newly discovered species of psilocybian *Psilocybes* and their distribution in the Pacific Northwest of the United States and Mexico. Both of these intrepid scholars hold a special place in the ethnomycology of the sacred mushrooms of Mexico. After Roger Heim provided the taxonomy and naming of the first seven species recognized from México, the late mycologist, accompanied by two young Mexican botanists, M. A. Palacios and Gastón Guzmán, arrived in Oaxaca, México to conduct a taxonomic study on the Mexican mushrooms. Soon they met R. Gordon Wasson, and eventually followed his footsteps tracing the route of the sacred mushrooms throughout Oaxaca, Mexico. Later Singer and his colleague from the University of Michigan, Alexander H. Smith, co-authored a short monograph on the taxonomy of psilocybian mushrooms common in the Pacific Northwestern United States and México (including a few species from México). They also contributed a paper on the sacred mushrooms among the Aztecs and their Náhua descendants. Singer was the second author to note the possible medical use of the sacred mushrooms after Valentina P. Wasson by writing an excellent article on the curative properties of these mushrooms among some groups of indigenous peoples living in Oaxaca (Singer, 1957)[115]. Furthermore, Singer contributed numerous articles to books and journals regarding both the medical and recreational use of the sacred fungi. His book *The Agaricales in Modern Taxonomy* was the first book in modern times to discuss the idea that *Teonanácatl* was a mushroom, even providing some evidence linking the word *Teonanácatl* to certain species.



Wasson and Singer (circa 1953-1955)
Photograph by Gastón Guzmán

Fig. 28. Wasson and Singer
Oaxaca mushroom collection, circa 1953-55

Prakitsin Sihanonth - is the head of the Department of Microbiology at Chulalongkorn University in Bangkok, Thailand. Dr. Sihanonth is considered to be a leading authority on mushroom cultivation and excels in the identification of edible, poisonous and psychoactive mushrooms of Thailand.

Alexander H. Smith - was Professor Emeritus of Botany at the University of Michigan and who along with his colleague Rolf Singer, published some of the earliest papers on the occurrence of psilocybian mushrooms in the United States. Smith also once wrote a paper about the hallucinations of those who study hallucinogenic mushrooms, causing several defensive responses in privately published papers between Smith, Ott and Wasson.

Peter Stafford - is author of the *Psychedelics Encyclopedia* which covers many of the entheogenic plants used as ludible drugs by certain segments of contemporary society. This has a fine chapter on the history of entheogenic mushrooms and their pandemic ascent as a popular drug. Mr. Stafford is also a regular contributor to Bruce Eisner's *Island Views*, a quarterly publication devoted to psychedelic drugs and their social use in. Recently Stafford published a new book *Magic Grams*, containing interviews of scholars involved with entheogenic drug research and/or who's interest were similar and the pages are mingled with montages and collages.

Paul Stamets - is the Paul Bunyan of mushrooms common to the Pacific Northwest United States. Stamets has been studying mushrooms in the woods of the Pacific Northwest for more than twenty years, and has discovered and co-authored four new psilocybian mushrooms: *Psilocybe azurescens*, *P. cyanofibrillosa*, *P. liniformans* var. *americana*, and *P. weilii*. Stamets also runs a mushroomic mail-order business, Fungi Perfecti, which grows and sells gourmet and medicinal (no psilocybian) mushrooms, and conducts in-depth workshops on edible-mushroom cultivation. Stamets has lectured on psilocybian mushrooms at numerous universities and presented seminars and slide-presentations all over the world. His books include *Psilocybe Mushrooms and Their Allies* [out of print], *The Mushroom Cultivator* co-authored by Jeff S. Chilton, *Growing Gourmet and Medicinal Mushrooms*, and the recent book *Psilocybin Mushrooms of the World*.

Sam I. Stein - was an M.D. who wrote the first medical report concerning a negative reaction and bad trip after ingesting five dried grams of in vitro grown specimens of *Psilocybe cubensis* (Earle) Singer (Stein, 1958)[122]. Another important contribution was Stein's paper on the effects of *Panaeolus subbalteatus* and *Psilocybe caerulescens* in a therapeutic mode (Stein, 1959)[123].

Jay Stevens - is author of *Storming Heaven: LSD and the American Dream*. Stevens devoted three chapters of this book to the sacred mushrooms. Mr. Stevens talks about the CIA involvement with the mushrooms and the controversy of the Harvard Psilocybin Projects initiated by Timothy Leary and Jonathan Clark. See related information under the headings of John Marks, Lee and Shlain.

Jule Stevens - is co-author with Rich Gee of *How to Identify and Grow Psilocybin [sic] Mushrooms*, a field-and cultivation-guide to mushrooms of the Pacific Northwest United States and Hawai'i. This guide has step-by-step photographs of the process involved in producing good strains of *Psilocybe cubensis*.

Tjakko Stijve - was born in Utrecht (Netherlands) where he received an education in analytical chemistry. Since 1967 he has lived in Switzerland, where (until his retirement in 1999) he ran a section on food contaminants in the Quality Assurance Department of Nestle. Early on he developed an interest in the chemistry of higher fungi, resulting in the publication of many papers on mushroomic toxins and on the bioaccumulation of potentially-toxic trace-elements in macromycetes. While studying tryptophan-derivatives in the early 1980's, he came upon the tryptamines bufotenine, psilocine and psilocybine in some fungi. This awakened his curiosity about psychoactive mushrooms, and prompted him to look for the tryptamines in (at that time) unexplored genera such as *Inocybe* and *Pluteus*. In the early 1990's together with mycologist André de Meijer, he made an inventory of the psychoactive mushrooms occurring in Paraná, a province in Southern

Brazil. He is presently involved in a study on selenium and bioactive compounds in the genus Albatrellus, which will mark the end of his professional activities in mycochemistry. After his retirement, Stijve will explore a number of ethnomycological subjects.

Unknown photographer, used with permission of Tjakko Stijve

Fig. 30. Tjakko Stijve in his lab as *Psilocybe cubensis* begins to fruit, 1983.

Frederick Swain - was a student who traveled to México in the early 1960's and was graciously greeted by María Sabina who performed a mushroom ceremony for him. Swain wrote of his experience in the Journal *Tomorrow*, later reprinted in *Psychedelic Review* No. 2.

David Tatelman - is President and founder of the Homestead Book Company. By selling thousands of Mushroom kits and spores over a period of 25 years, he is directly responsible for most of the psilocybe mushrooms now cultivated in the United States. He also published one of the first field guides, *The Magickal Mushroom Handbook* and was the publisher of Paul Stamets' first book, *Psilocybin Mushrooms and Their Allies*. His genius has been in popularizing mushrooms to the masses.

Peter Vuchich - of Hongero Press was the first person to commercially sell *Psilocybe cubensis* spores, which he did by including them in his early book about cultivating mushrooms in the early 70's. Vuchich was also the first person in the United States to successfully advertise his products in *High Times* magazine selling spore kits to the general public.

Johanna Wagner - was a German ethnologist (1923-1990) who became a practicing medicine-woman (mganga) in Africa. In 1982, Dr. Wagner participated in a scientific experiment where she bioassayed fresh caps of the fly agaric. Her experiences with the fly agaric-man during an experience covering almost three days and nights, was recorded on tape and eventually published in *Ein Füllhorn göttlicher Kraft. Unter Schamanen, Gesundbetern und Wetterbeschwörern* (Berlin, 1985).

R. Gordon and Valentina Wasson - were pioneer researchers of the entheogenic mushrooms and they are also the main reason we are all here reading this manuscript. Together they coined the terms mycophobia and mycophilia. R. Gordon Wasson is also referred to as the Father of Ethnomycology. Wasson and his wife Valentina are the epitome of the heart of sacred mushrooms. In the middle 1950's, they became the first outsiders to partake of the sacred mushrooms. Gordon Wasson also studied the Aryan entheogen soma; the Kuma aborigines of New Guinea who used theragenic *Boletus* and *Russula* species, and extensively researched the use of *Amanita muscaria* among certain of Siberia. Later, he brought to the attention of the public and academic communities the discovery of a North American tribe which uses *Amanita muscaria* in a religious context [Wasson & Wasson,1957 [186]; Wasson, 1957a [140], Wasson, 1958b [143],Wasson, 1979 [173], jpd on Ojibway].

Roy Watling - is an English mycologist, the Senior Principal Scientific Officer of the Royal Botanic Garden in Edinburgh, Scotland. Watling has contributed numerous articles on the taxonomy and use of psilocybian mushrooms from Australia and Great Britain and has published papers with Gastón Guzmán.

Andrew Weil - is a recipient of an AB degree in botany from Harvard University and also worked for the National Institute of Mental Health. Currently, Dr. Weil is the director of the Program in Integrative Medicine and clinical professor of internal medicine at the University of Arizona in Tucson. As a fellow of the Institute of Current World Affairs, Weil traveled extensively in Mexico, Central and South America gathering information about medicinal plants and healing.

Fig. 34. Andrew Weil and John W. Allen
Drug Awareness Week, Oahu, Hawaii, 1988

Weil was the first investigator to report on the ludible use of psilocybian mushrooms from the Pacific Northwest United States, Colombia in South America and México. He is a graduate of Harvard Medical School who has traveled extensively writing on drug-use throughout México, Central and South America. Weil is author of *The Natural Mind*, *The Marriage of the Sun and the Moon*, *From Chocolate to Morphine*, and numerous books on holistic health and healing. It was Weil who first reported on the ludible use of *Psilocybe semilanceata* (the 'liberty-cap' mushroom) in Oregon. Weil has also contributed several papers on psilocybian mushrooms to *The Harvard Review*, *The Crimson* (Harvard's newspaper), *The Botanical Museum Leaflets of Harvard*, *The Journal of Psychedelic Drugs*, *The Journal of Altered States of Consciousness* and *Look* Magazine.

Arnold Wolman - is author of a small pamphlet on *Psilocybe cubensis*. This 16-page booklet described the collection of *P. cubensis* from the southeastern United States. This guide was published in Chicago, Illinois and was somewhat limited in its distribution.

Anthony Young - is a mycologist from Australia who has studied extensively the Genus *Panaeolus* in Australia. He has also published a review of the genus *Panaeolus* from Australia.

The above list of pioneers are the majority of the original investigators of the chemical, pharmacological, mycological and psychiatric aspects of these interesting mushrooms. The author of this book hopes that this work will stimulate and inspire other students of mushrooms into furthering their ideas and research in this field.

Acknowledgements

The author would like to thank Jonathan Ott of Natural Products of Vashon Island, Washington for his time and consideration in re-editing this book prior to publication. Furthermore, the authors also give special thanks and appreciation to Jodi Meadows and to Rodman Reynolds for their assistance in editing the original manuscript. I would also like to acknowledge the assistance of Wolfgang Bauer of Germany for his help in several of the European authors biographies and the loan of several photographs for this book. Thanks go to Tjakko Stijve for the loan of his images, and for the French Review of the CD-ROM version of this book. And a special note of gratitude to my dear friends Linda Dear, Jan and Lome Nilsson, Gastón Guzmán, Jochen Gartz, Roger Liggenstorfer, Herman de Vries, Geoffrey Brooke, Mark Merlin, David Tatelman and Richard Evans Schultes, Paige Powell and Jonathan Ott for the use of some of their photographs and drawings and to the unknown photographers who took many of the pictures of the author with these scholars.

> **Terence McKenna** has spent the last 20 years in the study of the ontological foundations of shamanism and the ethnopharmacology of spiritual transformation. He graduated from the University of California at Berkeley with a distributed major in ecology, resource conservation, and shamanism. After graduation he traveled extensively in the Asian and New World tropics, becoming specialized in the shamanism and ethnomedicine of the Amazon Basin. With his brother Dennis, he is the author of *The Invisible Landscape* and *Psilocybin: The Magic Mushroom Growers' Guide*. A talking book of his Amazon adventures, *True Hallucinations*, has also been produced. In Hawaii he is the founding secretary - treasurer of Botanical Dimensions, a tax-exempt, nonprofit research botanical garden and germ plasma repository devoted to the collection and propagation of plants of ethnopharmacological interest. In California he divides his time between writing, lecturing, and managing Lux Natura Inc., a publishing company of which he is the president and founder.

For tens of millennia human beings have been utilizing hallucinogenic mushrooms divine and to to induce shamanic ecstasy. The human-mushroom interaction is not a static symbiotic relationship but rather a dynamic one through which at least one of the parties has been bootstrapped to higher cultural levels. The impact of hallucinogenic plants on the evolution and emergence of human beings is a heretofore unexamined phenomenon, yet it promises to provide an understanding of not only primate evolution but also the emergence of the cultural forms unique to *Homo sapiens*.

At Gome National Park in Tanzania, primatologists found that one particular species of leaf kept appearing undigested in Chimpanzee dung. They found that every few days the chimps would vary from their usual pattern of eating wild fruit. Instead, they would walk for 20 minutes or longer to the site where a species of *Aspilia* was growing. They would repeatedly place their lips over an *Aspilia* leaf and hold it in their mouths. Chimps were seen to pluck a leaf, place it in their mouths, roll it around for a few moments, and then swallow it whole. In this way as many as 30 small leaves might be eaten.

Biochemist Eloy Rodriguez of the University of California, Irvine, isolated the active principle from the *Aspilia* - a reddish oil now named thiarubrine-A. Working with the same substance, Neil Towers of the University of British Columbia found that this compound can kill common bacteria in concentrations of less than one part per million. Herbarium records studied by Rodriguez and Towers showed that African peoples used the same leaves to treat wounds and stomach aches. Of the four species of *Aspilia* native to Africa, the indigenous peoples used only three, the same three utilized by the chimpanzees (Rodriguez, Aregullin, Uehara, Nishida, Wrangham, Abramowski, Finlayson, & Tower, 1985).

These findings clearly show the way a beneficial plant, once discovered by an animal or a person, can be included in the diet and thus confer an adaptive advantage. The animal or person is no longer threatened by certain environmental factors, such as diseases that may have previously set constraints on the life span of individuals of the species or on the growth of the population as a whole. This type of adaptive advantage is easily understood. Less easy to understand is the way plant hallucinogens might have provided similar yet different adaptive advantages. These compounds do not catalyze the immune system into higher states of activity, although this may be a secondary effect. Rather, they catalyze consciousness, that peculiar, self-reflecting ability that has reached its greatest apparent expression in human beings. Consciousness, like the ability to resist disease, confers an immense adaptive advantage on any individual who possesses it.

Consciousness has been called awareness of awareness (Guenther, 1966) and is characterized by novel connections among the various data of experience. Consciousness is like a super nonspecific immune response. There is no evolutionary limit to how much consciousness can be acquired by a species. And there is no end to the degree of adaptive advantage the acquisition of consciousness will confer on the individual or the species in which it resides.

There is reason to question the scenario which physical anthropologists present us regarding the emergence of human consciousness out of binocular, bipedal primates. The amount of time allotted to this ontological transformation of animal organization is excessively brief. Evolution in higher animals takes a very long time to occur. For example, the biologist who studies the evolution of the early amphibians rarely operates in time spans of less than 100 thousand years and often speaks in terms of millions of years. But the emergence of man from the higher primates is something that has gone on in less than a million years. Physically humans apparently have changed very little in the last million years. But the amazing proliferation of consciousness, social institutions, coding practices, and cultures has come so quickly that it is difficult for modern evolutionary biologists to account for it. Most do not even attempt an explanation.

There is a hidden factor in the evolution of human beings that is neither a "missing link" nor a *telos* imparted from on high. This hidden factor in the evolution of human beings, the factor that called human consciousness forth from a bipedal ape with binocular vision, involved a feedback loop with plant hallucinogens. This is not an idea that has been widely explored, although a very conservative form of this notion appears in R. Gordon Wasson's *Soma. Divine Mushroom of Immortality* (Wasson, 1971). Wasson does not comment on the emergence of humanness out of the primates but does suggest hallucinogenic mushrooms as the causal agent in the appearance of spiritually aware human beings and the genesis of religion. Wasson feels that omnivorous foraging humans would have eventually encountered hallucinogenic mushrooms or other psychoactive plants in their environment.

The strategy of these early human omnivores was to eat everything and to vomit whatever was unpalatable. Plants found to be edible by this method were then inculcated into their diet. The mushrooms would be especially noticeable because of their unusual form and color. The state of consciousness induced by the mushrooms or other hallucinogens would provide a reason for foraging humans to return repeatedly to those plants in order to reexperience their bewitching novelty. This process would create what C. H. Waddington (1961) called a "creode," a pathway of developmental activity (in other words, a habit).

Habituation to the experience was insured simply because it was ecstatic. "Ecstatic" is a word unnecessary to define except operationally: An ecstatic experience is one that one wishes to have over and over again. It has been shown in experimental situations that if one creates a situation in which *N,N*-di-methyltryptamine (DMT) can be delivered to a monkey on demand, then a large number of monkeys exposed to that experimental apparatus will prefer the DMT over food and water. DMT was used in these experiments because it is a very short-acting, overt hallucinogen that occurs in many different plant species (Jacobs, 1984). Although we cannot analyze the laboratory monkeys' state of mind, it is very clear that something in the experience impels them to return to the stimulus again and again.

Wasson's idea that religion originated when an omnivorous protohuman encountered alkaloids in the environment was countered by Mircea Eliade (1964), the most brilliant expositor of the anthropology of shamanism and the author of *Shamanism: Archaic Techniques of Ecstasy*. Eliade considers what he calls "narcotic" shamanism to be decadent. He feels that if one cannot achieve ecstasy without drugs, then one's culture is probably in a decadent phase. The use of the word *narcotic* - a term usually used for soporifics - to describe this form of shamanism betrays an unsettling botanical and pharmacological naivete. Wasson's notion, which I share, is precisely the opposite: It is the presence of a hallucinogen in a shamanizing culture that indicates its shamanism is authentic and alive. It is the late and decadent phase of shamanism that is characterized by elaborate rituals, ordeals, and reliance on pathological personalities. Wherever these latter phenomena are central, shamanism is well on its way to becoming simply "religion."

One view of plant hallucinogens is to see them as interspecies messages or exopheromones. Pheromones are chemical compounds exuded by an organism for the purpose of carrying messages between organisms of the same species. The meaning of the message is not intrinsic in the pheromone's chemical structure but in evolutionarily established convention. Ants, for instance, produce a number of secretions with very specific meanings for other ants. However, these chemical "languages" are species-specific: the ant of one species cannot "read" the pheromones of another species. In fact there is one known case where a pheromone means one thing to one ant species and yet bears a completely different meaning to another ant species, much in the same way that the English word "no" means "yes" in Greek.

If hallucinogens are operating as exopheromones, then the dynamic symbiotic relationship between primate and hallucinogenic plant is actually a transfer of information from one species to another. The primate gains increased visual acuity and access to the transcendent Other, while the benefits to the mushroom arise out of the primate domestication of previously wild cattle and hence the expansion of the niche occupied by the mushroom. Where plant hallucinogens do not occur, such processes cannot take place, but in the presence of hallucinogens a culture is slowly introduced to increasingly more novel information, sensory input, and behavior and thus is bootstrapped to higher states of self-reflection.

Human language arose out of the synergy of primate organizational potential by plant hallucinogens. Indeed this possibility was brilliantly anticipated by Henry Munn in his essay "The Mushrooms of Language" (1973). Munn writes:

> Language is an ecstatic activity of signification. Intoxicated by the mushrooms, the fluency, the ease, the aptness of expression one becomes capable of are such that one is astounded by the words that issue forth from the contact of the intention of articulation with the matter of experience. The spontaneity the mushrooms liberate is not only perceptual, but linguistic. For the shaman, it is as if existence were uttering itself through him. (pp. 88-89)

Other writers have sensed the importance of hallucinations as catalysts of human psychic organization: - Julian Jaynes' theory, presented in his controversial book *The Origins of Consciousness in the Breakdown of the Bicameral Mind* (1977), makes the point that there may have been major shifts in human self-definition even in historical times. He proposes that through Homeric times people did not have the kind of interior psychic organization that we take for granted. What we call ego was for pre-Homeric people what they called a "god." When danger threatened suddenly and unbidden, the god's voice was heard in the individual's mind, a kind of metaprogram for survival called forth under great stress. This integrative psychic function was perceived by those experiencing it to be either the direct voice of a god, or that of the leader of the society (king), or of the dead king, the king in the afterlife. Merchants and traders moving from one society to another brought the unwelcome news that the gods were saying different things in different places, and thus cast early seeds of doubt. At some point people integrated (in the Jungian sense) this previously autonomous function, and each person *became* the god and reinterpreted the inner voice as the "self" or, as it was later called, the "ego."

Hallucinogenic plants may have been the catalysts for everything about us that distinguishes us from other primates except perhaps the loss of body hair. All of the mental functions - that we associate with humanness, including recall, projective imagination, language, naming, magical speech, dance, and a sense of *religio* may have emerged out of interaction with hallucinogenic plants. Our society, more than others, will find this theory difficult to accept because we have made pharmacologically obtained ecstasy a taboo. Sexuality is a taboo for the same reason: such things are consciously or unconsciously sensed to be entwined with the mysteries of where we came from and how we got to be the way we are. A theory of plant hallucinogens as central to the origin of mind suggests a scenario such as the following.

We know that the Sahara was much wetter as recently as 4 or 5 thousand years ago. The Roman historian Pliny referred to North Africa as "Rome's breadbasket." The presumption is that over the last 150 thousand years the Sahara has grown gradually drier, changing from a subtropical forest to grasslands and recently, to desert. When the grasslands first appeared, the arboreal adaptation of the primates ill served their continued survival. They left the trees and began to foray onto the grasslands. Their arboreally evolved repertoire of troop signals came under pressure to further expand. It was the generation of hunting pack signals, such as occurs in wolves and dogs, that served as the basis for language. But another result of moving out of the trees and onto the grasslands was the likelihood of encountering the manure of ungulate herbivores, and, in the same situation, coprophilic (dung-loving) mushrooms. Several species of psilocybin-containing mushrooms are coprophilic; *Amanita muscaria*, which has a symbiotic relationship to birch and fir trees, does not.

The far fewer number of plant species that characterize grasslands in contrast with forests make it highly likely that any grassland plant encountered would be tested for its food potential. The eminent geographer Carl Saur felt that there was no such thing as a natural grassland. He suggested that all grasslands were human artifacts resulting from burning. He based this argument on the fact that all grassland species can be found present in the understory of the forests at the edge of the grassland, but a very high percentage of the forest species are absent in the grasslands. From this he argued that the grasslands are so recent that they must be seen as concomitant with the rise of large human populations (Saur, 1973).

The next step in the cultural evolution of the bipedal pack-hunting primates was the domestication of some of the browsing herbivores. With the animals and their manure came the mushrooms, and the human-mushroom relationship was further enhanced and deepened.

Evidence for these speculations can be found in southern Algeria. There is an area called the Tassili plateau, a curious geological formation. It is like a labyrinth, a vast badlands of stone escarpments that have been cut by the wind into many perpendicular narrow corridors, almost like an abandoned city. And in the Tassili there are rock paintings that date from the late neolithic to as recently as 2 thousand years ago. Here are the earliest known depictions of shamans in coincidence with large numbers of grazing animals, specifically cattle (Lhote, 1959; Lajoux, 1963). The shamans, dancing and holding fistfuls of mushrooms, also have mushrooms sprouting out of their bodies. This connection between the Tassili art and mushroom use was discovered and pointed out to me by Jeff Gaines, an ethnomycologist and art historian living in Boulder, Colorado. He recognized the implications of the Tassili images for the role of mushroom use in human prehistory. Similar images occur in pre-Colombian Peruvian textiles wherein the shaman is shown holding an object that has been identified as either a "chopper" or "mushroom." Chopping tools have been found that resemble the depicted object. Unlike the Peruvian images, with the Tassili frescoes the case is clear. Here we see dancing shamans with six, eight, or ten mushrooms clutched in their hands and sprouting from their bodies.

The herding peoples who produced the Tassili paintings moved out of Africa over a long period of time, perhaps from 30 thousand to 5 thousand years ago. Wherever they went, their pastoral lifestyle went with them. The Red Sea was landlocked at that time. The boot of Arabia was backed up against the African continent. The landbridge there was utilized by some of these African pastoralists to enter the fertile crescent and later Asia Minor, where they intermingled with populations already present and became well-established by 12 thousand years ago. These pastoral people had a cult of cattle and one of the Great Goddess. The evidence for this comes from a number of sites in southern Anatolia, the best researched being Catal Hüyük, a site dated to 8-9,000 BP. Catal Hüyük has been thoroughly excavated and contains amazing shrines with cattle bas-refiefs and heads of the cattle covered with ocher designs - the very complex paintings of a very complicated civilization (Mellaart, 1965, 1967).

In the confluence of the cult of the Great Goddess and the cattle cult, there is a recognition and an awareness of the mushroom as the third and chthonic member of a kind of late neolithic trinity. The mushroom, seen to be as much a product of the cattle as milk, meat, and manure, was the pipeline to the presence of the Goddess. Recently Riane Eisler (1987), in her important revisioning of history *The Chalice and the Blade*, has advanced the important notion of "partnership" models of society being in competition and oppressed by "dominator" forms of social organization. These latter are hierarchical, paternalistic, materialistic, and male dominated. Her position is that it is the tension between these two forms of social organization and the overexpression of the dominator model that are responsible for our alienation. I am in complete agreement with Eisler's view. In fact this essay asks a two-point question that is an extension of her argument. What factor maintained the equilibrium of the partnership societies of the late neolithic, and what factor faded, thereby setting the stage for the emergence of the evolutionarily maladaptive dominator model?

It is the depth of the relationship of a human group to the gnosis of the vegetable mind, the Gaian collectivity of organic life, that determines the strength of the group's connection to the archetype of the Goddess and hence to the partnership style of social organization. The last time that the mainstream of Western thought was refreshed by the gnosis of the vegetable mind was at the close of the Hellenistic era, when the Eleusianian Mysteries were finally suppressed by enthusiastic Christian barbarians (Wasson, Hofmann, & Ruck, 1978).

The late medieval church that conducted the great witch burnings was very concerned that all credit for episodes of magic and derangement should be given to the Devil - hence, knowledge of plants such as Datura, deadly nightshade, and monkshood and the role that they were playing in the nocturnal gatherings and activities of the practitioners of the craft were suppressed. After all, we cannot have a Devil who is such a diminished figure that he must rely on mere herbs to work his wiles. The Devil must be a worthy foe of the Christos, and hence nearly coequal (Duerr, 1985).

My conclusion is that taking the next evolutionary step - the archaic revival, the rebirth of the Goddess, and the ending of profane history - are agendas that implicitly contain the notion of our reinvolvement with and the emergence of the vegetable mind. That same mind that coaxed us into self-reflecting language now offers us the boundless landscapes of the imagination. Without such a relationship to psychedelic exopheromones regulating our symbiotic relationship with the plant kingdom, we stand outside of an understanding of planetary purpose. And understanding planetary purpose may be the major contribution that we can make to the evolutionary process. Returning to the bosom of the planetary partnership means trading the point of view of the male-created ego for the intuitional translinguistic understanding of the maternal matrix.

The people of Catal Hüyük and other Mesopotamian peoples existed undisturbed in the ancient Middle East for a long time, practicing their Mother Goddess religion. Then, around 5-7,000 BP, a different kind of people with wheeled chariots, patriarchy, and a ritual involving horse sacrifice swept down from north of the Caspian Sea into Turkey, Anatolia, and what is now Iraq and Iran, encountering the pastoral, mushroom-using lowlanders. These invaders are the people that Wasson has suggested were the bearers of Soma. He feels that Soma, the intoxicating plant of the Vedic hymns, may have been the mushroom *Amanita muscaria*. A mushroom mystery cult was carried out of the forests of Central Asia by Aryan people who eventually settled in India.

The problem with this hypothesis is that *A. muscaria* is not a reliable visionary hallucinogen. It is difficult to obtain a consistently ecstatic intoxication from *Amanita muscaria*. Much ink has been shed over this problem. Some have suggested that *A. muscaria* must be pounded with milk curd in order to decarboxalate muscarine, the active toxin, into muscamol, the hallucinogenic constituent. Others have suggested that the *Amanita* must be dried or roasted and aged before it is rendered nontoxic and effective. The fact of the matter is that muscamol is not a deep hallucinogen, even when used as a pure compound. Wasson was on the right track, correctly recognizing the potential of *Amanita muscaria* to induce religious feeling and ecstasy but did not take into account the imagination and linguistic stimulation imparted by the input of African psilocybin-containing mushrooms into the evolution of Old World mycolatry.

We know that at least one psilocybin mushroom, *Psilocybe cubensis* or *Stropharia cubensis*, is circumtropical in its distribution, occurring throughout the warm, wet tropics wherever cattle of the *Bos indicus* type are present. This raises a number of questions. Is *P. cubensis* exclusively a creature of the manure of *Bos indicus*, or can it occur in the manure of other cattle? How recently has it reached its various habitats? The first specimen of *Psilocybe cubensis* was collected by Earle in Cuba in 1906, yet current botanical theory places the actual point of origin for the species in Kampuchea. An archaeological dig in Thailand at a place called Non Nak Tha has been dated to 15,000 BP, and there the bones of *Bos indicus* have been found coincident with human graves. Some of the bones have burned-out centers, indicating that they had been used as *chillums* to bum and presumably smoke vegetable material. *Chillums* of the Non Nak Tha type are used even today among yoga-saddhus throughout India. *Psilocybe cubensis* is common in the Non Nak Tha area today.

At what point, then, did *P. cubensis* enter the New World? In southern Mexico, coincident with the Mayan cultural area, natives use a number of psilocybin-containing mushrooms: *Psilocybe mexicana*, *P. aztecorum*, *P. maztecorum*, and others. These mushrooms constitute the Mexican mushroom complex discovered by Valentina and Gordon Wasson in the early fifties. *Psilocybe cubensis* also occurs in these areas, being especially prolific at Palenque. Palenque is the site of the ruins of one of the most exquisite cities of the Mayan climax. Many people have taken the mushrooms at Palenque and have had the impression that they were ingesting the sacred sacrament of the people who built this fabulous abandoned 7th-century Mayan city, but this notion is disputed by modern botanists. We cannot be certain that *P. cubensis* was the mushroom sacrament of the Maya. Most orthodox botanists argue that *P. cubensis* entered the New World with the conquest, transported by the Spanish and their cattle. In the absence of a decipherment of the Mayan glyphs, it is not easy to imagine how such a matter could be proved or disproved. Given the long viability of the spores and the generally prevailing winds at the equator, the circumtropical distribution of *P. cubensis* is probably a very old fact of the ecology of the planet.

The Indo-Aryan people coming out of central Asia contacted valley-dwelling, pastoral, partnership cultures and assimilated from them the cult of the coprophitic psilocybin-containing mushroom, carrying it eastward into India. The evidence is thin but, on the other hand, the evidence has not been sought. After all, the current desert climate of the region encompassing Iraq, Iran, southern Turkey, Jordan, and Saudi Arabia makes this a very unlikely place to look for archaeological evidence of a mushroom cult. However, Robert Graves's book

Food for Centaurs (1960) discusses how a taboo usually indicates an earlier historical involvement with the forbidden item in the inventory of the culture. And mushrooms, which are hardly found in the contemporary environment where these religions are practiced, are very taboo in the substratum of primitive Zoroastrianism, Mandaeanism, and the undifferentiated cult religions that preceded them. Mandaeanism specifically forbids the eating of mushrooms, according to Wasson (Wasson, Hofmann, & Ruck, 1978).

In *The Sacred Mushroom and the Cross* (1970), John Allegro, concentrating on post-exilic Judaism in Palestine, makes a controversial case that can only be judged by Sumerian philologists. He posits that there are mushroom words, phrases, and symbols that can be traced through Accadian into old Accadian and back into Sumerian, and that mushrooms were used very early in this area. My own approach has been to work forward from the Vedas. The Vedas are hymns that these Indo-Aryan people composed somewhere along their millennia-long peregrinations in India. The Ninth Mandala of the *Rig Veda* especially goes into great detail about Soma and states that Soma stands above the Gods. Soma is the supreme entity. Soma is the moon; Soma is masculine. Here we have a rare phenomenon: a male lunar deity. The connection between the feminine and the moon is so deep and obvious that a lunar male deity stands out, making its traditional history in the region easy to trace.

I reexamined the mythologies of the Near East trying to find a lunar god that would prove that this idea had been imported to India from the West. I found that the Sumerian civilization's northernmost outpost was a city called Harran, a city traditionally associated with the beginning of astrology. Invented in Harran, astrology spread to China, later to Egypt, and throughout the ancient world. The patron deity of the city of Harran was a moon god: Sin or Nannar. Sin was male and wore a cap that looked like a mushroom. No other deity in that pantheon had this headgear. I found three examples of Sin or Nannar on cylinder seals, and in each case the headgear was prominent, and in one instance the accompanying text by a nineteenth-century scholar mentions that this headgear was in fact the identifier for the god (Maspero, 1894).

Why was the Aryan deity connected with the mushroom perceived as male? Although this is a problem for folklorists and mythologists, certain points are obvious. German folklore has always associated the moon with the masculine, and the mushroom will take the projection of masculinity or femininity with equal ease. It is obviously connected to the moon: it has a lustrous, silvery appearance in certain forms, and it seems to appear at night when the moon rules the heavens. On the other hand, one can shift the point of view and suddenly see the mushroom as masculine: it is solar in color, phallic in appearance, and imparts a great energy. So the mushroom is actually an androgynous shape-shifting deity that can take various forms relative to the predisposition of the culture encountering it. One can almost say that it is a mirror of cultural expectations. That is why for the Indo-Aryans it took on a masculine quality and why in other situations it seems to have a very lunar quality. Either way, it is a hallucinogen that is not wild and is associated with the domestication of animals and with human culture. This association with domesticated animals implicates the mushrooms in the cultural development of the Indo-Aryans, the people who wrote the Vedas.

These same Aryans were the authors of a breakthrough in religious ontology. For them there were no sacred rivers, no sacred trees, and no holy mountains. They transcended geography in their notion of deity. They built a fire, and where the fire was human consciousness emerged into the light kindled, the center of the universe came to rest. They had discovered the transcendence of time and space. A sacramental plant hallucinogen that is linked to the dung of domesticated animals means that the sacrament is as nomadic as the people and animals that provide its favored milieu.

There are a number of problems with this theory, one of which is the lack of confirmation in India of the presence of *Psilocybe cubensis* or other psilocybin-containing mushrooms. *Amanita muscaria* is also rare in India. I predict, however, that a careful search of the flora of India will reveal *P. cubensis* as an indigenous component of the biome of the subcontinent. And I maintain that the desertification of the entire area from North Africa to the Tarr region around Delhi has distorted our conception of what occurred in the prehistoric evolution of religious ontology when these civilizations were in their infancy and the area was much wetter. The mushroom religion is actually the generic religion of human beings, and all later adumbrations of religion stem from the cult of ritual ingestion of mushrooms to induce ecstasy.

A rethinking of the role that hallucinogenic plants and fungi have played in the promotion of human emergence from the substrata of primate organization can help to lay the basis for a new appreciation of the unique confluence of factors responsible and necessary for the evolution of human beings. The widely felt intuition of the presence of the Other as a female companion to the human navigation of history can, I believe, be traced back to the immersion in the vegetable mind that provided the ritual context in which of self-awareness, self-reflection, and self-articulation: the light of the Great Goddess.

Mushrooms and the mind

by

Ralph Metzner

original source: http://www.drugtext.org/The-Psychedelics/mushrooms-and-the-mind.html

Was the Buddha's last, fatal supper a mushroom feast? Was soma, the mystery potion at Eleusis, a mushroom? Why are mushrooms linked to thunder, and to toads? Why does Hieronymus Bosch have a gigantic mushroom standing at Hell's entrance? Why have they been called "God's Flesh," and "Devil's Bread"? Men have used mushrooms to murder, to worship, to heal, to prophesy. Some fear and abominate all fungi as "dirty" and "dangerous." Others use discrimination-enjoy them as food and as mediators to divine vision.

Two classes of mushrooms are of primary interest to the anthropologist and psychologist studying the ritual use of fungi. One, the fly agaric, Amanita muscaria, is the "drug of choice" among certain Siberian tribes. It is apparently hallucinogenic, though not psychedelic in the sense of inducing transcendent experiences, experiences of expanded consciousness. The other group, the Psilocybe mushrooms and related species of the Mexican mountains, are both hallucinogenic and psychedelic. They are the "God's Flesh" of the Aztecs.

The Fly Amanita

The fly agaric has a whitish stalk, swollen at the base, a lacerated collar about three quarters of the way up the stalk, and a gorgeously colored umbrella-like cap from three to eight inches wide. In North America the cap will be mostly whitish, yellowish, or orange-red, but in Europe or Asia bright red or purple. In all regions the cap is covered with many whitish, yellowish, or reddish warts[1].

Tribes using the fly agaric include the Kamchadals, Kerjaks, and Chukchees living on the Pacific coast, from Kamchatka to the northeastern tip of Siberia; the Yukaghirs, farther to the west; the Yenisei Ostjaks; and the Samoyed Ostjaks, in the valley of the upper Ob. These Siberian tribes have become famous for the practice of drinking the urine of mushroom-intoxicated persons, in order to get a prolongation of the effect. Oliver Goldsmith, in 1762, described a "mushroom party" thus:

> The poorer sort, who love mushrooms to distraction as well as the rich, but cannot afford it at first hand, post themselves on these occasions around the huts of the rich and watch - theladies and gentlemen as they come down to pass their liquor, and hold a wooden bowl to catch the delicious fluid, very little altered by filtration, being still strongly tinctured with the intoxicating quality. Of this they drink with the utmost satisfaction and thus they get as drunk and as jovial as their betters[2].

Whether the fly agaric is involved in the "berserkgang" of the Vikings is a debated point. Norman Taylor's book Narcotics: Nature's Dangerous Gifts, claims that "in proper amounts it promotes gaiety and exuberance among a morose people, while leading, in large doses, to berserk orgies."[3] R. Gordon Wasson, however, has dissented from this view, pointing out that no plant was ever mentioned in the Viking accounts.

In their monumental book Mushrooms, Russia and History (1957), the Wassons, Robert Gordon and Valentina, draw parallels between the beliefs of the Siberian tribes about the mushrooms and those of the Mexican mushroom-using peoples:

> With our Mexican experiences fresh in mind, we reread what Jochelson and Bogoras had written about the Korjaks and the Chukchees. We discovered startling parallels between the use of the fly amanita (Amanita muscaria) in Siberia and the divine mushrooms in Middle America. In Mexico the mushroom "speaks" to the eater; in Siberia "the spirits of the mushrooms" speak. Just as in Mexico, Jochelson says that among the Korjaks "the agaric would tell every man, even if he were not a shaman, what ailed him when he was sick, or explain a dream to him, or show him the

> upper world or the underground world or foretell what would happen to him." Just as in Mexico on the following day those who have taken the mushrooms compare their experiences, so in Siberia, according to Jochelson, the Korjaks, "when the intoxication had passed, told whither the 'fly-agaric men' had taken them and what they had seen." In Bogoras we discover a link between the lightning bolt and the mushroom. According to a Chukchee myth, lightning is a One-Sided Man who drags his sister along by her foot. As she bumps along the floor of heaven, the noise of her bumping makes the thunder. Her urine is the rain, and she is possessed by the spirits of the fly amanita[4].

Much is made by Wasson of the connection between mushrooms and thunder; we will return to this later.

Dr. Andrija Puharich, whose work has chiefly concerned itself with the experimental investigation of telepathic and related phenomena, has also done some studies of mushroom use among the Chatino Indians of Mexico, and claims that amanita is used by them. Wasson, whose knowledge of the Mexican mushrooms is probably unequaled, disputes this:

> For ten years we combed the various regions, and we have invariably found that it played no role in the life of the Indians, though of course it is of common occurrence in the woods. We had visited the Chatino country, where we were accompanied by Bill Upson of the Instituto Linguistico de Verano, who speaks Chatino. Later he likewise helped Puharich, but he informs us that no *brujo* in his presence testified to the use of a mushroom answering to the description of Amanita muscaria[5].

The three principal ingredients of Amanita muscaria apparently are muscarine, atropine, and bufotenine[6]. Muscarine is a cholinergic drug, which stimulates the parasympathetic system, causing sweating, salivation, pupil contraction, slowed cardiac rate, and increased peristalsis. These effects are counteracted by atropine, which was long used as an antidote to amanita poisoning until it was discovered that the mushroom itself also contained this. The effects of a particular ingestion of the mushroom would depend on the relative quantities of the two substances. Atropine alkaloids are found in many plants, including deadly nightshade, henbane, mandrake, thorn apple, and Jimsonweed. They are generally believed to have been involved in the European witches' cults, definitely to cause hallucinations, as well as either excitement or depression. On the basis of my own experiments with Ditran, a hallucinogenic drug similar in its action to atropine, I would suggest that the anti-cholinergic agents are definitely consciousness-altering, since they produce thought disorientation and visions, but I would doubt that they are psychedelic, or consciousness-expanding. They may be more truly psychotomimetic than LSD or psilocybin[7].

The third ingredient of the amanita mushrooms, bufotenine, probably is psychedelic, since chemically it is 5-hydroxydimethyltryptamine, i.e., closely related to both DMT and psilocin. Bufotenine is also found in the South American snuff *Piptadenia peregrina* and in the sweat gland of the toad *Bufo marinus*, which sheds new light on the witches' brews containing toads. However, the quantity of bufotenine in Amanita muscaria is very small, so the principal visual effects of the mushroom are probably due to its belladonna (atropine) alkaloids. This is confirmed by the stories of the Siberian tribesmen who, having imbibed the mushrooms, jump very high over small objects; visual size distortions are common with Ditran-type drugs, though rare with tryptamine psychedelics.

Although to some people the drinking of muscarinic, atropinized urine may be a repulsive way to get high, as Norman Taylor points out, "Who are we to deny them this revolting pleasure? To these dull plodders of the arctic wastes, the fly agaric may well be their only peep into a world far removed from the frozen reality of their wretchedness. That such people found the fly agaric is merely another illustration of the worldwide hunt for something to break the impact of everyday life."[8]

The Sacred Psilocybes

The story of the Psilocybe mushrooms, the teonanacatl, or "God's Flesh," of the Aztecs, is one of the most dramatic episodes in modern anthropology. When the Spaniards arrived in Mexico, their clerics immediately labeled the mushrooms (and the other hallucinogens in use-peyotl and olohuhqui) as products of the devil and did their best to stamp out this "idolatry." Brother Toribio de Benavente, a Spanish monk better known as Motolinia, in a work on pagan rites and idolatries, described their "vice" as follows:

> They had another drunkenness which made them more cruel: which was of some small mushrooms ... and after a while they were seeing a thousand visions, especially of snakes, and as they went completely out of their minds, it seemed to them that their legs and bodies were full of worms which were eating them alive, and thus, half raving, they went out of the house, wishing that somebody would kill them, and with that bestial drunkenness and the trouble they felt, it would happen sometimes that they hanged themselves. And they were also against others much more cruel. They called these mushrooms teonanacatl, which means flesh of the God (the Demon they adored), and in that manner, with that bitter food, their cruel god held communion with them[9].

A Mexican historian writing in the 1870s, Orozco y Berra, stated that the mushrooms produced "a state of intoxication with frightening hallucinations." Friar Bernardino de Sahagun, a Franciscan monk who preserved texts written in the preconquest Nahuatl language, in writing of the mushrooms often referred to disconsolate, dissolute, disintegrating states of personality; the members of society using the mushrooms were "the deranged one," "the angry young man," "the noblewoman without shame," "the prostitute, the procurer, the enchanter."

This language is the sixteenth-century equivalent of the modern psychiatric approach to hallucinogens. AMA President Roy Grinker, M.D., in an editorial in the Archives of General Psychiatry, warns that "... latent psychotics are disintegrating under the influence of even a single dose; long-continued LSD experiences are subtly creating a psychopathology." Dana Farnsworth, M.D., Harvard health officer, in another editorial refers to drug-induced "nightmares" such as thinking one is only six inches tall, and "horrid, involuntary hallucinations."[12]

The pattern is the same: the representatives of the current psychological power system-the clerics then, the psychiatrists now-react to the new "detonator of the soul" with puritanical paranoia and fearful fantasies of sin, degradation, disintegration. Since anxious suspicion does not allow them to become acquainted with the real nature of the alleged demonic plant or substance, ignorant misrepresentations soon shroud any mention of them, and repressive measures are vigorously pursued.

The historian Lothar Knauth has gathered further references which shed a somewhat different light on the Aztecs' use of the mushrooms. For example, Orozco y Berra, in his account of the coronation of Motecuazoma II, says,

> The religious festivities ended, the lords gathered to eat woodland mushrooms, which contain that which confuses the mind, as if they were intoxicating drinks; while their minds were confused they saw visions, believed they heard voices; therefore they took these hallucinations as divine notices, revelations of the future, and augury of things to come[13].

Another writer, Tezozomoc, has this to add:

> ... the strangers gave them mushrooms found in the mountain woods so that they would get intoxicated, and with that they began to dance; others went inside the room to rest. Then they took the big lights of the patio and every time they started the song the strangers began to dance and to sing, and so that they should not be known they dressed themselves with false hair[14].

For another description of a mushroom ceremony among the Aztecs, Lothar Knauth draws again on a Nahuatl text preserved by Sahaga. It is part of the fiesta that the pochteque, the great merchants of the Aztec empire, gave the night before they sent their trading caravans to the distant, foreign commercial center of the Gulf and Pacific coasts.

There arrived those that were going to dance, ... and those that were going to abandon themselves. Those of the merchant leaders who were not going to dance were the strait-laced, chaste ones, who thought themselves somebody. And the old merchants met them with flowers, with tobacco, with brilliant green paper collars and bunches of quetzal feathers, glistening in the moonlight.

> Right at the beginning, as a refreshment, they ate the mushrooms. They felt with it a burn, a red-hot blown fire inside, and not from hot food they were eating. Therefore they drank hot cacao that was kept warm for the night. Thusly they ate the intoxicating mushrooms. When they had finished eating them, they danced and they cried. Meanwhile some of them felt the effect: they went inside, they sat down, with their backs against the wall. They didn't dance any more. They sat by themselves, in the same place and let their heads hang[15].

The preceding description of the festivities sounds not too unlike a modern description of a "psychedelic celebration," at, for example, the Avalon Ballroom in San Francisco.

> On Friday and Saturday nights they swarm into the Avalon and Fillmore Ballrooms ... to be bathed in constantly changing projections of liquid colors and films, to dance in the dancing light of their ecstatic costumes and faces and feelings, and to drench themselves in the saturating rock 'n' roll of the Grateful Dead. ... The whole environment, in short, is turned on and total immersion is expected[16].

The description of the Aztec mushroom celebration goes on in a more somber key as the participants apparently become involved in visions of the manner of their death. Whether these were genuine clairvoyant experiences or shared hallucinations induced by the high Suggestibility of the bemushroomed state, it is impossible to tell at this remove.

> In that stupor, some imagined they were going to die, and they cried; some were to perish in the war; some were to be eaten by wild beasts; some were to be taken prisoners of war; some were to be somebody rich, very rich; some were to buy and be owners of slaves; some were to be adulterers, were to be stoned to death; some were to be taken for thieves and be stoned to death; some were to become dissolute, were to end as drunkards; some were to drown; some were to be somebody peaceful, peacefully living to themselves and dying the same way; some were to fall from the roof and die suddenly[17].

The negative view of the mushrooms prevailed. Spanish mycophobia succeeded in stamping out the mushroom cult as a major force in Mexican culture. Only a handful of remote mountain tribes preserved the customs and rituals of what must once have been a splendid and powerful system of worship and magic. So complete was the neglect and ignorance in the Western world of this botanical aspect of Mexican religion, that in 1915 a reputable American botanist, William E. Safford, read a paper before a learned society claiming that the so-called sacred mushroom of Mexico did not exist and never had.

In 1936, the Mexican engineer Roberto J. Weitlaner became the first white man in modern times to obtain or even see the sacred mushrooms, in the tiny Oaxacan village Huautla de Jiménez. Two years later, his daughter Irmgard, her anthropologist fiancé, and two friends became the first Westerners to witness a mushroom ceremony. In the same year, the Harvard botanist Richard E. Schultes made a trip to Huautla, obtained some specimen mushrooms from informants, and sent them to the Harvard Botanical Museum, where they were identified as the species *Panaeolus campanulatus*, sphinctrinus variety. Schultes published reports on his finds, but his own work took him to the Amazon jungles to investigate the fabled caapi or yagé vine, and he did not return to Mexico. The war years intervened, and the Mexican mushroom slipped again into the shadows of history.

On June 29, 1955, Robert Gordon Wasson and, his wife, Valentina, became the first white persons in modern times to actually participate in and partake of the sacred mushroom ceremony, again in the tiny village of Huautla de Jiménez, under the wise guidance of the now famous curandera Maria Sabina. The news of their discovery became public with the publication in 1957 of Mushrooms, Russia and History, and with a May 13, 1957, article in Life. This magazine has often since that time been the first to signal, and perhaps in some "mediumistic" way to bring about, new developments in the growth of the "psychedelic movement."

The intriguing story of how Robert Gordon Wasson, a professional banker, partner and vice-president of the Morgan Guaranty Trust Company of New York, found himself ingesting the sacred mushroom on a remote Mexican mountaintop, is worth repeating in his own words:

> (My wife) was a Great Russian and, like all of her fellow countrymen, learned at her mother's knee a solid body of empirical knowledge about the common species (of mushrooms) and a love for them that are astonishing to us Americans. ... Their love of mushrooms is ... a visceral urge, a

> passion that passeth understanding. ... I, of Anglo-Saxon origin, had known nothing of mushrooms. By inheritance, I ignored them all; I rejected those repugnant fungal growths, expressions of parasitism and decay. ... Such discoveries as we have made, including the rediscovery of the religious role of the hallucinogenic mushrooms of Mexico, can be laid to our preoccupation with that cultural rift between my wife and me, between our respective peoples, between mycophilia and mycophobia ... that divide the Indo-European peoples into two camps. ... I suggest that when such traits betoken the attitudes of whole tribes or peoples, and when those traits have remained unaltered throughout recorded history, and especially when they differ from one people to another, neighboring people, then you are face to face with a phenomenon of profound cultural importance, whose primal cause is to be discovered only in the wellsprings of cultural history. ...
>
> Our method of approach was to look everywhere for references to mushrooms. We gathered the words for "mushroom" and the various species in every accessible language. We studied their etymologies.
>
> ... We were quick to discern the latent metaphors in such words.
> ... We searched for the meaning of these figures of speech. We sought mushrooms in the proverbs of Europe, in myths and mythology, in legends and fairy tales, in epics and ballads, in historical episodes, in the obscene and scabrous vocabularies that usually escape the lexicographer. ... Mushrooms are widely linked with the fly, the toad, the cock, and the thunderbolt; and so we studied these to see what associations they conveyed to our remote forebears. ...
>
> I do not recall which of us, my wife or I, first dared to put into words, back in the 40's, the surmise that our own remote ancestors, perhaps four thousand years ago, worshiped a divine mushroom. It seemed to,us that this might explain the phenomenon of mycophilia versus mycophobia, for which we found an abundance of evidence in philology and folklore. ... I remember distinctly how it came about that we embarked on our Middle American explorations. In the fall of 1952 we learned that the sixteenth-century writers, describing the Indian cultures of Mexico, had recorded that certain mushrooms played a divinatory role in the religion of the natives. Simultaneously we learned that certain pre-Columbian stone artifacts resembling mushrooms, most of them roughly a foot high, had been turning up, usually in the highlands of Guatemala, in increasing numbers. ... We spoke up, declaring that the so-called "mushroom stones" really represented mushrooms, and that they were the symbol of a religion, like the Cross in the Christian religion, or the Star of Judea, or the Crescent of the Moslems. ... This Middle American cult of a divine mushroom, this cult of "God's Flesh" ... can be traced back to about 1500 B.C. ... the earliest period in which man was in sufficient command of his technique to be able to carve stone. Thus we find a mushroom in the center of the cult with perhaps the oldest continuous history in the world. ... The cult still existed in the Sierra Mazateca, in Oaxaca. And so we went there, in 1953. ... We found a revelation, in the true meaning of that abused word, which for the Indians is an everyday feature, albeit a Holy Mystery, of their lives[18].

The Wassons made many trips to Mexico, to the different regions, studying the various aspects of the use of the mushrooms. They enlisted eminent collaborators. One of these was Professor Roger Heim, the French mycologist, Director of the Musée National d'Histoire Naturelle, who visited Mexico with the Wassons on several occasions in order to make on-the-spot studies of the sacred mushrooms. The following species of mushrooms, many of them new to science, made up the Wasson-Heim list of hallucinogenic mushrooms used in Mexico: *Cantharellaceae-Conocybe siliginoides*, growing on dead tree trunks; *Strophariaceae-Psilocybe mexicana*, a small, tawny inhabitant of wet pastures, apparently the most highly prized by the users; *Psilocybe azteconim*, called "children of the waters" by the Aztecs; *Psilocybe zapotecorum*, of marshy ground and known by the Zapotecs as "crown of thorns mushroom"; *Psilocybe caerulescens* var. *mazatecorum*, the so-called "landslide mushroom"; *Psilocybe caerulescens* var. *migripes*, which has a native name meaning "mushroom of superior reason"; and *Stropharia cubensis*[19].

While we are on the subject of botanical identities, we might mention the later work of Singer and Guzman, who in 1957 found several additional species of Psilocybe used. As noted before, Wasson disputes Puharich's assertion that *Amanita muscaria* is used at all by the Mexicans. It will be recalled that *Panaeolus sphinctrinus* was identified as one of the teonancatl mushrooms by Schultes in 1938. Hallucinogenic activity was reported for a related species, *Panaeolus papilionaceus*, found in Oxford County, Maine. A note in Science reported that unsuspecting ingestion of this mushroom by two persons resulted in visual and hallucinatory effects comparable to hashish, opium, and "mescal." The mushroom was said to be "common on cultivated land."[20] More recently, Maurice B. Walters reported hallucinogenic activity for *Pholiota spectabilis*, a mushroom unrelated to the psilocybes. It is also fairly common in North America[21]. This writer had the experience of ingesting ground-up mushrooms, which had been collected in the Denver, Colorado, City Park, whose identity the finder refused to divulge for fear that spreading this knowledge would lead to legal restrictions on the noble fungus. The effects of this mushroom were completely hallucinogenic, comparable in all ways to the effects of synthetic psilocybin, with which I was very familiar. We may expect a rich, growing harvest of psychedelic fungi (as well as higher plants) as dedicated and ingenious amateur "theobotanists" investigate the vegetable kingdom for other active species during the next fifty years or so.

Those who are inclined to dismiss Wasson's theory of mycophobia versus mycophilia need only consider the fact that hallucinogenic mushrooms grow wild and are common on the North American continent, yet have never been used for religious or psychic purposes. Our distrust of fungi makes us surround them with so many taboos that we end up, like Professor Safford, even denying their existence in other lands. The mycophilic Mexicans, on the other hand, quietly use our imports, whose value we don't even realize: Stropharia cubensis, which is hallucinogenic, was not known in preconquest Mexico, because it grows in cow dung, and cows came to the New World with the Spanish. The Indians discovered the properties of the mushroom while the whites were busy denying it existed.

Wasson's other main collaborator on the chemical aspects of the mushrooms was the renowned Albert Hofmann of the Sandoz Laboratories in Basel, whose accidental discovery of the psychedelic properties of LSD in 1943 may well be regarded by future generations as one of the turning points of Western civilization, and who has devoted much of his professional life to the extraction of the active principles of various native hallucinogens, and their subsequent synthesis. Hofmann soon identified psilocybin as the main active principle in the mushrooms, along with smaller quantities of psilocin. Psilocin is 4-hydroxydimethyltryptamine; psilocybin is the same, with an added phosphor group. Both are indole alkaloids, like LSD, and are related chemically and in activity to the neural transmitter substance serotonin. Psilocybin is probably converted to psilocin in the body. The effects of these tryptamines are roughly comparable to LSD, differing primarily in the duration of the effect, which is about half as long as LSD. Numerous studies have been done on the pharmacological and psychological effects of psilocybin. Wasson's 1962 bibliography listed a total of 362 technical and lay items;[22] since that time the number has probably passed loco. These lie outside the scope of this article.

The use of the sacred mushrooms is heavily concentrated on Oaxaca, where it is used by the Mazatecs, Chinantecs, Chatinos, Zapotecs, Mixtecs, and Mijes. In each tribe the preferred species of mushroom and the particular rituals used vary somewhat. Secrecy about the mushrooms toward foreigners is the general practice. Puharich wrote, "The first thing one learns from the Chatinos is that no one of them will publicly admit that the sacred mushroom exists, that a rite involving its use exists, or that any practitioners of the rite exist."[23] Wasson makes a great deal of the religious motivation of the curanderos. "Performing before strangers is a profanation," and "the curandero who today, for a big fee, will perform the mushroom rite for any stranger is a prostitute and a faker."[24] Yet Wasson's own original curandera, the famous Maria Sabina, does perform rituals for strangers, sometimes for a fee, sometimes not.[25] It is hard for an outsider to evaluate the motivations of a Mexican curandera. According to recent reports, there are now always a dozen or so Americans in Huautla during the mushroom season, June through August, looking for the inevitable "honghi." Some obtain the mushrooms and take them on their own. One American flipped out and tried to eat a live turkey while on such a trip, causing Maria Sabina great difficulties with local authorities. One need reach for no deeper reason than historical experience to explain the reticence of mushroom cults toward outsiders. As in America today, they have always been persecuted and vilified. Their very survival has depended to a large extent on secrecy.

We find that the mushrooms are referred to by various terms of endearment, such as los ninios, "the children," or las mujercitas, "the little women," or most romantically, "the noble princes of the waters." In some areas, the mujercitas have to be eaten along with some hombrecitos, "little men," a different species of mushroom easily identified by its virile shape. But this is consumed for ritual purposes only, since only the "little women" give the psychic effect.

Wasson has taken photographs of a young girl grinding the mushrooms (also the Ipomoea seeds or the leaves of Salvia divinorum) on a grinding stone, in a posture identical to that found on the famous Guatemalan "mushroom stones," dating back twenty-five hundred years.

Not all the tribes have curanderas as such. The Mazatecs do, and usually the curandera takes twice as many mushrooms as the other voyagers. She decides who else takes them, and her energies dominate the session. In the Mije country, on the other hand, there are no curanderas as such; most of the families know how to use the mushrooms. One person takes them alone, with another present as observer. The reasons for consulting the mushrooms are medical and divinatory: to find a diagnosis and cure for an otherwise intractable condition; to find lost objects, animals, or people; or to get advice on personal problems or some great worry.

The use of the mushrooms for purposes of divination is accepted as a matter of fact. Demonstrations of its capacity to bring about states of higher vision have been convincingly made. A double telepathic experience was reported by the psychiatrist Dr. Margaret A. Paul under the mushroom *Amanita pantherina*, a close relative of *A. muscaria*.[26] Wasson has described his own experience with Maria Sabina on his first session with the psilocybe mushroom.

> Well, the Curandera Maria Sabina asked us what the questions were that were troubling us in the afternoon before the session. We were at a loss, because we had no questions that were troubling us, we just wished to see the ceremony. But, naturally, we had to comply with her request, and I said: "We have not heard from my son who is working in Cambridge, Massachusetts, and we are worried about him (which was not true) and we would like to know how he is faring." Now for an Indian in that country this means that you are really worried about the person, and so she went to work, and in the course of the evening she told us three things about him. She said: "He's not in Cambridge." (She didn't know what Cambridge was.) "He's in your home." I wrote notes down-and it's all in my contemporary notes-she said: "He's in your home. He's not in that other place." (It seemed awfully odd that she should volunteer this - there was no reason for it, but anyway we wrote it down.) And then she said: "He has an emotional disturbance, he reaches even to tears and it's over a girl." Well, we wrote this down-we didn't know anything about it and then finally she said: "I see the Army reaching out for him, I don't know whether the Army will get him." Well, we dismissed it. We didn't think at all about it. Then I got back to New York and was busy in banking, and then I went to Europe on a banking trip, and in Geneva a cablegram reached me from my wife saying that Peter insists on enlisting, and please to cable him not to do so. Well, I sent him a cable and it was too late and he had enlisted in the Army. Then, why had he enlisted in the Army? A letter followed and I learned that he had been in terrible emotional turmoil over a girl about whom he had never spoken to us. Oh, the first thing we discovered on returning to our apartment in New York - it was in an awful turmoil-there had been a party thrown there [laughter] and the bills of the purveyors were all accumulated for the very week-end that we had had this session with Maria Sabina. And Peter made no bones about it - "Oh yes, I went down with three or four friends from Cambridge." And they had staged a party there. Then the next thing was this Army business and then the next thing was that he had been in an awful turmoil over a girl who was living in New Haven. I have no explanation for that at all.[27]

Wasson's answer, when asked if he believed in ESP, was, "I don't believe; and I don't disbelieve. It's not my line." Research on supernormal perceptual processes, as demonstrated here and in Doctor Paul's cases, is sadly lacking and definitely indicated by the evidence brought up so far.

Where a curandera is present, she carries a thread of song almost continuously throughout the session, for many hours on end, with brief intermittent rests. The words vary slightly from session to session; the melodic line stays the same. Recordings have been published of the Mazatec ceremony, and anyone can hear for himself the forces that are collected and transmitted through these chants. Mixing Christian and Indian mythology, they run the whole conceivable range of incarnations and emotions. In addition, the curandera may emit a complex percussive beat, slapping thighs, forehead, arms. "The Mazatec communicants are participants with the curandera in an extempore religious colloquy. Her utterances elicit spontaneous responses from them, responses that maintain a perfect harmony with her and with each other, building up to a quiet, swaying, antiphonal chant. In a successful ceremony this is an essential element."[28]

In considering the Mexican ritual, we cannot forget that this is what remains among a primitive, illiterate people of a practice once widespread throughout the powerful Aztec empire. The ritual does not have the integrative synthetic qualities of the American peyote ritual, though most firsthand accounts agree that, depending, no doubt, on the wisdom and experience of the curandera, it can definitely induce a total transcendent experience.

Another and complex chapter in the checkered and colorful history of the divine mushroom was initiated in August 1960, when, in a villa near Cuernavaca, Dr. Timothy Leary, a Harvard psychologist, ate seven of the mushrooms given him by a scientist from the University of Mexico. "I was whirled through an experience which could be described in many extravagant metaphors but which was above all and without question the deepest religious experience of my life."[28] The experience triggered off over the next seven years a series of events that have been amply described and debated in the popular press and that have played a central role in the reemergence on the North American continent of a religious revival using psychedelic plants and drugs as sacraments.

Etymology and Prehistory

The word "mushroom" is derived from the old French mouscheron, which in turn is based on mousse, moss. "In popular use," according to Webster, "mushroom denotes any edible variety, as opposed to the poisonous ones (toadstools)." Immediately we are back in a circle of associations of mushrooms with toads, bufotenine, the witches. Perhaps, as the Wassons argued, toadstool, like the French crapaudin, was originally the specific name of the demonic fly amanita, the German Fliegenschwamm. Flies, bugs, maggots are popular mythic embodiments of madness and possession (e.g., "la mouche luimonte à la tae"), as readers of Sartre and William Golding well know.

Another interesting line of inquiry opens up when the association of mushrooms with thunder is explored. We have already mentioned the Chukchee tale of lightning dragging his mushroom-possessed sister thunder across the floor of heaven by her foot. In ancient Greece and Rome, as well as in Mexico, it was believed that the growth of mushrooms is directly related not only to rain, but to thundery weather. Similar etymological and folkloric links can be found in japan, the Philippines, Malagasy, Tadzhikistan, and among the Maoris, where *whatitiri* means both "thunder" and "mushroom." The Mazatec Indians call the mushroom *nti si tho* and the Mije Indians *tu muh*. In both languages the word means "that which sprouts by itself," i.e., without seed. The Zapotec Indian curandero, after gathering the mushrooms, invokes the "Powers" that control the mushrooms: the Earth, God the Father, the Trinity, the "Great Lightning Bolt that bred the mushrooms," and the "Great Lightning Bolt that injected blood into the mushrooms." Does this mean that the lightning bolt, "the strength of the earth," as the curandero called it, is thought of as impregnating the earth, and their offspring is the divine mushroom, without seed? Father Sky and Mother Earth form a mythic polarity common to many American Indian tribes.

Wasson's theory is that at some preliterate stage in man's early history, the mushrooms with extraordinary powers were discovered and "served as an agent for the very fission of his soul, releasing his faculty for self-perception, as a stimulant for the imagination of the seer, the poet, the mystic. ... May not the hallucinatory mushrooms have been the most holy secret of the Mysteries?"[30]

Puharich also has argued for the existence of a cult of the divine mushroom in the early Eurasian cultures centered around the powerful Sumero-Akkadian city-states of the third millennium B.C. And in 1926 Henri Frankfort reported the discovery of an ancient Egyptian temple in Byblos (on the Mediterranean coast of Lebanon), dating back to the middle of the third millennium B.C., in which a green jasper seal was found. This seal shows a Horus priest giving two mushrooms to a supplicant. Over the mushroom is a hare, which is the sacred symbol of the Hittite god of rain, thunder, and lightning.

Such archaeological, etymological, and mythological fragments must at present be regarded as mere tiny pieces of the history of man's strange ambivalent relationship to the hallucinogenic, psychedelic plants and drugs. It may be decades before the missing pieces are placed together to give a coherent picture. For the present we cannot much improve on the poetic formulation of Wasson's Indian guide, who when asked why the mushroom was called "that which springs forth," replied:

El honguillo viene por si mismo, no se sabe de donde, como el viento que viene sin saber de donde ni porqué.

The little mushroom comes of itself, no one knows whence, like the wind that comes we know not whence nor why[31].

The Sacred Mushrooms - Rediscovery in Mexico

by

Peter T. Furst

original source: www.drugtext.org/Hallucinogens-and-Culture/chapter-seven-the-sacred-mushrooms-rediscovery-in-mexico.html

If true, surely one of the more significant developments in the study of the ritual use of plant hallucinogens in Middle America is the recent spate of reports that at least some individuals in two Maya populations in southern Mexico are employing the psychoactive mushroom *Stropharia cubensis*[1] in the context of religious ceremony, divination, or curing. The two groups for which this has been reported-but not as yet wholly confirmed by scientifically trained observers-are the Chol, who live not far from the Classic Maya ceremonial and funerary center of Palenque, Chiapas (which, like other Maya lowland sites is thought to have been built and inhabited by ChoIanspeaking Maya), and one small population of Lacandones, of whom only a few remnant groups survive today in the general area of the Usumacinta River near the border of Guatemala. Pending the necessary confirmation, the several accounts that have reached anthropologists and others in the recent past have already led to speculation that perhaps some other Maya-speaking populations may also be found to have retained - or else re-adopted - mushroom rituals that were long thought to have died out among them centuries ago.

Considering the stream of non-Indian mushroom "devotees" that descended on the Mazatec Indians of Oaxaca after their mushroom rites were publicized in the 1950's and early 1960's, perhaps all that should be said for now about the Maya situation is that some reputable scholars have become convinced over the past several years that mushrooms are being employed ritually by at least some Chol and Lacandón Maya. It is true, however, that colleagues who sought to confirm this on the spot were unable to do so in the brief time available to them. At the very least, it seems, the local informants are more reticent on the subject now than even a few years ago. Whatever the reason, the most recent efforts to obtain first-hand information have proved unavailing. The problem is further complicated by a peculiarity of *S. cubensis*: it is a dung fungus that nowadays grows typically on the dung of cattle (as it does, for example, in the grassy meadows all around Palenque). This might lead one to think that it could not be a native New World species but must have been introduced together with cattle after the conquest. Against this, however, we have the fact *S. cubensis* has not been reported in Spain or southern Europe, and, in any event, as we shall see in another chapter, there is a native ruminant whose droppings are perfectly capable of playing host to *S. cubensis* and that played an extraordinarily prominent role in the cosmology of the Maya and other Indian peoples. That animal is the deer.

The use of an hallucinogenic mushroom in Chol country was first reported by a student of M. D. Coe at Yale University (Furst, 1972a:x); the existence of what appeared to be a well-integrated complex of mushroom intoxication, for the purpose of conversing with the deities, was first published by a specialist in Classic Maya art, Merle Greene Robertson (1972), in a paper on the carved monuments of Yaxchilân, an important Maya site on the Usumacinta River. In the course of her research, Mrs. Robertson said, she learned that some Lacandón priests consumed the mushrooms in ritual seclusion, sometimes within the ruins of the smaller temple or funerary structures at Yaxchilin. The mushrooms, she was told, are prepared in specially consecrated pottery bowls that are used for no other purpose and that differ from the so-called "god pots" with anthropomorphic decorations in which incense is burned.

The Lacandones have been subjected to anthropological inquiry for many decades, and it must be emphasized that although ritual intoxication is an essential aspect of their ceremonial life, not one of these investigators witnessed, or heard of, such mushroom rites. Nonetheless, Mrs. Robertson was told by her informants that the sacred mushrooms had served as a medium of communication with the gods for "as long as the oldest" member of that particular group could remember. One cannot help but feel that such information must be taken seriously; the Indians learned long ago - with good and sufficient reason - to conceal and disguise whatever they thought might provoke the wrath or disapproval of the ecclesiastical authorities and other outsiders. Besides, with the exception of peyote, the plant hallucinogens have only recently become the focus of anthropological inquiry in the Americas and elsewhere; field workers are only just beginning to learn to ask the right questions (or better, not to ask questions at all but wait patiently for the information to come naturally, which may, and often does, take many weeks or months of living with the people and convincing them that one means no harm nor desires to change their ways). So it should perhaps not surprise us that neither A. M. Tozzer (1907), author of a classic comparative study of the Lacandones, nor other students of Maya culture considered that ritual intoxication - which has been well-described - might have involved more than just alcohol.

However much it remains to be substantiated, the reported present-day existence of mushroom use among certain Maya groups should go a long way toward settling the question of mushroom "cults" among the ancient Maya, and the reasons for its apparent disappearance from the one area of Middle America where the archaeological evidence for such a cult has been most persuasive.

As Thompson (1970) noted, the Colonial sources on the Maya, which include several useful works on herbal medicines, are silent about intoxicating mushrooms, as well as about other botanically identified psychoactive plants (with the exception of tobacco), however much the sacred mushrooms and plant hallucinogens in general fascinated their contemporaries writing in sixteenth- and seventeenth-century central Mexico. Yet it has long been known that as long as 3000 years ago at least the inhabitants of the highlands and the Pacific slope of Guatemala, as well as some of their neighbors, held certain mushrooms to be so sacred and powerful - perhaps even divine - that they represented them in great number in sculptured stone. In fact, the production of mushroom images or idols of varying symbolic complexity endured in Mesoamerica for nearly two millennia, from ca. 1000 B.C. to the end of the Classic period, ca. A.D. 900, suggesting that a cult of sacred mushrooms not only lasted thousands of years but was anciently more widespread than the sixteenth-century chronicles would lead us to believe.

"Mushroom of the Underworld"

Actually, Thompson was only partly right when he said that the Spaniards were silent on the matter of hallucinogens among the Maya, for several of the early dictionaries compiled by Spanish priests in the Guatemalan highlands demonstrate considerable Indian knowledge of the intoxicating effects of a number of mushroom species[2]. One of the oldest of the Colonial word lists, the Vico dictionary, which was apparently compiled well before the 1550's, explicitly mentions a mushroom called xibalbaj okox (xibalba = underworld, or hell, realm of the dead; okox = mushroom), with the implication that this species is hallucinogenic. In fact, in this context xibalbaj refers not just to the Maya underworld, with its nine lords and nine levels, but also to having visions thereof, so that the name can be understood to mean "mushroom which gives one visions of hell" or "of the world of the dead." The same intoxicating mushroom is also mentioned in a later word list, Fray Tomas Coto's Vocabulario de la lengua Cakchiquel, dated ca. 1690 (manuscript in the library of the American Philosophical Society, Philadelphia), which pulls together much of the earlier material on Cakchiquel-Maya. According to the Coto dictionary, xibalbaj okox, mushroom of the underworld, was also called k'aizalah okox, which can be translated as "mushroom that makes one lose one's judgment."

The Coto dictionary also describes a mushroom called k'ekc'un, which inebriates or makes drunk, and another, muxan okox, "mushroom that makes the eater crazy" (from mox, meaning "mushroom" in the Mixe-Zoque languages of southern Mexico, and "crazy," or "falling into a swoon," in Cakchiquel-Maya of the Guatemalan highlands). Lyle Campbell (personal communication) and Terrence Kaufman, two linguists who have recently investigated the problem of linguistic diffusion in Mesoamerica, believe muxan okox to be one of several cases of linguistic borrowing of ritual terms from Mixe-Zoque into Maya languages in ancient times, perhaps as early as 1000 B.C., or even before. Since they also postulate Mixe-Zoque as the language of the Olmecs - the "mother culture" of Mesoamerican civilization - it is tempting to suggest that the Olmecs might have been instrumental in the spread of mushroom cults throughout Mesoamerica, as they seem to have been of other significant aspects of early Mexican civilization.

Mushroom Stones and the Cult of Sacred Mushrooms

Mention in several of the early sources on Guatemalan Maya languages of a mushroom specifically named for the underworld - i.e. the realm of the dead - is especially interesting in light of the discovery of a ceremonial cache of nine beautifully sculptured miniature mushroom stones and nine miniature metates (grinding stones),dating back some 2200 years, in a richly furnished tomb at Kaminaljáyu, a late Preclassic and Early Classic archaeological site near Guatemala City. The coincidence of the number of mushroom effigy sculptures interred with a Maya dignitary and the number of rulers of the traditional Maya underworld immediately impressed archaeologist Stephan de Borhegyi (1961), who proposed that the mushroom idols were almost certainly connected with the Nine Lords of Xibalba, as described in the Popol Vuh, the sacred book of the Quiche-Maya.

Stone effigies of mushrooms have in fact been turning up in archaeological contexts in Guatemala and Mexico since the nineteenth century. Borhegyi, who until his untimely accidental death in 1969 was director of the Public Museum of Milwaukee, Wisconsin, described, classified, and tentatively dated some 50 of these. More recently, a botanist, Bernard Lowy (1971), augmented the list with another 50, mainly from the highlands and Pacific slope of Guatemala. At this writing, Richard M. Rose, an anthropologist working on a classification of all known mushroom effigies, has catalogued more than 200, many dating to the first millennium B.C. The majority were found on Guatemalan soil, but others come from as far south as El Salvador and Honduras, and as far north as Veracruz and Guerrero in Mexico. Unfortunately, with a few notable exceptions, such as the nine miniature sculptures from Kaminaljóyu, the majority of these interesting effigies was not recovered under scientifically controlled conditions, so that reliable information on provenance and context is not usually available (Richard M. Rose, personal communication).

Connection between these sculptures and the historic mushroom cults of Mesoamerica has not always been accepted. Though many mushroom stones are quite faithful to nature, they were, until recently, not even universally thought to represent mushrooms at all, and a few diehards even now, in the face of all the evidence, reject this interpretation. When first reported in the nineteenth century, the sculptures were thought to be phallic symbols only, a theory that still crops up occasionally but that must be rejected as one-sidedly male-centered. To have any validity at all, the phallic element would have to be seen as one half of a male-female unity, in that the arrangement or juxtaposition of stem (male) and cap (female) in the mushroom fits well into the traditional Mesoamerican system of complementary opposites and the synthesis of male and female elements as the essential precondition for fertility and fecundity. (It is this concept that is expressed so well in Mesoamerican cosmology in the merging of a primordial male and female pair of creator gods into a single bisexual being.)

It was Carl Sapper who in 1898 first identified archaeological mushroom stones from Guatemala and El Salvador as idols of deities in the shape of mushrooms, rejecting, on obvious morphological grounds, the notion that they had served as phallic symbols in a fertility cult. Even now one hears it said that perhaps they were used as seats, or as territorial markers, or even that they might have been potter's tools that served for the making of molds for ceramic bowls. Of these, only for the marker opinion could one make some kind of argument - but even if a mushroom idol served anciently to mark the boundary of a community's land holdings, which in any event were considered sacred, it could have done so as idol of a guardian deity rather than as a property marker in the modern sense. In any case, refusal to recognize the sculptures as what they obviously are - mushroom idols - is likely to be a function of R. G. Wasson's ingenious division of people into those who loathe mushrooms and those who like them (or, in his terminology, mycophobes and mycophiles), a dichotomy that he relates to the history of sacred mushrooms in the lives of different populations since remote antiquity. Even without the visual evidence, one would have to explain away the fact that many of these sculptures, especially those that date between 1000 and 100 B.C., not only represent a naturalistic mushroom but also incorporate a human face or figure, or some mythic or real animal - toads and jaguars in particular - that merge with or project from the stem. The jaguar-mushroom association is especially interesting in light of the mention, in the Coto dictionary, of a mushroom called "jaguar ear." One of the most intriguing of these mushroom "idols" depicts the fungus emerging from the upturned mouth of a toad, apparently *Bufo marinus*, the venomous amphibian that in much of Middle America, and also in the South American tropics, stands for the divine earth as Mother Goddess in her monstrous, devouring animal manifestation (e.g. Tlaltecuhtli, "Owner of the Earth," the earth monster in Aztec cosmology, or Toad Mother Eaua Quinahi, also meaning Owner or Guardian of the Earth, of the Tacana Indians of Amazonian Bolivia [Furst, 1972b].) Wasson (1967a), in his previously quoted discussion of the crucial role of the doncella, or maiden, in the preparation of ritual hallucinogens, has drawn attention to another interesting synthesis of naturalistic and symbolic elements in a mushroom stone in a New York collection:

The cap of the mushroom carries the grooved ring that according to Stephan F. de Borhegyi is the hallmark of the early pre-Classier] period, perhaps B.C. 1000. The stone comes from the Highlands of Guatemala. Out of the stipe there leans forward a strong, eager, sensitive face, bending over an inclined plane. It was not until we had seen the doncella leaning over a metate and grinding the sacred mushrooms in Juxtlahuaca in 1960, that the explanation of the Namuth artifact came to us. The inclined plane in front of the leaning human figure must be a metate. It follows that the face must be that of a woman. Dr. Borhegyi and I went to see the artifact once more: it was a woman! A young woman, for hr breasts were only budding, a doncella. How exciting it is to make such a discovery as this: a theme that we find in the contemporary Mixteca, and in the Sierra Mazateca, and in the Zapotec country, is precisely the same as we find recorded in Jacinto de la Serna and in the records of the Santo Oficio. (p. 348)

Was the Fly-Agaric Sacred to the Maya?

Mushroom effigies of fired clay have also been found in Mexico, as well as South America. Wasson himself has in his collection a fine terracotta "mushroom priestess" in the Classic Veracruz style, probably from the middle of the first millennium A.D., and I have been able to identify a number of ceramic mushroom depictions in the 2000-year-old tomb art of western Mexico (Furst, 1973, 1974c).

Before we leave the archaeological evidence from Mesoamerica, there is one intriguing point to be made about the probable taxonomy of the various mushroom representations. The morphology of the west Mexican ones leaves little doubt that a species of *Psilocybe* is meant. Some of the clay effigies even emphasize the characteristic knob or bump in the center of the cap. Oddly enough, however - considering that there is no evidence that the genus Amanita was ever employed hallucinogenically in Mesoamerica - some Guatemalan mushroom stones seem less to resemble *Psilocybe* than *Amanita muscaria*, the fly-agaric of Siberian shamanism, which also grows in highland Guatemala and elsewhere in North America. On the other hand, the fact that the stem or stipe of the mushroom stones is usually thick like that of *A. muscaria*, and not spindly like that of Psilocybe, might be a function only of the sculptor's material, especially where the stipe is combined with a human or animal effigy. Perhaps there were formerly also wooden mushroom idols that more closely approximated the characteristics of *Stropharia* or *Psilocybe* mushrooms. In any event, the Quiche-Maya of the Guatemalan highlands are evidently well aware that *A. muscaria* is no ordinary mushroom but relates to the supernatural, what with the fact that they have named it cakuljá ikox (cakulja = lightning, ikox = mushroom) (Lowy, 1974, 188-l91). *A. muscaria* is thus related to the Quiche-Maya Lord of Lightning, Rajaw Cakulja, who also directs the dwarflike rain bringers, called chacs in former times but now generally Christianized (in name, not function) as angelitos, little angels.

The ceramic art of the Moche civilization of Peru (ca. 400 B.C.-A.D. 500) also includes a number of anthropomorphic mushroom effigies, as well as personages with mushroom headdresses, dating to the first centuries A.D. Even more interesting is a certain class of spectacular pendants of cast gold from northern Colombia and Panama, apparently representing a deity. Most are highly stylized, but they share one feture - a pair of hemispheric headdress ornaments that look vaguely like bells on an old-fashioned telephone. These had long mystified specialists in the prehistoric art of the region until Andre Emmerich (1965) published a convincing argument that they were pairs of mushrooms that had undergone a stylistic evolution from near-naturalism in earlier pieces to greater stylization, including loss of the stem, in the later ones. Paired mushroomlike head ornaments in fact also occur to the north, on archaeological figurines found in Jalisco, western Mexico. Little is known of pre-Hispanic mushroom use in South America, with the single exception of an early Jesuit report from Peru that the Yurimagua Indians, who have since become extinct, intoxicated themselves with a mushroom that was vaguely described as a "tree fungus."

It is fitting, in the developing story of the Mexican mushrooms, that recognition be given especially to the contribution of that scholarly amateur (in the original complimentary meaning of the word), R. Gordon Wasson. It was he and his late wife, Valentina P. Wasson, who in the mid-1950's rediscovered the living mushroom cult of Oaxacan Indians and brought it to the attention of the world, not only in the pages of Life and in scientific journals but in a remarkable book, Mushrooms, Russia and History (1957). In its pages Borhegyi and Wasson suggested a connection between the sacred mushrooms of Mexico and the prehistoric stone mushrooms of Guatemala - the first time that such a possibility had been considered in print. But this takes us slightly ahead of our story, which should properly begin in the sixteenth century when Sahaglin first described slender-stemmed hallucinogenic mushrooms with small round heads that the Aztecs called teonanacatl, flesh or food of the gods, which he said were usually taken with honey (as the Lacandón are also said to take them), and which could have either pleasant or frightening effects. Francisco Hernandez (1651) was more specific; he mentioned three different kinds of intoxicating mushrooms that were revered by the people of central Mexico at the time of the Conquest. In the seventeenth century Jacinto de la Sema and Ruiz de Alarcón were still perturbed by the continued survival of such mushrooms in indigenous ritual, but thereafter they pass out of the literature, without a single one having been identified botanically - so much ignored that the economic botanist Safford (1915) decided they had never existed at all and that teonanácatl must have been peyote!

Safford's ethnocentric verdict came to be widely accepted although it flew in the face of some very specific historic references (e.g. Sahagtin: "It grows on the plains, in the grass. The head is small and round, the stem long and slender" - a description that hardly fits the peyote cactus, which occurs only in the semi-arid northern high desert. One who disagreed was the aforementioned Dr. Reko, who insisted that the old sources were accurate and that the use of hallucinogenic mushrooms had in fact survived in remote mountain villages of Oaxaca.

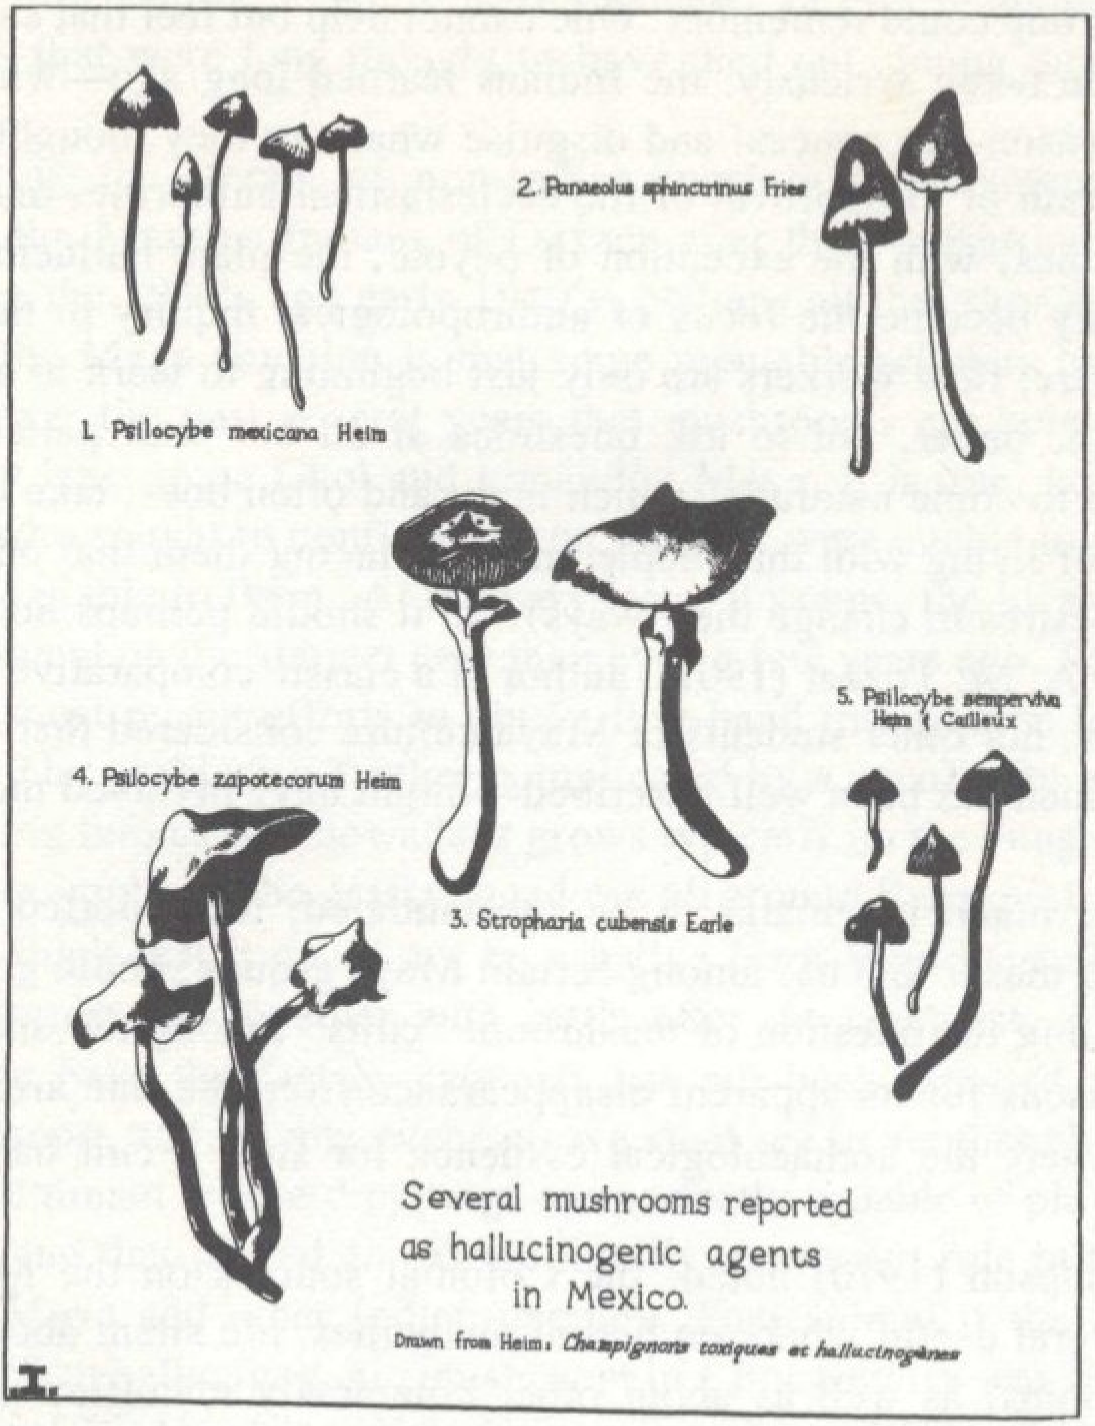
Found at Last: A Living Mushroom Cult in Mexico

He was to be proved right in the late 1930's. In 1936 "Papa" Weitlaner encountered magic mushrooms for the first time in the country of the Mazatecs in Oaxaca. He sent a specimen to Reko, who forwarded it to the Harvard Botanical Museum, where unfortunately it arrived too badly deteriorated to be identified. In 1938, Weitlaner, his daughter Irmgard, and her future husband Jean Basset Johnson, on a field trip to Huautla de Jimenez became the first outsiders permitted to attend - though not participate in - an all-night curing ritual in which mushrooms were eaten. Johnson, who lost his life in North Africa in 1944, described the experience at a meeting of the Sociedad Mexicana de Antropologia in August 1938 and in a more extensive paper published by the Gothenburg Ethnographical Museum (1939).

Mushroom use, he wrote, appeared to be widespread in Mazatec country; shamans, or curers, used them primarily for the purpose of divining the cause of an illness, and during the session it was the mushrooms, which were held in great reverence, that were believed to speak, not the curer. Johnson also confirmed that not just one but several kinds of intoxicating mushrooms were known to the Indians.

In August 1938, a month after the Weitlaner-Johnson experience at Huautla de Jimenez, Schultes and Reko received from Indian informants in the same village specimens of three different species they were told were revered by the people for their visionary properties. Schultes took careful notes of their morphology and in 1939 published the first scientific description. In 1956, the distinguished French mycologist Roger Heim, director of the Museum d'Histoire NatureIle in Paris, identified one as Psilocybe caerulescens; another was defined by the Harvard mycologist Dr. David Linder as *Panaeolus campanulatus*, subsequently redefined as *P. sphinctrinus*; and the third by Dr. Rolf Singer as *Stropharia cubensis*.

Schultes and Reko on their field trip in 1938 had also been able to extend the area of sacred mushroom use beyond the frontiers of Mazatec country to other Indian groups of southeastern Mexico. In the years since, more mushroom-using populations have been added to the list, including, as recently as 1970-l971, the Matlatzinca of San Francisco Oxtotilpan, a small town located about 25 miles southeast of Toluca in the state of Mexico, and possibly also the Chol and Lacandón in the Maya lowlands. The Matlatzinca, who belong to one of the oldest language families of Mexico, the Otomian, are the first inhabitants of central Mexico to have been identified with mushroom use since the sixteenth and seventeenth century, and the Chol and Lacandon are, as already noted, the very first Maya populations for whom sacred mushrooms have been reported in historic times. Altogether we now know of about fifteen different Indian groups, each with its own language, whose curers employ hallucinogenic mushrooms. There are likely to be still others, including lowland and perhaps even highland Maya-speakers, among whom the ancient practice will eventually be found to have survived.



1. Psilocybe mexicana Heim
2. Panaeolus sphinctrinus Fries
3. Stropharia cubensis Earle
4. Psilocybe zapotecorum Heim
5. Psilocybe semperviva Heim & Cailleux

Several mushrooms reported as hallucinogenic agents in Mexico.

"Mycophiles" and "Mycophobes"

In the meantime Mexican mushroom research had entered an entirely new and more public phase with the entry of the Wassons into the picture. Wasson was a banker, a vice president of J. P. Morgan & Co. in New York; his wife, Valentina Pavlovna (who died in 1958), was a Russian-born pediatrician. Wasson has often told the story of their deep personal stake in mushroom research, which received its initial impetus with his discovery, on their honeymoon, that he and she had assimilated from their different parental cultures very different - indeed, diametrically opposed - points of view toward mushrooms in general, and wild ones in particular:

A little thing, some will say, this difference in emotional attitude toward wild mushrooms. Yet my wife and I did not think so, and we devoted a part of our leisure hours for more than thirty years to dissecting it, defining it, and tracing it to its origin. Such discoveries as we have made, including the rediscovery of the religious role of the hallucinogenic mushrooms of Mexico, can be laid to our preoccupation with that cultural rift between my wife and me, between our respective peoples, between mycophilia and mycophobia (words we devised for the two attitudes), that divide the Indo-European peoples into two camps. (1972a:186)

In 1952, the Wassons first learned of the early Colonial descriptions of mushroom rites and their confirmation by Schultes and others in the late 1930's, and, simultaneously, of the remarkable archaeological artifacts called mushroom stones. In 1953 they plunged seriously into the problem, spurred on by a lengthy description of Mazatec mushroom practices they received from Miss Eunice Pike, a missionary linguist with the Wycliffe Bible Translators, who had spent several years among the Indians of Oaxaca. (See Pike and Cowan, 1939.) Belief in the sacred mushrooms was indeed widespread, she confirmed, but the Indians guarded their secrets well against strangers. As Johnson had reported in 1939, she wrote that pre-Christian and Christian religious concepts and terminologies were inextricably intermingled in the Oaxacan mushroom rites (as, indeed, they are everywhere else, with the exception of the Lacandón; Huichol peyote ritual is likewise essentially non-Christian in meaning and terminology). For example, the Mazatecs spoke of the mushrooms as the blood of Christ, because they were believed to grow only where a drop of Christ's blood had touched the earth; according to another tradition, the sacred mushrooms sprouted where a drop of Christ's spittle had moistened the earth and because of this it was Jesucristo himself that spoke and acted through the mushrooms. (Hofmann, 1964)[3]

"A Soul-Shattering Happening"

In 1953 the Wassons went to Oaxaca for the first time, but another two years passed before they were able to develop a sufficiently warm bond of trust with their Indian hosts to be permitted to partake of the sacred mushrooms. So, in 1955, Wasson and a companion, Alan Richardson, became the first outsiders to actually participate in a mushroom curing ceremony - an unforgettable experience, Wasson later reported, that was to profoundly affect him, who by his cultural inheritance had once utterly "rejected those repugnant fungal growths, manifestations of parasitism and decay" (1972a: 185).

In his enthusiasm for the extraordinary psychic effects of the mushrooms and other sacred halluginogens, Wasson would not be misunderstood as suggesting that these are, or were, the only means of attaining the ecstatic state. Clearly, poets, prophets, mystics, and ascetics ... seem to have enjoyed ecstatic visions that answer the requirements of the ancient Mysteries and that duplicate the mushroom agape of Mexico. I do not suggest that St. John of Patmos ate mushrooms in order to write the Book of the Revelation. Yet the succession of images in his vision, so clearly seen and yet such a phantasmagoria, means for me that he was in the same state as one bemushroomed. (1972a:196)

Nor would he suggest that Blake had to have taken mushrooms or some other natural hallucinogen in order to write that "he who does not imagine in stronger and better lineaments, and in stronger and better light than his perishing eye can see, does not imagine at all." Nevertheless, ... the advantage of the mushroom is that it puts many (if not all) within reach of this state without having to suffer the mortifications of Blake and St.

John. It permits you to see, more clearly than our perishing mortal eye can see, vistas beyond the horizons of this life, to travel backward and forward in time, to enter other planes of existence, even (as the Indians say) to know God. ... All that you see during this night has a pristine quality: the landscape, the edifices, the carvings, the animals - they look as though they had come straight from the Maker's workshop. (1972a:197-198)[4]

Wasson came away from what he later characterized as a profoundly soul-shattering happening, convinced that the magical powers the Indians had ascribed since ancient times to their revered mushrooms were very real indeed, and that chemistry alone could never fully account for the experience of an ineffable mystery, akin to those of the ancient Greeks, with the simultaneous participation of all the senses:

... the bemushroomed person is poised in space, a disembodied eye, invisible, incorporeal, seeing but not seen. In truth, he is the five senses disembodied, all of them keyed to the height of sensitivity and awareness, all of them blending into one another most strangely, until, utterly passive, he becomes a pure receptor, infinitely delicate, of sensations. (p. 198)

The Mosaic Completed

Nevertheless, Wasson was sufficiently a child of the scientific age not to leave it at that (he is, in fact, a meticulous and 'critical scholar and tireless researcher, as demonstrated by his extraordinary book on the identity of Soma [1968] and his latest work, the first definitive monograph on an Oaxacan mushroom rite [1974]). Even before his Mazatec mushroom experience he was in close contact with Roger Heim as one of the leading mycologists in the western world, and Heim now accompanied him on further expeditions into the mountains of Oaxaca, in consequence of which a dozen or so different mushrooms of the family Strophariaceae, mostly of the genus *Psilocybe*, but also of *Conocybe* and *Stropharia*, were identified. With the additional field work of Singer (1958) and the Mexican botanist Gastón Guzman-Huerta (1959a, b), by the end of the 1950's the mosaic of the sacred mushrooms of Mexico, completely unknown only twenty years earlier, was reasonably complete.

According to Schultes's summary of 1972, and his and Hofmann's collaborative monograph on the plant hallucinogens (1973), species of Psilocybe and Stropharia are the Most important, the most significant being apparently *Psilocybe mexicana* , *P. caerulescens* var. *mazatecorum* , *P. caerulescens* var. *nigripes* , *P. yungensis* ,[5] *P. mixaeensis*, *P. hoogshagenii*, *P. aztecorum*, *P. muliercula*, and *Stropharia cubensis*. Singer (1958) reported that his own work in Oaxaca failed to find *Panaeolus sphinctrinus* - one of the three hallucinogenic species the Indians gave Schultes and Reko in 1938-in the Mazatec inventory of sacred mushrooms. But as Schultes (1972a) points out, different shamans have their own favorite species and also tend to vary these according to seasonal availability and the precise purpose for which the mushroom is intended. *Psilocybe mexicana*, a small, tawny inhabitant of wet pasture lands, he writes, is probably the most important species utilized hallucinogenically in Mexico, but the strongest psychedelic effects seem to belong to Stropharia cubensis.

Heim was able to propagate a laboratory culture of the sacred mushrooms in Paris, but when attempts to isolate the active principles of Psilocybe mexicana proved unsuccessful, he submitted several specimens, as well as other species, to Hofmann for analysis at Sandoz. Hofmann was almost immediately successful in discovering the agents responsible for the extraordinary psychic effects of the mushrooms, and, shortly afterwards, in reproducing the chemicals synthetically without the aid of the plants themselves. The principal active agent was identified to be an acidic phosphoric acid ester of 4-hydroxydimethyltryptamine, allied to other naturally occurring organic compounds such as bufotenine and serotonin, and probably derived biogenetically from tryptophane. This he named psilocybine. Also present as an unstable derivative was a compound he called psilocine. The same constituents have been isolated from several North American and European mushroom species that are not used as hallucinogens and for which we have no indication that they were ever so employed (Schultes, 1972a:10).

The active agents of the sacred mushrooms, Hofmann reported, amount to about 0.03% of the total weight of the plants; to achieve the effect of as many as 30 mushrooms (only a few are actually used at a time in the rite) would require only 0.01 gram of the crystallized powder dissolved in water.

Hofmann (1964) has summarized the most important results of the phytochemical investigation of the sacred mushrooms as follows: Psilocybine and psilocine are chemically-structurally related to serotonin, a substance that occurs in the mammalian brain and that plays a role in the chemistry of brain function. The structural relationship of the active principles of the mushrooms with serotonin provides an explanation for their psychic effects, and offers insights into the biochemistry of the brain itself. The pharmacological phenomena are explainable in terms of central excitation of the sympathetic nervous system. In human subjects, doses of 6 to 20 milligrams bring about, without any physical symptoms worth mentioning, fundamental changes or transformations of consciousness, with wholly different perceptions of space, time, and one's psychic and bodily self. The sense of sight and also that of hearing are greatly heightened, to the point of visions and hallucinations. Not uncommonly, long-forgotten events, often those that belong to the realm of earliest childhood, manifest themselves with extraordinary clarity.

Although he was by no means finished with the phytochemistry of the mushrooms (for example, he himself, in the company of Wasson, was still to experience their wondrous mystical effects in a mushroom rite conducted by the famous Mazatec curing priestess Maria Sabina [Wasson et al. , 1974]), for Hofmann the stage was now set for his discovery in the divine morning glories of lysergic acid derivatives closely related to LSD-just as the synthethis of LSD in 1943 had led to the isolation of psilocybine and psilocine in the sacred mushrooms.

References:

1. Although the species name appears to identify this psychedelic mushroom with Cuba, it should not be taken to mean that it is, or originally was, native only to that island or the Caribbean in general. Rather, it was so designated because it was first described in 1906 by F. S. Earle after encountering it in Cuba. S. cubensis appears to be a New World variety found mainly - but not exclusively - in Mexico and parts of Guatemala; interestingly enough, a similar species, originally called Naematoloma caerulescens but subsequently assigned to the same genus as S. cubensis, was identified in 1907 in what is now North Vietnam. For the most recent discussion of the Psilocybin mushrooms, including S. cubensis, see Steven Hayden Pollock, M.D., "The Psilocybin Mushroom Pandemic," Journal of Psychedelic Drugs, Vol. 7, No. 1, pp. 73-84 (1975).
2. My colleague Robert M. Carmack, one of the most knowledgeable of scholars in the field of highland Guatemalan ethnohistory and culture, to whom I am indebted for the mushroom references in early highland dictionaries, recently collected mushroom lore from a Quicheanspeaking elder, confirming that some of the ancient knowledge continues to survive.
3. According to current terminology for the cultural phases of Mesoamerican prehistory this should be called Middle Formative. The dating is in any event only approximate.
4. This belief seems to have its origin in indigenous shamanism. In Mexico, as everywhere else in shamanistic religion, supernatural and therapeutic power are attributed to the shaman's spittle, which is sometimes identified (as among the Papago of Arizona) as rock crystals in liquid form, rock crystals being near-universally regarded as crystallized spirits, usually of deceased shamans. Divine spittle is also related to the origin of the sacred mushroom in Siberia (see Chapter Eight).
5. It is typical of the syncretistic nature of the present-day mushroom cult that some Oaxacan Indians say God gave them the sacred mushrooms because they could not read and it was necessary for him to speak to them directly through the mushrooms. Eunice Pike and her fellow missionary Florence Cowan (Pike and Cowan, 1959) have related how difficult it is to explain the Christian message to people who are convinced they already possess the means - the sacred mushrooms - to receive the word of God in immediate and vivid form, to visit heaven for themselves, and to establish direct contact with God. Readers interested in other sensitive accounts of the mushroom experience might consult, apart from Wasson's most recent work (1974), Henry Munn's essay in Hamer (1973).
6. Schultes suggests that this might have been the species employed by the Yurimagua Indians of Peru.

Using Psychedelics Wisely

My wife Jean and I had driven several miles up the mountain to an elevation of 6000 feet a few miles south of Mount Whitney in California. We were about to meet Franklin Merrell-Wolff, author of the book *Pathways through to Space*, an impressively articulate and detailed description of a person entering a state of enlightenment and savoring it over several months.

When we were ushered into his private office, we found ourselves before an outstanding personage who radiated a marvelous glow. When we had talked for a few minutes and I felt sufficiently at home, I spoke of our research work, telling him that we had spent three and a half years administering LSD, sometimes in conjunction with mescaline, to 350 research subjects and had published our findings in medical journals.

"My oh my!" he said, looking at us with consternation. "I hope you haven't used these drugs yourselves."

We admitted that we had. He continued, "According to X" (here he mentioned an Indian sage whose name I do not remember), "it will take you seven incarnations to recover from the damage of taking such substances!"

Naturally I was upset, but I didn't think of the appropriate reply until we were driving back down the hill: "Never underestimate the grace of God!"

There is no question that psychedelic substances are remarkable graces. The farther one can reach into the vastness to be explored, the more one realizes how powerful these materials are. There seems to be no end to the levels of awareness that can be realized by those who use them to explore their psyches with integrity and courage.

The great value in these chemicals is that, in some way still not scientifically explained, they dissolve the boundaries to the unconscious mind. They give us access to our repressed and forgotten material, to the Shadow that C.G. Jung so effectively dealt with, to the archetypes of humanity, to an enormous range of levels of thought, and to the wellspring of creativity and mystical experience that Jung called the collective unconscious.

At the heart of the unconscious is what many experience as the source of life itself, and which some call God. Those who have experienced this describe it as a wondrous, ineffable source of light and energy that infuses all of creation, embracing all wisdom and radiating a vast, unending, and ever-constant love. Immersion in this is the essence of the mystical experience and produces what the great mystics have described as the state of unity or oneness. Such union is the culmination of all seeking, all desire; it is the most cherished of all experiences of which man is capable.

Not all who ingest these substances can count on such revelations. In fact, psychedelics are powerful agents and can be misused. It must be remembered that they help reveal the unconscious, and most of us have made its contents unconscious for very specific reasons. We may not welcome the appearance of repressed, painful feelings, or of evidence that our values and lifestyles might be considerably improved. Nor is it always easy to accept the spaciousness of our being, our immense potential, and the responsibility that these entail. We may also refuse to believe that we are entitled to so much beauty and joy without paying any price other than being ourselves!

To assure a rewarding outcome, let's look at some factors that should be taken into consideration when using these materials. I must add here that in no way am I encouraging the use of illegal substances. I do hope, however, that greater understanding of these materials will help restore an intelligent policy that will make further research possible. Here are some things that will help ensure beneficial results:

Set and setting

Set and setting have been widely recognized as the two most important factors in undertaking a psychedelic experience. Of these, set has the greatest influence.

As the drug opens the door to the unconscious, huge spectrums of possibilities of experience present themselves. Just how one steers through this vast maze depends mostly upon set. Set includes the contents of the personal unconscious, which is essentially the record of all one's life experience. It also includes one's walls of conditioning, which determine the freedom with which one can move through various vistas. Another important aspect of set consists of one's values, attitudes, and aspirations. These will influence the direction of attention and determine how one will deal with the psychic material encountered.

In fact, one can learn a great deal by accepting and reconciling oneself with uncomfortable material. Resisting this discomfort, on the other hand, can greatly intensify the level of pain, leading to disturbing, unsatisfactory experiences, or even psychotic attempts at escape. This latter dynamic is largely responsible for the medical profession's view of these materials as psychotomimetic. On the other hand, surrender, acceptance, gratitude, and appreciation can result in continual opening, expansion, and fulfillment.

Setting, or the environment in which the experience takes place, can also greatly influence the experience, since subjects are often very suggestible under psychedelics. Inspiring ritual, a beautiful natural setting, stimulating artwork, and interesting objects to examine can focus one's attention on rewarding areas. Most important of all is an experienced, compassionate guide who is very familiar with the process. His mere presence establishes a stable energy field that helps the subject remain centered. The guide can be very helpful should the subject get stuck in uncomfortable places, and can ask intelligent questions that will help resolve difficulties, as well as suggesting fruitful directions of exploration that the subject might have otherwise overlooked. The user will also find that simply sharing what is happening with an understanding listener will produce greater clarity and comfort. Finally, a good companion knows that the best guide is one's own inner being, which should not be interfered with unless help is genuinely needed and sought.

Motivation

This is extremely important. Those who earnestly seek knowledge and deeply appreciate life in all its forms will do well. Yet certain characteristics of psychedelics make them very popular for recreational use. The most attractive of these is their great enhancement of sensual responses, which offer heightened perception, amplification of beauty and meaning, and intensified sensual gratification. Psychedelics can also generate a great sense of closeness among participants, especially in a group setting. While I am convinced that one of the great cosmic commands is "Enjoy," there are traps in using these substances purely for recreation. The first is that a person seeking the delights of the senses may find himself overwhelmed by the eruption of repressed unconscious material without knowing how to deal with it. Another danger is that constant pleasure-seeking without giving anything back to life can distort the personality and ultimately produce more discomfort. The safe, sure way to rewarding outcomes with psychedelics is through intelligent, well-informed use.

Honesty

For the serious spiritual seeker, or for that matter anyone seeking knowledge, the single most important characteristic is honesty. This means the courage to look at whatever is presented by the deep mind, the ability to admit one's shortcomings when they become apparent, and the determination to change one's behavior in line with the truth one has experienced.

Ongoing discipline

Experts in the field now generally agree that it is wise to conduct psychedelic explorations within the framework of a spiritual discipline or growth program that will continually call attention to fundamental values and goals. A good discipline will outline a body of ethics for personal behavior that will support the changes required. Good ethics will also help us stay clear about our objectives, and will keep the door open to increasing depths of experience. Moreover, there is evidence to suggest that the more we are prepared to pass on to others whatever spiritual largess we have accumulated, the more we will be given.

For myself, I found training in Tibetan Buddhist meditation a potent adjunct to psychedelic exploration. In learning to hold my mind empty, I became aware that other levels of reality would more readily manifest. It was only in absolute stillness, accompanied by a special, highly developed quality of listening, that many subtle but extremely valuable nuances of reality appeared. While I achieved this to some extent in ordinary practice, I found this effect to be greatly amplified while under the influence of a psychedelic substance. This in turn intensified my daily meditation practice.

Psychedelics as way-showers

The role of psychedelics is often misunderstood. Many feel that having had wonderful experiences, they now have the answers and are somehow changed. And no doubt in many respects they are. But users often overlook the fact that there are usually heavy walls of conditioning and ignorance separating the surface mind from the core of our being. It is a blessing that psychedelics can set aside these barriers and give access to our real Self. But unless one is committed to the changes indicated, old habits of personality can rapidly reestablish themselves.

At this point many feel that repeating the experience will maintain the exalted state. It may, but most often real change requires hard work and dedicated effort. Unfortunately this is not always clear during the experience itself; it has merely pointed the way and shown what is possible. If we like what we see, it is now up to us to bring about the changes indicated.

There is a grace period following profound psychedelic experiences when changes can be rapidly made. At this time one is infused with the wonder and power of the new information. Moreover--and this is an area where some valuable research can be done--the drug experience releases a great deal of bodily and psychic armoring that is tied to our neuroses. This rejuvenation is quite noticeable after a good psychedelic experience, when, without the dragging weight of physical habit patterns, behavior can be more readily changed.

On the other hand, if you make no effort to change, old habits rapidly reassert themselves, and you find yourself sliding back into your previous state. In fact, it can be worse than before, because now you know that things can be better and are disappointed to find yourself mucking around in the same old garbage.

Another factor makes this process even more uncomfortable. A lot of the energy formerly tied up in repressed material is now released. This energy may be used quite fruitfully to expand the boundaries of your being to the new dimensions you have experienced. But if you return to old patterns of behavior, you now have more energy to reinforce them, making life more difficult. For this reason, these experiences must not be taken lightly, but with serious intent.

Dealing with the shadow

As Jung indicated, the Shadow holds all the material that we have pushed aside so we can hide from ourselves. Unfortunately, it also contains much of our energy, and as long as it is unconscious, it exerts a powerful influence on our behavior without our knowing it. Furthermore, Shadow material is responsible for most of the difficulties humans create in the world. We project our Shadow onto others, believe those others to be the source of our difficulties, and seek refuge from them rather than taking responsibility in our own hands. Consequently we must resolve Shadow material if we are to develop. If this were accomplished on a widespread basis, it would be a major benefit for the world.

Jung describes human development as the process of "making the unconscious conscious." Psychedelics, particularly in low doses, can be an extremely effective tool in this process. The bulk of my experience is with the phenethylamine compounds, which remained legal longer than the standard psychedelics such as LSD, mescaline, and psilocybin. Whereas a full dose of a phenethylamine like 2C-T-2 or 2C-T-7 might be 20 milligrams, a low dose would be ten or twelve milligrams, or roughly equivalent to 25-50 micrograms of LSD.

The most infallible guide to Shadow material is our uncomfortable feelings. Many do not like to use low doses because these feelings come to the surface. Rather than experience them, they use larger doses to transcend them. But these uncomfortable feelings are precisely what we must resolve to free ourselves from the Shadow, gain strength and energy, and function more comfortably and competently in the world. By using smaller amounts and being willing to focus our full attention on whatever feelings arise and breathe through them, we find that these feelings eventually dissolve, often with fresh insight and understanding of our personal dynamics. The release of such material permits an expansion of awareness and energy. If we work persistently to clear away repressed areas, we can enter the same sublime states that are available with larger doses--with an important additional gain. Having resolved our uncomfortable feelings, we are in a much better position to maintain a high state of clarity and functioning in day-to-day life.

I would also like to add a word about frequency: Individuals vary greatly in their frequency of use of these materials. Some are satisfied with an overwhelming experience which they feel is good for a lifetime. Others wish to renew their acquaintance with these areas once or twice a year. Still others are interested in frequent explorations to continually push their knowledge forward. Regardless of the frequency, it is wise to make sure that the previous experience has been well integrated before embarking on the next one. Early in one's contact with these substances, where there is a wealth of new experience, this may take several months. As one becomes more experienced, the integration time grows shorter, and the interval between trials may be shortened.

Many stop the use of psychedelics when they feel they have learned what they wished. But often it is likely that they halt because they have hit a deeply repressed, painful area that is heavily defended. The issue goes beyond purely personal material, however. One is unlikely to reach full realization without awareness, not merely of one's own pain and suffering, but of that of all mankind. This may help explain the Dark Night of the Soul, which is the final barrier to mystical union described by Evelyn Underhill in her classic book *Mysticism*. Since we are one, we must not only confront the personal Shadow, but the Shadow of all humanity. We can do this more readily when we discover the ample love that is available to dissolve all Shadow material.

Freeing constricted areas

There is another way in which psychedelics can serve the serious seeker. It often happens that those pursuing rigorous spiritual disciplines achieve elevated states by pushing aside or walling off certain aspects of behavior. With honest use, psychedelics will not permit such areas to remain hidden, but will insist upon their surfacing. One then experiences the great relief of being in touch with all aspects of one's being. The joy and thrill of being totally alive come from having complete access to all of one's feelings.

The trained user

There appears to be a cosmic law that says that giving our complete attention to an object, image, or idea with constancy, patience, and acceptance will allow its different attributes to unfold. Psychedelics greatly accelerate this process. To operate most effectively, the observer must have developed the ability to hold his mind steady so he can watch the process develop. Large doses can push one so hard that it is most difficult to do this. Therefore the best results are achieved by a "trained user"--a person who has learned to manage high doses of psychedelics, or who has learned to hold his mind steady enough to observe his inner process competently. As a user clears up his "inner stuff," he gains more freedom in directing his experience. At this stage, higher doses can be profitably used to penetrate deeper into the nature of Reality.

Interestingly, this concept of the trained user does not appear in the literature. But it is precisely the trained user who can best take advantage of the unfathomed range of wisdom and understanding contained in the far reaches of the mind. There seems to be no limit to the dimensions of understanding that can be experienced by the explorer who has the courage, integrity, and skill to navigate them. With integrity, and with the support of appropriate disciplines and friends, one can bring back a great deal for the betterment of oneself and mankind.

Are psychedelics necessary? Can't these same explorations be conducted by those who have mastered the skills of meditation? No doubt they can--with an enormous investment of time and effort. But it is unlikely that many Westerners will be willing to make such a commitment. For Western seekers, whose spiritual practice must usually be integrated with making a living, the proper use of psychedelics can considerably accelerate the process. However, it is not a path for everyone. Choice should be based on full knowledge of the factors involved.

Psychedelics are not a shortcut, as it is of little value to sidetrack important experiences. If enlightenment requires resolution of unconscious material (and my personal experience indicates that it does), those who aspire to such achievement must carefully consider the pace and intensity with which they are willing to encounter this vast range of dynamics. The psychedelic path, while much more intense than many other disciplines, is in a sense easier because it often provides an earlier and more profound contact with the numinous. Such contact inspires commitment and opens the door to more grace in surmounting uncomfortable material.

If our commitment is truly to the well-being and happiness of all sentient beings, then it is reasonable to study all useful tools for accomplishing these ends. Psychedelics, used with good motivation, skill, and integrity, can contribute much toward easing the pain and suffering of the world while giving access to wisdom and compassion for spiritual development.

The author has worked for many years in the field of psychedelic research. Between 1960 and 1970 he headed the International Foundation for Advanced Study, a research group conducting clinical studies with LSD and mescaline.

Entheogens are NOT Drugs

by

Keith Cleversley

original source: http://www.cleversley.com/on-being-human/entheogens-are-not-drugs/

Truth in Numbers

Before we can begin, a few critical details need to be heard as honestly and with as open a mind as possible, so we can engage in a fruitful dialog regarding an extremely difficult topic.

First, the fact that illicit drugs such as cocaine and heroin are directly responsible for thousands of deaths per year is never disputed. But what rarely gets discussed is the fact that some legalized drugs such as tobacco, alcohol, and prescription medication (which embody the very definition of drugs) are responsible for hundreds of thousands of deaths each and every year, year after year, and are actually more abused in far greater numbers than all illicit drugs combined. This means that millions of deaths have been the direct result of the use and abuse of illicit and legal drugs throughout history.

This is a staggering number.

Conversely, there are a number of ancient and sacred plants known as entheogens. The entire group of these plants is responsible for a negligible number to zero deaths per year. In fact; they may be responsible for under a dozen recorded deaths in their entire recorded history of use. Entheogens are also called "plant teachers" because of the effort required to work with these plants for responsible spiritual exploration; they are not the "quick fix" or the "escape" that abusers of illicit drugs and alcohol are hoping to find.

They are also more commonly (and recently) known as "psychedelics." This is exactly where the knee-jerk reactions often begin. But I ask to suspend your reaction, to reserve judgment until some important facts are understood as we first find some initial common ground. What we can agree on so far is this: The yearly death toll from entheogens/psychedelics is negligible to zero, in stark contrast to the countless millions of deaths throughout recorded history that illicit and legalized drugs are directly responsible for.

This is critical to hold in our minds as we continue.

The Food, Drug, and Cosmetic Act gives us some insight into what the government considers a drug. It's "a substance recognized in an official pharmacopoeia or formulary, a substance intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease, a substance other than food intended to affect the structure or function of the body, a substance intended for use as a component of medicine but not a device or component, part, or accessory of a device." For the sake of discussion, let's also see what Merriam Webster thinks a drug is: "something and often an illegal substance that causes addiction, habituation, or a marked change in consciousness."

When the group of substances, plants, and chemicals that fit even a part of the above definitions are grouped together and universally referred to as "drugs" this (perhaps intentionally) limits any possibility of engaging in an intelligent, unbiased, non-prejudiced discussion about the true difference between drugs that are dangerous, addictive, and often-abused, from those used ritualistically in cultures (entheogens) throughout the world and throughout our mutual human history. Despite the Roman Catholic assertion that indigenous cultures were primitive" and "heathens," it only takes a cursory glance at the state of our planet to get at least an inkling that the people who didn't overpopulate it or pollute it, who typically lived in harmony with their environment and who were connected to it and an integral part of it, may have something profound, even world-changing to teach us.

And, statistics that are difficult for many to look at continue with both over-the-counter and prescription medications. The #1 abused drug in America isn't illegal or illicit drugs, even if we include Cannabis in that group; it's prescription medication. OxyContin, a powerfully addictive narcotic with effects similar to opiates such as heroin became a leading drug of abuse in less than 10 years after its introduction.

Let's take a look at a common drug; aspirin. Aspirin reactions and interactions claim 37,000 lives per year. This is one of countless other drug interactions that cause everything from allergic reactions to death, yet few of us barely blink an eye when it comes to "death by aspirin." In a similar example, 16,500-20,000 deaths per year have been attributed to the use of non-steroidal anti-inflammatory drugs (NSAIDs). I already mentioned that The Center for Disease Control (CDC) reports that a staggering 430,000 deaths per year are attributable to the abuse of tobacco.

Yet the media never covers these things because there's no way to sensationalize it or prey on our fears like they can when the word "psychedelic" is uttered. Well, that, and there's not multi-billion dollar pharmaceutical, tobacco, or alcohol companies as well as their accompanying governmental lobbyists, or the many millions spent on marketing those drugs, often to unsuspecting populations.

On the other hand, entheogens induce almost universal anger, disdain, reaction, and judgment in even the most open-minded, especially when the word "hallucinogenic" accompanies it. Who could blame any of us for this reaction considering the many years of propaganda and false information perpetuated by the media looking for a great story, by corporations looking for more profits, by organized religions feeling usurped, or by the Federal Government looking to maintain control? Coupled with a systematic suppression of the ritualistic use of plant medicines and entheogens by countless cultures, shamanic or otherwise throughout the world and throughout history; the mainstream population has little hope of knowing any differently. This is thankfully changing with pioneering work by groups like M.A.P.S. and the Hefter Institute, who have not only revived clinical research into entheogens, but who've now offered scientific evidence that psychedelics and hallucinogens can help treat a wide range of trauma and disorders, ranging from PTSD to victims of rape and other abuse.

Regardless, the critical point is this: Regardless of any moral, ethical, or religious reasons anyone might have for objecting to entheogens and ethnobotanicals, if we can at least all agree that illicit drugs as well as particular legal drugs are far more of a dire concern due to sheer numbers alone, especially in regard to youth, then we have that critical common ground that will enable us to seek out the true answers to one of the most serious issues facing us today.

Addressing the Myth

The media are guilty of one of the crimes I usually associate with organized religion; of preying on our fear and using that fear to manipulate us. One of the most effective tactics is to repeat something enough times, loudly enough, and in enough ways that it eventually gets accepted as a fact. One example is this universally-recognized fear-inducing statement in relation to entheogens:

"Psychedelics make you jump out of tall buildings."

But the stark, often difficult-to-swallow truth is actually this: The above statement is categorically false and has simply been repeated so many times that it's now accepted as a fact. It plays so perfectly into our natural "fear of the unknown," also making entheogens a perfect fit to be the scapegoat.

There's little to no evidence to support the belief that psychedelics make you engage in fatal activities such as jumping out of buildings, though, but no one seems to notice or to take the time to truly find out for themselves. Conversely, as mentioned earlier, there is far more evidence supporting the fact that many of the demonized entheogens are clinically-proving to be of great benefit in many areas of medicine, or at least are showing great promise in medicine! But label anything with the word "psychedelic" or "hallucinogenic," and you're almost assured of getting whatever legislation you wish passed in relation to it regardless of the facts.

Salvia divinorum is one of the most controversial scapegoats in recent history. When news of a suicide hit the news, a diary entry was found that indicated the person who had committed suicide had taken Salvia divinorum at some point in the past and that, as a result of that experience, realized that there was no point to his life and that his only option was to kill himself.

A tragedy; no question.

But, instead of looking to the broader picture of this person's world, perhaps to the failure of the parents, or to the youth himself who was already so discontent with his world that he had considered suicide previous to ingesting Salvia divinorum"¦it's far more comfortable and easier to blame the hallucinogen as the reason for his death instead.

And we all so easily jump on the bandwagon. It only took the possibility; a mere MENTION of a hallucinogen to elicit sweeping changes to the laws in relation to it. In my eyes, this is not only a red herring, it's a matter of shooting the messenger as well, and as long as "justice is done" no one thinks to question.

Just in case there are those who feel I advocate entheogens to anyone and everyone, I feel the need to offer some clarity on that point: I don't think for a minute that everyone should ingest psychedelics. Many have a difficult enough time handling the waking reality we all find ourselves dealing with on a daily basis. The instantaneous dissolving of the ego can be quite a jarring experience, especially for those in such material-based societies, but the rewards can be equally as valuable. I don't feel that children, in an non-indigenous setting, should work with entheogens, just as I don't feel that kids should be using any drugs, whether it's alcohol, caffeine, tobacco, or even aspirin or Prozac.

The simple fact is this: Psychedelics have no reputable supporting evidence that they cause psychosis or lead one to commit suicide. Without belittling the importance of even a single death that may have been linked to any potentially aggravating factors, it's critically important to make this clear: The massive backlash from a single death in 3,000 years of safe use seems virtually inconceivable when considering the complete lack of outrage to the literally millions of deaths that have been caused by alcohol, tobacco, illicit drugs and prescription medication, often hundreds of thousands of deaths each and every year. How can this be?

It is incredibly odd that a single death, not even directly linked to the plant in question, has directly resulted in the outlawing of that plant, when millions of deaths directly linked to alcohol, tobacco, illicit drugs, and prescription medication have only resulted in stiffer laws or slaps on the wrist, rather than outright outlawing of this scourge. In fact, much legislation has repeatedly been passed to further ensure even more protection under the Federal Government for some of the most dangerous drugs plaguing our society today.

With Open Eyes

When viewed in this manner, it makes it obvious that preying on our fears of the unknown makes entheogens and psychedelics an easy target and scapegoat, effectively shifting the focus away from the true killers in our society.

As further evidence: There's mounting evidence that a legal drug such as Prozac has multiple instances of suicides and attempted suicides attached to it, yet no one is fighting to get Prozac outlawed. It's also been proven that places where Kava Kava is prescribed for depression instead of Prozac, there are fewer side effects and now, evidence that there are fewer depression-related deaths as well. This is key information that could help us all live longer, healthier and happier lives, yet this information, like the positive stories of the use of psychedelics and other psychoactive plants (like Kava Kava), are stifled because of the laws presently in place.

Kava Kava has also been used as an alternative to alcohol, and statistics show that in places where Kava is consumed more than alcohol, there are significantly lower incidents of violence and motor vehicle accidents. Surely this must count for something.

I typically leave the subject of Cannabis out of the discussion on purpose, but this is a prime example of an irrational war waged against a natural herb that has shown immense medical benefits. Although the Federal Government still won't change their policy on this ancient entheogen, a number of states have not only decriminalized cannabis, it has been publicly approved for medical use. Surely this is an indication that there are forces beyond our awareness at work that may not be providing us with the whole and complete truth, and are at least worth examining.

And this is but one entheogen of many that, for thousands of years, have been used successfully medicinally, but have since been blindly outlawed or treated as scapegoats. It will take a massive shift in consciousness, an evolutionary shift to effect a change. And that's actually at the core of what my entire mission on this planet presently revolves around: To be part of the voice for evolution in consciousness and attitude in relation to entheogens and the restoration to their proper place in the medicine cabinet of Mother Nature.

And the exciting news is that things ARE changing. Many states, instead of blindly outlawing Salvia divinorum as over 10 states have of this writing are drafting legislation so Salvia is legal to adults over 18 years of age. This is forward-thinking legislation that returns the right of adults to choose for the tools they want to work with to explore the contents of their own mind themselves. The truth about Cannabis is starting to vividly outshine the propaganda and unfounded outrage that has been mounted against it by the Federal government, and this gives me great hope for the future.

Even ecstasy, hallucinogenic mushrooms, and D.M.T., which are all Schedule I drugs in most of the world as of this writing, have clinical trials being conducted on each as we speak. The results have been astonishing. Ecstasy is proving to be extremely helpful for victims of violent crimes such as rape. Hallucinogenic mushrooms have been showing great promise for the treatment of severe depression. Marijuana has been proven to aid in several serious medical ailments. Ibogaine (another illegal hallucinogen) has proven to be extremely effective in treating addiction. And the list goes on.

CAN entheogens be dangerous? Of course they can. Should they be available to kids? Of course not. But blindly making them illegal, often at the expense of valid, deeply beneficial medical research is simply irrational. But until we can see beyond the lies, the propaganda, and the indoctrinated knee-jerk negative responses whenever the word "hallucinogen" is uttered, the battle will be slow, arduous, and often accompanied by feelings that the fight itself is futile.

Our ignorance and our mutual fallibility to believe what the government and media tells us is true is where their greatest power and our greatest weakness lies. It's easy to capitalize on. But I have two unconquerable allies in this fight: Truth and the Internet. Because of these two powerful forces, I believe it's only a matter of time before we are all forced to evolve our mass consciousness into something far more rational and mutually beneficial to all beings when it comes to the use of entheogens. I will always believe that truth will always win out in the end, no matter how demonized, oppressed, or ignored.

In closing, the word entheogen means "to reveal the Divine within." They are part of a cornucopia of plants that Mother Nature provides, enabling those who choose to do so to explore one's own consciousness, the nature of reality, and our mutual places in the universe. Perhaps this is one of the reasons why there is such a deeply indoctrinated and often irrational reaction to those things which may help expand our individual consciousness; they potentially threaten to undermine those in power. As as we all know, those in power are typically willing to hang onto it at all costs.

What Psychedelics Offer

One of my favorite quotes on psychedelics comes from both Terence McKenna and Dennis McKenna. Both feel that

For that reason alone, I will not give up the fight, and will continue to only get louder as time progresses.

If you want a more detailed discussion on the mechanism of psychedelics, read my "**Entheogens: More Than Chemical Reactions**" article.

Molecular Mysticism

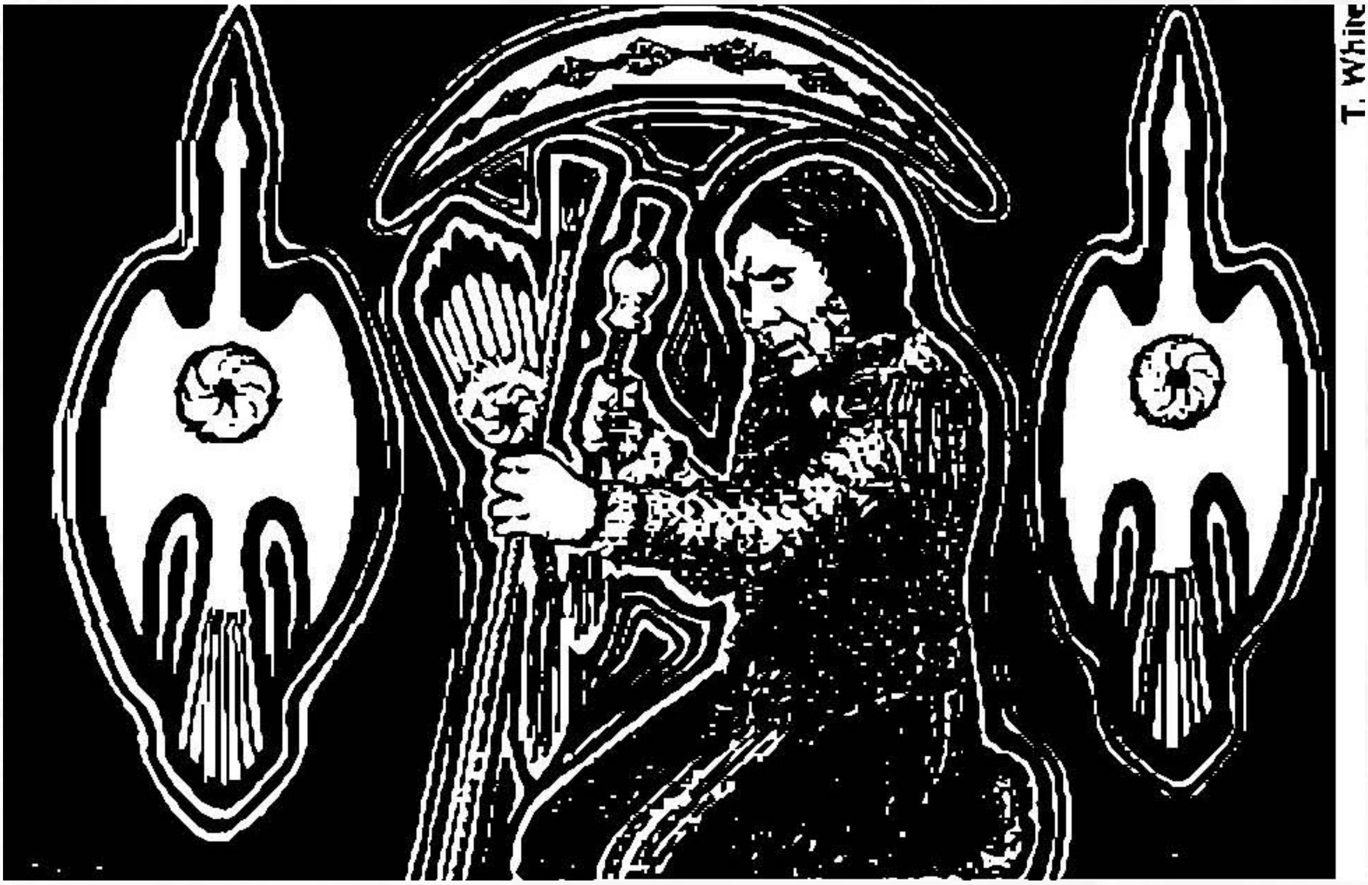
The Role of Psychoactive Substances in the Transformation of Consciousness

by

Ralph Metzner

An essay appearing in The Gateway to Inner Space, Christian Rätsch, editor. Published by Prism Press, Dorset, U.K., 1989.

original source: http://www.maps.org/research-archive/hmma/MetznerSpring88.pdf
backup source: http://www.psilosophy.info/resources/MetznerSpring88.pdf

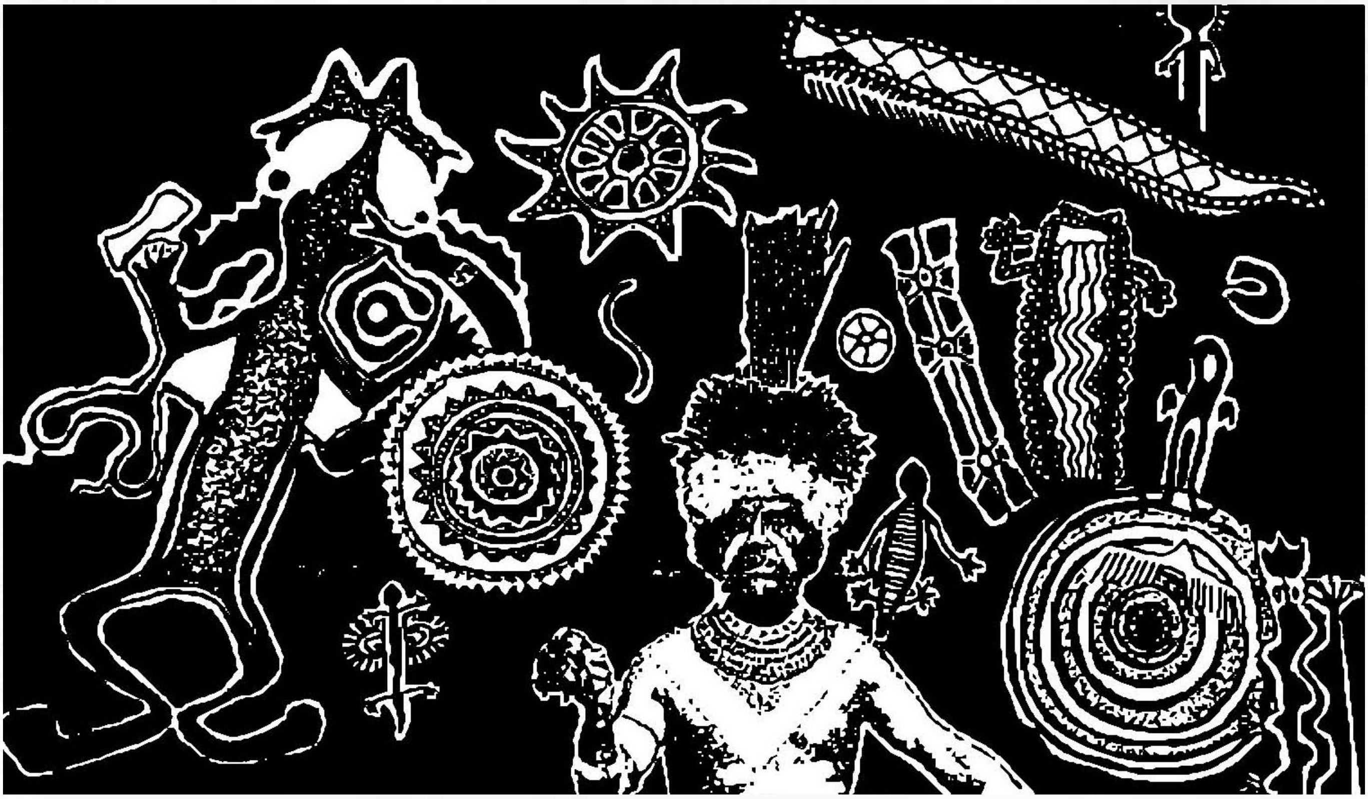


Peyote is a ceremonial sacrament of the Native American Church used for prayer and direct communion with the Spirit world.

There is a question that has troubled me, and no doubt others, since the heyday of psychedelic research in the 1960s, when many groups and individuals were concerned with the problems of assimilating new and powerful mind-altering substances into Western society. The question, simply stated, was this: why did the American Indians succeed in integrating the use of peyote into their culture, including its legal use as a sacrament to this day, when those interested in pursuing consciousness research with drugs in the dominant white culture succeeded only in having the entire field made taboo to research, and any use of the substances a criminal offense punishable by imprisonment? The use of peyote spread from Mexico to the North American Indian tribes in the latter half of the nineteenth century, and has found acceptance as a sacrament in the ceremonies of the *Native American Church*. It is recognized as one kind of religious ritual that some of the tribes practice; as well as being acknowledged by sociologists for its role as an antidote for alcohol abuse.

This intriguing puzzle in ethnopsychology and history was personally relevant to me, since I was one of the psychedelic researchers who saw the enormous transformative potentials of "consciousness expanding" drugs, as we called them, and were eager to continue the research into their psychological significance. It would be fair to state that none of the early explorers in this field, in the 1950s and early 1960s, had any inkling of the social turmoil that was to come, nor the vehemence of the legal-political reaction. Certainly Dr. Albert Hofmann, that epitome of the cautious, conservative scientist, has testified to his dismay and concern over the proliferation of patterns of abuse of what he so poignantly called his "problem child" *(Sorgenkind)*. Thus resulted the strange paradox that substances regarded as a social evil and a law-enforcement problem in the mainstream dominant culture are the sacrament of one particular sub-culture within that larger society. Since the Native American sub-culture is a much older and ecologically more sophisticated culture than the European white culture which attempted to absorb or eliminate it, and since many sensitive individuals have long argued that we should be learning from the Indians, not exterminating them, the examination of the question posed above could lead to some highly interesting conclusions.

The answer to the ethnopsychological puzzle became clear to me only after I started observing and participating in a number of other American Indian ceremonies, such as the healing circle, the sweat lodge, or the spirit dance, that did not involve the use of peyote. I noted what many ethnologists have reported: that these ceremonies were simultaneously religious, medicinal, and psychotherapeutic. The sweat lodge, like the peyote ritual, is regarded as a sacred ceremony, as a form of worship of the Creator; they are also both seen and practiced as a form of physical healing, and they are performed for solving personal and collective psychological problems. Thus, it was natural for those tribes that took up peyote to add this medium to the others they were already familiar with, as a ceremony that expressed and reinforced the integration of body, mind, and spirit. In the dominant white society, by contrast, medicine, psychology, and religious spirituality are separated by seemingly insurmountable paradigm differences. The medical, psychological, and religious professions and established groups, each separately, considered the phenomenon of psychedelic drugs and were frightened by the unpredictable transformations of perception and world-view that they seemed to trigger.

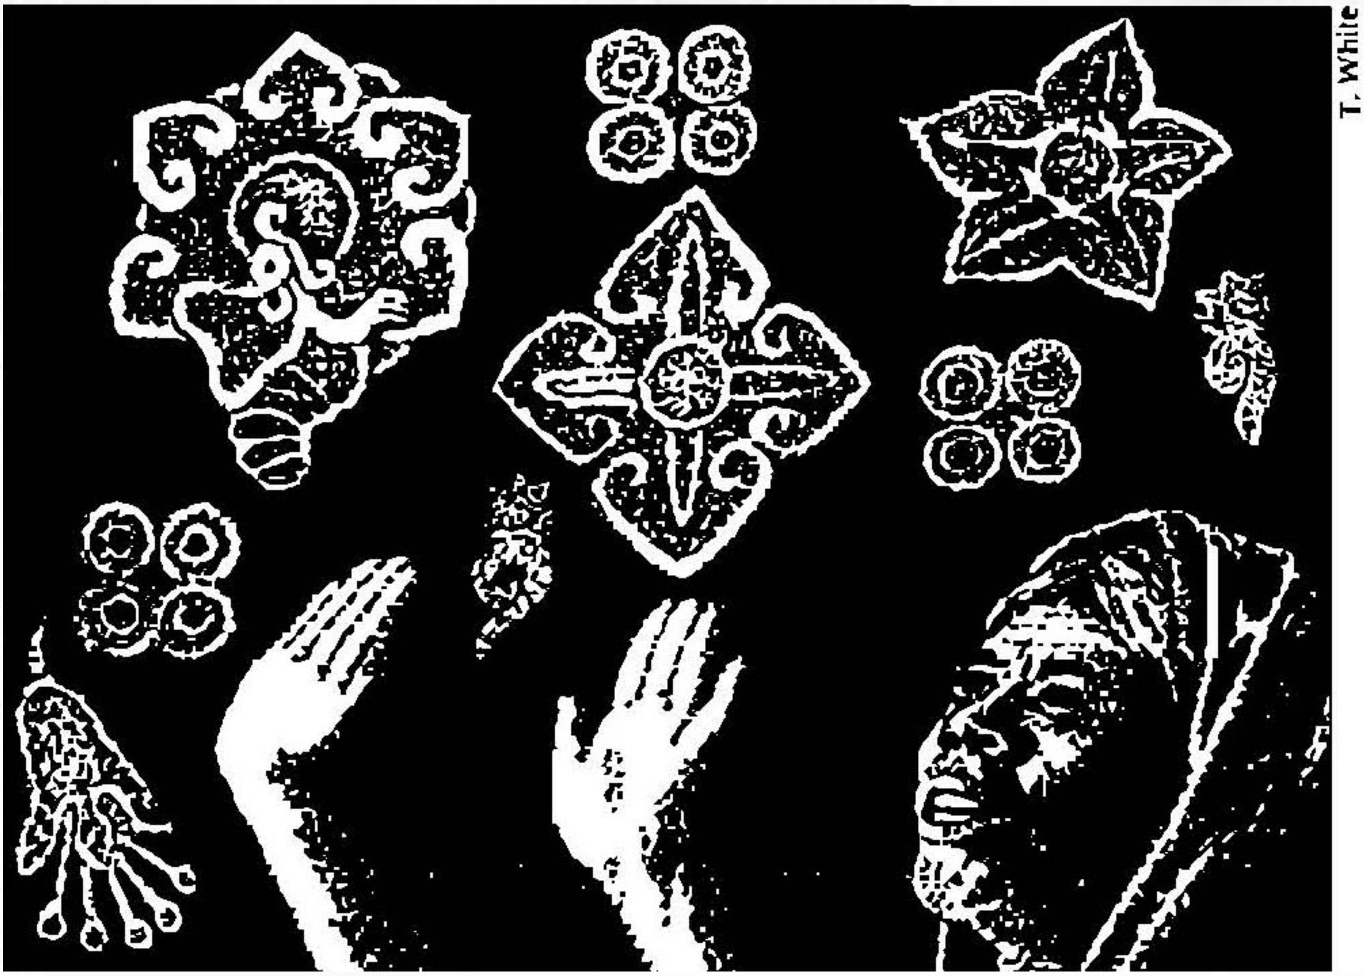


Datura has been used shamanically by several California tribes, and may have inspired some Chumash rock-art images.

Thus, the dominant society's reaction was fear, followed by prohibition, even of further research. None of the three established professions wanted these consciousness-expanding instruments; and neither did they want anyone else to have them of their own free choice The implicit assumption is that people are too ignorant and gullible to be able to make reasoned, informed choices as to how to treat their illnesses, solve their psychological problems, or practice their religion. Thus, the fragmented condition of our whole society is mirrored back to us through these reactions. For the Native Americans, on the other hand, healing, worship, and problem-solving are all subsumed in the one way, which is the way of the Great Spirit, the way of the Earthmother, the traditional way. The integrative understanding given in the peyote visions is not feared, but accepted and respected. Here, the implicit assumption is that everyone has the capability, indeed the task, to attune themselves to higher spiritual sources of knowledge and healing, and the purpose of ceremony, with or without medicinal substances, is regarded as a facilitating of such attunement.

Psychedelics as Sacrament or Recreation

Several observers, for example Andrew Weil (1985), have pointed out the historical pattern that as Western colonial society adopted psychoactive plant or food substances from native cultures (most of which are now regarded as belonging to the Third World), the pattern of use of such psychoactive materials devolved from sacramental to recreational. Tobacco was regarded as a sacred, or power plant, by Indians of North, Central, and South America (Robicsek 1978); it is still so regarded by Native Americans, even though in the white Western culture and in countries influenced by this dominant culture, cigarette smoking is obviously recreational, and has even become a major public health problem. The coca plant, as grown and used by the Andean Indian tribes, was treated as a divinity - Mama Coca - and valued for its health-maintaining properties; cocaine, on the other hand, is purely a recreational drug and its indiscriminate use as such also causes numerous health problems. In this and other instances desacralization of the plant-drug has been accompanied by criminalization. Coffee is another example: apparently first discovered and used by Islamic Sufis who valued its stimulant properties for long nights of prayer and meditation, it became a fashionable recreational drink in European society in the seventeenth century, and was even banned for a while as being too dangerous (cf. Emboden 1972; Weil & Rosen 1983). Even cannabis, the epitome of the recreational "high", is used by some sects of Hindu Tantrism as an amplifier of visualization and meditation.



The shamanic use of psychedelic mushrooms by Mesoamerican curranderos (healers) has been documented extensively by R. Gordon Wasson and others.

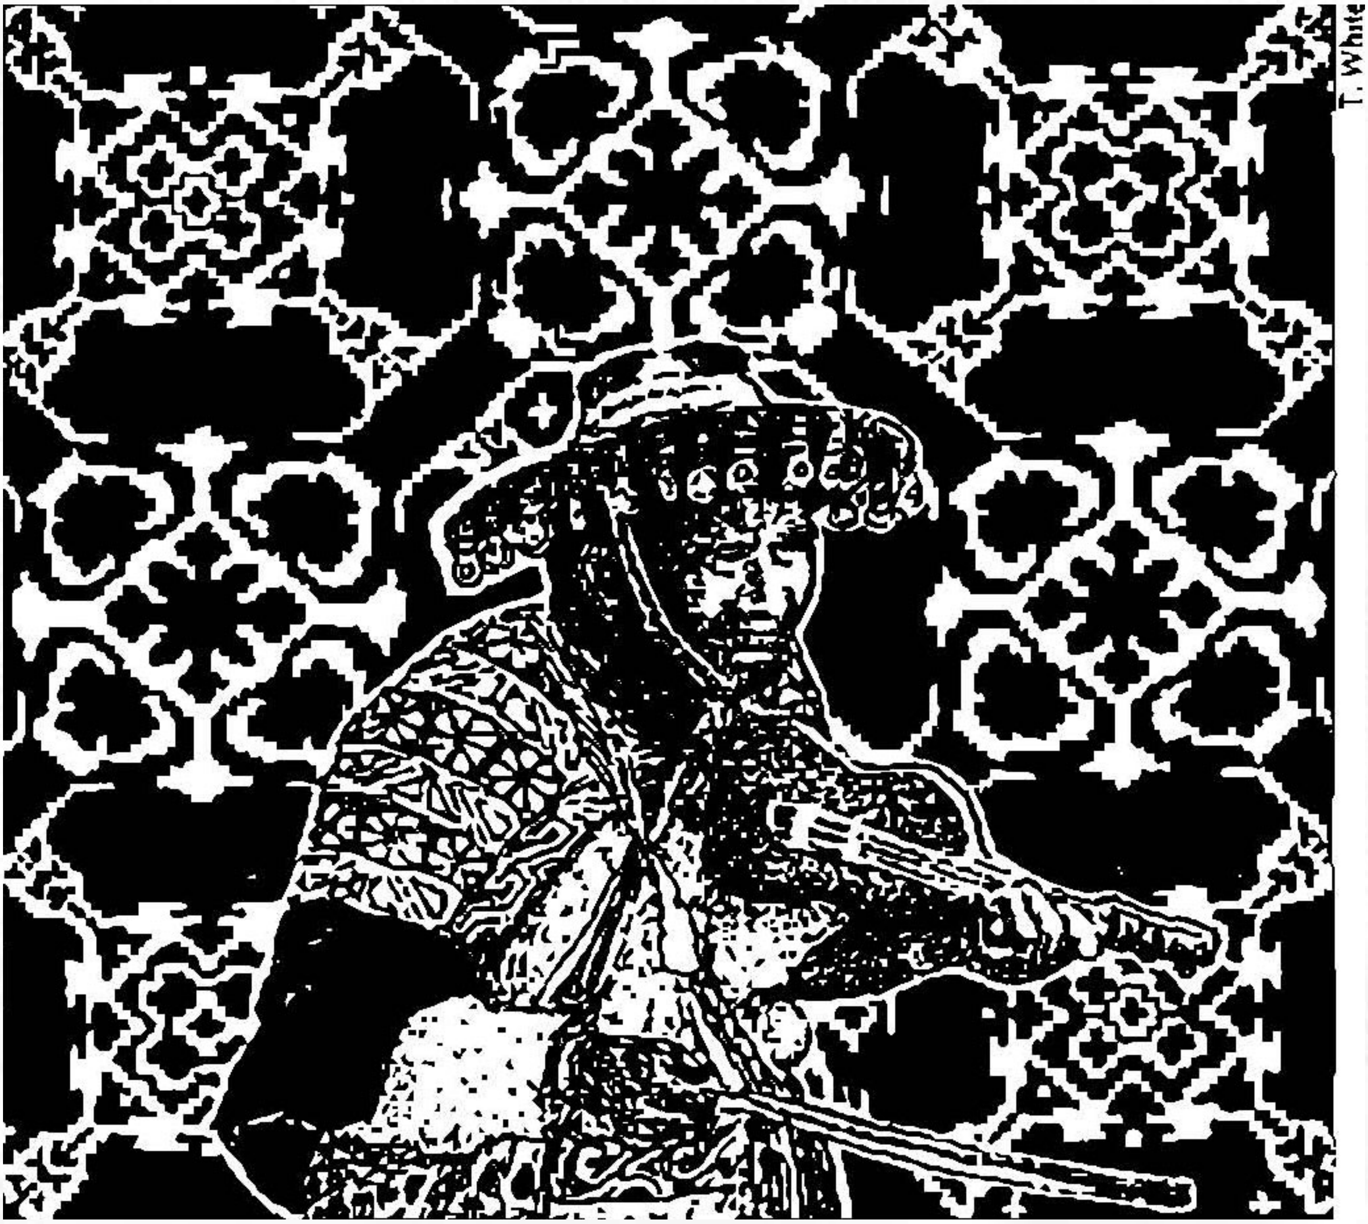
Since originally sacramental healing plants were so rapidly and completely desacralized upon being adopted by the West's increasingly materialistic culture, it should not be surprising that newly discovered synthetic psychoactive drugs have generally been very quickly categorized as either recreational, or "narcotic", or both. Concomitantly, as the indiscriminate, excessive, non-sacramental use of psychoactive plants and newly synthesized analogues spread, so did patterns of abuse and dependence; predictably, established society reacted with prohibitions, which in turn led to organized crime activities. This in spite of the fact that many of the original discoverers of the new synthetic psychedelics, people such as Albert Hofmann and Alexander Shulgin, are individuals of deep spiritual integrity. Neither they, nor the efforts of philosophers such as Aldous Huxley and psychologists such as Timothy Leary to advocate a sacred and respectful attitude towards these substances, were able to prevent the same profanation from taking place.

The newly discovered phenethylamine psychedelic MDMA provides an instructive example of this phenomenon. Two patterns of use seem to have become established during the seventies: some psychotherapists and spiritually inclined individuals began to explore its possible applications as a therapeutic adjuvant and as an amplifier of spiritual practice; another, much larger group of individuals began using it for recreational purposes, as a social "high" comparable in some respects to cocaine. The irresponsible and widespread use in this second category, by increasing numbers of people, understandably made the medical and law-enforcement authorities nervous, and the predictable reaction occurred: MDMA was classified as a Schedule I drug in the United States, which puts it in the same group as heroin, cannabis, and LSD, making it a criminal offense to make, use, or sell, and sending a clearly understood off-limits signal to pharmaceutical and medical researchers.

When Hofmann returned to the Mazatec shamaness Maria Sabina with synthetic psilocybin in order to obtain her assessment of how close the synthesized ingredient was to the natural product, he was following the appropriate path of acknowledging the primacy of the botanical over the synthetic. The argument could be made, and has been made, that perhaps for every one of the important synthetic psychedelics, there is some natural plant that has the same ingredients and that this plant is our connection to the larger lost knowledge of indigenous cultures. Perhaps it should be our research strategy - to find the botanical host for the psychedelics emerging from the laboratory. In the case of LSD, research on the use of morning glory seeds in ancient Mexico and baby woodrose in Hawaii, each of which contain LSD analogues, would allow us to discover a shamanic complex involving this molecule. If Wasson, Hofmann, and Ruck are correct in their proposal that an LSD-like ergot-derived beverage was used as the initiatory sacrament in Eleusis, the implications are profound (Wasson et al 1978). Using Rupert Sheldrake's theory of morphogenetic fields, one could suppose that by re-growing or re-hybridizing this particular plant, we could tune in to and re-activate the morphogenetic field of the Eleusinian mysteries, the ancient world's most awe-inspiring mystical ritual.

There is no inherent reason why sacramental use and recreational use of a substance, in moderation, could not co-exist. In fact, among Native Americans, tobacco often does play this dual role: after a sacred pipe ritual with tobacco or other herbs, participants may smoke cigarettes to relax. We know the sacramental use of wine in the Catholic communion rite; and we certainly know the recreational use of wine. We are able to keep the two contexts separate, and we are also able to recognize when recreational use becomes dependence and abuse. One could envision similar sophistication developing with regard to psychoactive plant products. There could be recognized sacramental and therapeutic applications; and certain patterns of use might develop that were more playful, exploratory, hedonistic and yet could be contained within a reasonable and acceptable social framework that minimizes harm.

The "abuse" of a drug, in such a relatively enlightened system, would not be a function of who uses it, or where it originated, or whether doctors or other authorities condone it, but rather of the behavioral consequences in the drug user. One becomes recognized as an alcoholic, i.e., an abuser of alcohol, when their interpersonal and social relationships are noticeably impaired. There should be no difficulty in establishing similar abuse criteria for other psychoactive drugs.



The ceremonial use of peyote is at the heart of the shamanic rituals, art and life of the Huichol Indians of the Mexican Sierra Madres.

Psychedelics as Gnostic Catalysts

In 1968, in a paper "On the Evolutionary Significance of Psychedelics" published in *Main Currents of Modern Thought*, I suggested that the findings of LSD research in the areas of psychology, religion, and the arts could be looked at in the context of the evolution of consciousness:

> If LSD expands consciousness and if, as is widely believed, further evolution will take the form of an increase in consciousness, then can we not regard LSD as a possible evolutionary instrument?... Here is a device which, by altering the chemical composition of the cerebro-sensory information processing medium, temporarily inactivates the screening-programs, the genetic and cultural filters, which dominate in a completely unnoticed way our usual perceptions of the world.

From the perspective of almost twenty years reflection, I now propose to extend and amplify this statement in two ways: (1) the evolution of consciousness is a transformation process that consists primarily in gaining insight and understanding, or *gnosis;* and (2) the acceleration of this process by molecular catalysts is not only a consequence of new technologies, but is also an integral component of traditional systems of transformation, including shamanism, alchemy, and yoga.

In psychedelic research, the "set-and-setting hypothesis", which was first formulated by Timothy Leary in the early 1960s, has become accepted by most workers in the field. The theory states that the content of a psychedelic experience is a function of the set (intention, attitude, personality, mood) and the setting (interpersonal, social, and environmental) and that the drug functions as a kind of trigger, or catalyst, or non-specific amplifier or sensitizer. The hypothesis can be applied to the understanding of any altered state of consciousness when we recognize that other kinds of stimuli can be triggers, for example, hypnotic induction, meditation technique, *mantra,* sound or music, breathing, sensory isolation, movement, sex, natural landscapes, a near-death experience, and the like. Generalizing the set-and-setting hypothesis in this way helps us to understand psychoactive drugs as one class of triggers within a whole range of possible catalysts of altered states (Tart 1972; Zinberg 1977).

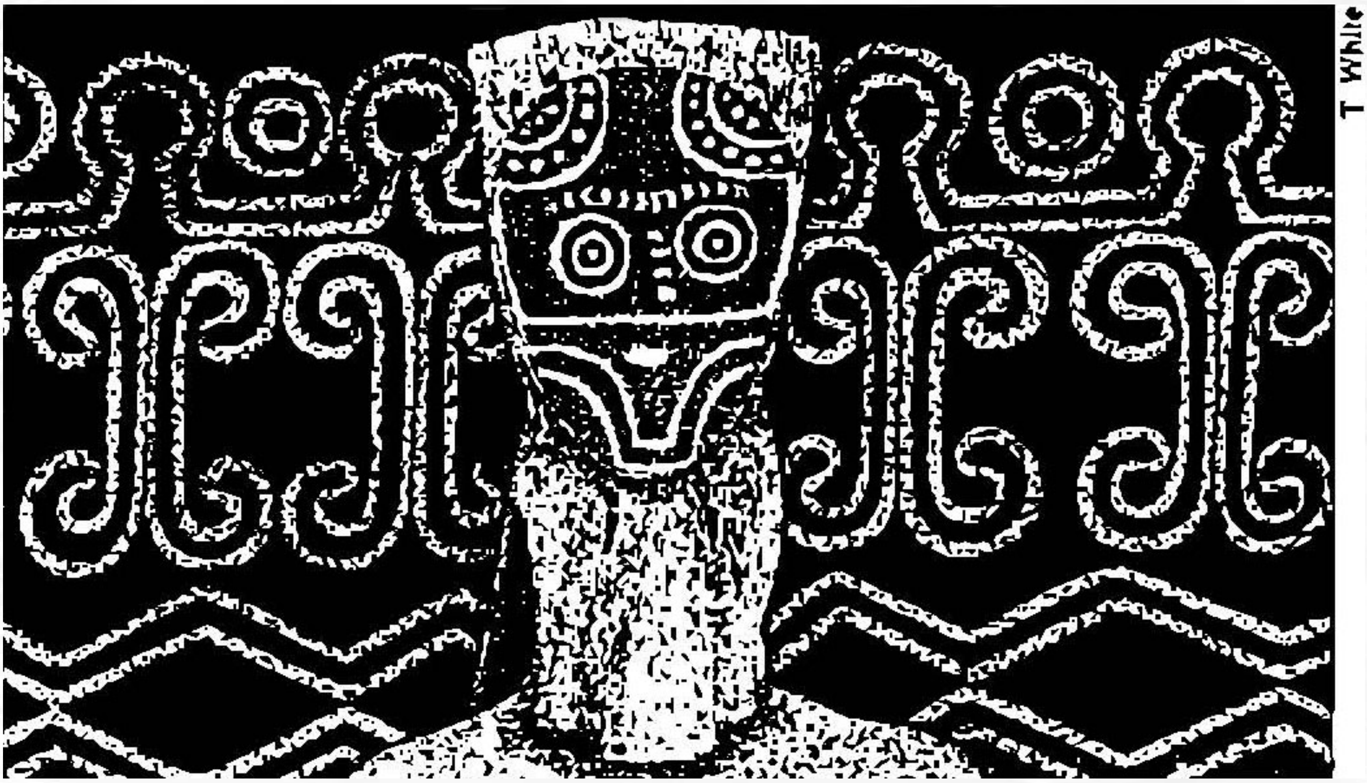
An important clarification results from keeping in mind the distinction between a state (of consciousness) and a psychological trait; between state changes and trait changes. For example, psychologists distinguish between state-anxiety and trait-anxiety. William James, in his *Varieties of Religious Experience* (1961), discussed this question in terms of whether a religious or conversion experience would necessarily lead to more "saintliness", more enlightened traits. This distinction is crucial to the assessment of the value or significance of drug-induced altered states. Only by attending to both the state-changes (visions, insights, feeling) and the long-term consequences, or behavioral or trait changes, can a comprehensive understanding of these phenomena be attained.

Timothy Leary, an earlly champion of LSD, emphasized that the content of a psychedelic experience is influenced by the setting (social, environmental, etc.) and the mind-set (intention, personality, mood, etc.) under which it is taken.

Having an insight is not the same as being able to apply that insight. There is no inherent connection between a mystical experience of oneness and the expression or manifestation of that oneness in the affairs of everyday life. This point is perhaps obvious, yet it is frequently overlooked by those who argue that, on principle, a drug could not induce a genuine mystical experience or play any role in spiritual life. The internal factors of "set", including preparation, expectation, and intention, are the determinants of whether a given experience is authentically religious; and equally, intention is crucial to the question of whether an altered state results in any lasting personality changes. Intention is like a kind of bridge from the ordinary or consensus reality state to the state of heightened consciousness; and it can also provide a bridge from that heightened state back to ordinary reality.

This model allows us to understand why the same drug(s) could be claimed by some to lead to nirvana or religious vision, and in others (for example, someone like Charles Manson) could lead to the most perverse and sadistic violence. The drug is only a tool, a catalyst, to attain certain altered states; which altered states being dependent on the intention. Rather, even where the drug-induced state is benign and expansive, whether or not it leads to long-lasting positive changes is also a matter of intention or mind-set.

The drug indeed seems to reveal or release something that is in the person; which is the factor implied in the term "psychedelic" - mind manifesting. In my opinion, the term "entheogen" is an unfortunate choice because it suggests the god within, the divine principle, is somehow "generated" in these states. My experiences have led me to the opposite conclusion: the god within is the generator, the source of life energy, the awakening and healing power. For someone whose conscious intention is a psychospiritual transformation, the psychedelic *can* be a catalyst that reveals and releases insight or knowledge from higher aspects of our being. This is, I believe, what is meant by *gnosis* - sacred knowledge or insight concerning the fundamental spiritual realities of the universe in general and one's individual destiny in particular.



The shamanic use of ayahuasca and other psychoactive plants by some Amazonian tribes has been documented extensively by anthropologists.

The potential of psychedelic drugs to act as catalysts to a transformation into *gnosis*, or direct, ongoing awareness of divine reality, even if only in a small number of people, would seem to be of the utmost significance. Traditionally, the number of individuals who have had mystical experiences has been very small; the number of those who have been able to make practical applications of such experiences has probably been even smaller. Thus, the discovery of psychedelics, in facilitating such experiences and processes, could be regarded as one very important factor in a general spiritual awakening of collective human consciousness. Other factors that could be mentioned in this connection are the revolutionary paradigm shifts in the physical and biological sciences, the burgeoning of interest in Eastern philosophies and spiritual disciplines, and the growing awareness of the multi-cultural oneness of the human family brought about by the global communications networks.

Psychedelics in Traditional Systems of Transformation

In my earlier writings, I emphasized the newness of psychedelic drugs, the unimaginable potentials to be realized by their constructive application; and I thought of them as first products of a new technology oriented towards the human spirit. While I still believe that these potentials exist, and that synthetic psychedelics have a role to play in consciousness research and perhaps consciousness evolution, my views have changed under the influence of the discoveries and writings of cultural anthropologists and ethnobotanists, who have pointed to the role of mind-altering and visionary botanicals in cultures across the world.

One cannot read the works of R. Gordon Wasson on the Mesoamerican mushroom cults (1980), or the work of Richard E. Schultes and Albert Hofmann (1979) on the profusion of hallucinogens in the Americas, or the cross-cultural work of such authors as Michael Harner (1973), Joan Halifax (1982), Peter Furst (1976), and Marlene Dobkin de Rios (1984), or the cross-culturally oriented medical and psychiatric researchers such as Andrew Weil (1980), Claudio Naranjo (1973), and Stanislav Grof (1985), or more personal accounts such as the writings of Carlos Castaneda, or Florinda Donner (1982), or the McKenna brothers (1975), or Bruce Lamb's biography of Manuel Cordova (1971), without getting a strong sense of the pervasiveness of the quest for visions, insights, and nonordinary states of consciousness; and, further, the sense that psychoactive plants are used in many, but by no means all, of the shamanic cultures that pursue such states. Thus, I have been led to a view closer to that of aboriginal cultures, a view of humanity in a relationship of co-consciousness, communication and cooperation with the animal kingdom, the plant kingdom, and the mineral world. In such a world-view, the ingestion of hallucinogenic plant preparations in order to obtain knowledge for healing, for prophecy, for communication with spirits, for anticipation of danger, or for understanding the universe, appears as one of the oldest and most highly treasured traditions.

The various shamanic cultures all over the world know a wide variety of means for entering non-ordinary realities. Michael Harner (1980) has pointed out that "auditory driving" with prolonged drumming is perhaps as equally widespread a technology for entering shamanic states as hallucinogens. In some cultures, the rhythmic hyperventilation produced through certain kinds of chanting may be another form of altered state trigger. Animal spirits become guides and allies in shamanic initiation. Plant spirits can become "helpers" also even when the plant is not taken internally by either doctor or patient. Tobacco smoke is used as a purifier, as well as a support to prayer. Crystals are used to focus energy for seeing and healing. There is attunement, through prayer and meditation, with deities and spirits of the land, the four directions, the elements, the Creator Spirit. Through many different means, there is the seeking of knowledge from other states, other worlds, knowledge that is used to improve the way we live in this world (through healing, problem-solving, etc.). The use of hallucinogenic plants, when it occurs, is part of an integrated complex of interrelationships between Nature, Spirit, and human consciousness.

Thus, it seems to me that the lessons we are to learn from these consciousness-expanding plants and drugs have to do not only with the recognition of other dimensions of the human psyche, but with a radically different world-view; a world-view that has been maintained in the beliefs, practices, and rituals of shamanic cultures, and almost totally forgotten or suppressed by twentieth century materialistic culture. There is of course a certain delightful irony in the fact that it has taken a material substance to awaken the sleeping consciousness of so many of our contemporaries to the reality of non-material energies, forms, and spirits.

In discussing alchemy as the second of the three traditional systems of consciousness transformation mentioned above, I would like to emphasize first that we have only the minutest shreds of evidence that ingestion of hallucinogens played any part in the European alchemical tradition. The use of solanaceous hallucinogens in European witchcraft, which is related to both shamanism and alchemy, has been documented by Harner (1973:125-130). Likewise, in Chinese Taoist alchemy, the use of botanical and mineral preparations to induce spirit-flight and other kinds of altered states has been discussed by Strickmann (1979). A complete account of the role of hallucinogens in alchemy has not as yet been written. Possibly our ignorance in this field is still a consequence of intentional secrecy on the part of the alchemical writers.

Mircea Eliade, in his book *The Forge and the Crucible* (1962), made a strong case for the historical derivation of alchemy from early Bronze Age and Iron Age metallurgy, mining, and smithing rites and practices. One could argue that alchemy is one form of shamanism: the shamanism of those who worked with minerals and metals, the makers of tools and weapons. Many of the concerns and interests of the alchemists parallel shamanic themes. There is the strong interest in purification and healing, in discovering or making a "tincture" or "elixir" that will give health and longevity. There are visions and encounters with animal spirits, some clearly from the imaginal realms. There are stories and visions of divine or semi-divine figures often personified as the deities of classical mythology. There is the recognition of the sacredness, the animating spirit, of all matter. And there is the integrated world-view, which sees spirituality, religion, health and illness, human beings, the natural world and its elements, all interrelated in a totality.

It might be objected that there does not seem to be the equivalent of a shamanic journey in alchemy; no clear indication of an altered state of consciousness in which visions, or power, or healing abilities are attained. It appears to me that the alchemical equivalent of the shamanic journey is the opus, the work, the experiment with its various operations, such as *solutio, sublimatio, martificatio*, and the like. The focus is more on the long-term personality and physical changes that the alchemical initiate has to undergo, just as the shaman in training does. The experiments in alchemy were regarded as meditative rituals, during which visions might be seen in the retort or furnace, and interior psychophysiological state changes triggered by the observation of chemical processes.

Furthermore, in an interesting recent work, R.J. Stewart (1985) has argued that in the Western tradition of magic and alchemy, which has roots in pre-Christian Celtic mythology and beliefs, and of which traces can still be found in folklore ballads, popular songs, and nursery rhymes, the central transformative experience was an underworld journey. This underworld or otherworld initiation involved taking a "journey" into other realms, encounters with animal and spirit beings, attunement with the land and the ancestors, meditative rituals centering around the tree of life symbolism, and other features that place this tradition clearly into the ancient stream of shamanic lore found in all parts of the globe.

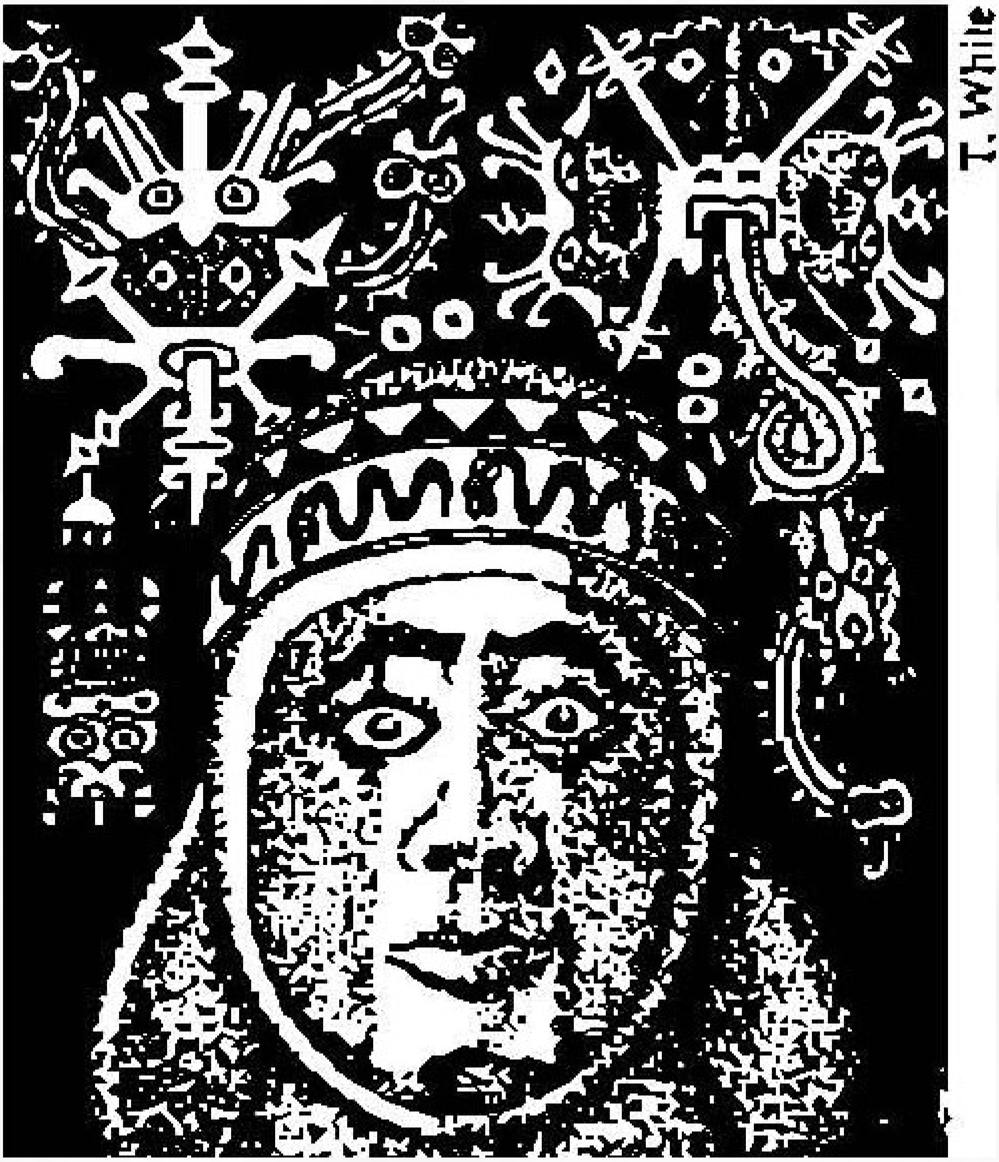
Turning now to yoga as the third of the traditional systems of evolutionary transformation of consciousness, we need not concern ourselves with the question of whether the use of visionary botanicals is a decadent or debased form of yoga, as Eliade (1958) seems to believe; or whether the use of hallucinogens was primary, in the Vedic-Indian tradition as the Soma cult, as Wasson (1968) has proposed. Sometimes, with the latter view, the corollary is proposed that yoga methods were developed when the drug was no longer available as an alternative means for attaining similar states. Suffice it to say that in the Indian yoga traditions, in particular the teachings of Tantra, we have a system of practices for bringing about a transformation of consciousness with many parallels to shamanic and alchemical ideas.

The use of hallucinogens as an adjunct to yoga practices is known to this day in India, among certain Shivaite sects in particular (Aldrich 1977). Those schools and sects that do not use drugs tend to regard those that do as decadent, as belonging to the so-called left-hand path of Tantra, which also incorporates ritual food and sexuality (*maithuna*) as valid aspects of the yogic path. Under the influence of nineteenth century Western occult and theosophical ideas, this left-hand path tended to be equated with "black magic", or "sorcery". In actuality, the designation left-hand path derives from the yogic principle that the left side of the body is the feminine, receptive side; and thus, the left-hand path is the path of those who worship the Goddess (*Shakti*), as the Tantrics do, and incorporate the body, the delight of the senses, nourishment, and sexuality into their yoga. Thus, as in shamanism and alchemy, we find here a strand of the tradition that involves respect and devotion to the feminine principle, the mother goddess, the earth and its fruit, the flesh and blood body, and the seeking of ecstatic visionary states.

It is true that the Indian yoga traditions seem not to have the same concern for the natural world of animals, crystals, and plants as is found in shamanism and alchemy. The emphasis is more on various inner and subtle states of consciousness. Nevertheless, there are interesting parallels between the three traditions. The focusing of inner light-fire energy in different centers and organs of the body, as practiced in Agni Yoga and Kundalini Yoga, is similar to the alchemical practice of purification by fire, and to shamanic notions of filling the body with light (Metzner 1971, 1986). The Indian alchemical tantric tradition had the concept of rasa, which is akin to the European alchemical concept of "tincture" or "elixir". *Rasa* has internal meanings-feeling, mood, "soul", and external referents-essence, juice, liquid. *Rasayano* was the path or way of rasa, the way of fluid energy-flow, that involves both external and internal essences[1]. As a third parallel, I will only mention the Tibetan Buddhist *Vajrayana* system, which is a remarkable fusion of Tantric Buddhist ideas with the Tibetans' original Bon shamanism: a system in which the various animal spirits and demons of the shamans and sorcerers have become transformed into personifications of Buddhist principles and guardians of the dharma (Govinda 1960).

Conclusions

It appears incontrovertible that hallucinogens played some role, of unknown extent, in the transformative traditions of shamanism, alchemy, and yoga. If we regard psychotherapy as the modern descendant of these traditional systems, then a similar, if limited, application of hallucinogens could be made in various aspects of psychotherapy. And this has in fact already occurred, as the various studies of psychedelics in alcoholism, terminal cancer, obsessional neurosis, depression, and other conditions testify (Grof 1985; Grinspoon & Bakalar 1979). It seems likely that these kinds of applications of psychedelics as adjuncts to psychotherapy will continue, if not with LSD and other Schedule I drugs, then with other, newer, perhaps safer psychedelics.



Archeological evidence suggests the use of psychedelics in ancient Peru.

What appears unlikely to me is that this kind of controlled psychiatric application will ever be enough to satisfy the inclinations and needs of those individuals who wish to explore psychedelics in their most ancient role, as tools for seeking visionary states and hidden forms of knowledge. The fact that the serious use of hallucinogens outside of the psychiatric framework continues despite severe social and legal sanctions suggests that this is a kind of individual freedom that will not be easy to abolish. It also suggests that there is a strong need, in certain people, to re-establish their connections with ancient traditions of knowledge in which visionary states of consciousness and exploration of other realities, with or without hallucinogens, were the central concern.

It may be that such a path will always be pursued by only a very limited number of individuals; much as the shamanic, alchemical, and yogic initiations and practices were pursued by only a few individuals in each society. I find it a hopeful sign that some, however few, are willing to explore how to reconnect with these lost sources of knowledge, because, like many others, I feel that our materialist-technological society, with its fragmented world-view, has largely lost its way, and can ill afford to ignore any potential aids to greater knowledge of the human mind. The ecologically balanced and humanistically integrated framework of understanding that the ancient traditions preserved surely has much to offer us.

Furthermore, it is very clear that the visions and insights of the individuals who pursue these paths are visions and insights for the present and the future, not just of historical or anthropological interest. This has always been the pattern: the individual seeks a vision to understand his or her place, or destiny, as a member of the community. The knowledge derived from altered states has been, can be, and needs to be applied to the solution of the staggering problems that confront our species. This is why the discoveries of Albert Hofmann have immense importance-for the understanding of our past, the awareness of our presence, and the safeguarding of our future. For, in the words of The Bible: "where there is no vision, the people perish."

Footnote

[1] We may say that the physico-chemical processes of the rasayana serve as the vehicle for psychic and spiritual operations. The elixir obtained by alchemy corresponds to the 'immortality' pursued by tantric yoga (Eliade 1958 283).

Psychedelic Yoga

by

Sri Brahmarishi Narad

The Application of Yoga Meditation Techniques to the Use of Psychedelic Sacraments

original source: http://deoxy.org/psychedelicyoga.htm

The fact that psychedelic drugs induce a greater sensitivity to subtle spiritual and psychic energies, and speed up the influx of impressions from deeper levels of consciousness, raises the immediate question of how these energies can be properly understood and handled. Obviously, if these energies are not guided, they can do more harm than good. The application of traditional Yoga meditation techniques while under psychedelic experiences, provides a constructive solution to this problem.

According to Yoga philosophy, the most spiritual and powerful aspect of man's nature is the faculty of attention or consciousness. The most fundamental aspect of man's free will is the choice as to what he allows his attention to dwell upon. The attention always has to be on something, but we can choose what we allow it to dwell upon. The goal of all Yoga practices is to discover and directly experience what the attention or faculty of consciousness in man is. The yogi seeks to know that principle by which all else is known. This goal is achieved by observing the observer or placing the attention on the attention itself. This may at first seem very abstract and hard to grasp in terms of practical application, but there are workable, time-proven methods for achieving this state of pure consciousness which when consistently applied and practiced are bound to yield results.

It should be constantly remembered during a psychedelic session that whatever perceptions, thoughts and even hallucinations occur, they are all the creations of one's own mind and consciousness, and are filtered through one's own instrument of perception. These perceptions are patternings of our own psychic energy. We give energy to whatever thoughts and feelings we allow the attention to dwell upon. Wherever the power of attention is focused, it generates mental and emotional energy in the form of its own lower overtones, thus feeding and energizing the thoughts and emotions which the attention dwells upon. It becomes clear that the key to remaining in control of a psychedelic experience is in controlling the flow of attention. Distractive experiences can be avoided in the first place, and the flow of attention can be properly directed by the use of Raja Yoga techniques of meditation. The following is a description of several such techniques which can all be applied while under the influence of LSD, marijuana, mescaline, DMT, hashish, psilocybin or other consciousness-expanding drugs. At this point, let us consider a basic rule to apply in case of paranoia or other unpleasant or frightening experiences while under the influence of a psychedelic drug. Realize that whatever you may be thinking, feeling or experiencing is being experienced by the consciousness within you. Then place your undivided attention on that consciousness which is experiencing whatever is happening to you. This process returns your consciousness to its own pure nature and disengages mental and astral thought forms. These destructive thought forms then dissipate and are dissolved back into the homogeneous, vibrational energy of the plane of energy substance from which they were originally molded. The strong light released by consciousness observing itself, helps to quickly dissolve and dissipate destructive thought forms. This happens because the strong lower overtones of pure consciousness which are generated, cancel out the discordant, out of phase vibrations of destructive thought forms.

If the attention wanders while practicing any of these meditation techniques, immediately bring the attention back to the process of meditation, and do this as many times as is necessary until the attention remains centered on the particular form of meditation which you are practicing. Inexperienced meditators have a tendency to fight distractions, which in itself, becomes a distraction. The attention can only dwell on one thing at a time. Simply bring it back to the thing you are meditating on. Another way of stopping distractions is simply to temporarily suspend the breathing process by neither breathing in or out. Since breathing is intimately tied to every biological process in the body, the instinct to survive (developed over billions of years of evolution) will interrupt the flow of attention into distractions and bring it to center on the awareness of the cessation of breathing. It is then an easy matter to resume normal breathing and to center the attention on the particular form of meditation being practiced.

Sound Current Meditation

Focus your full, undivided attention in the center of your brain where the pineal gland is located. Listen with your attention for whatever sounds present themselves. After awhile, you will hear sounds of various tones and pitches. At first, you may only hear the low hiss of random molecular noise in the ears, but in time, definite tones will present themselves like sustained notes on an organ. This sound is perceived directly by the brain and the subtle bodies themselves, and not through the outer physical organs of the ears. It is the sound of the vibration of conscious energy as it flows through the physical body and as it vibrates and circulates within the subtle bodies. You should focus your entire undivided attention on the sound of highest pitch that you can hear, and let it draw you up into higher and higher states of consciousness; also let the sound reveal and intensify the spiritual light. The better your concentration is, the louder and more distinct the sound will become. Experience the vibration of this sound expanding until it includes your whole head, your whole body, and ever-expanding volumes of space surrounding you. By this means, you will tune into the music of the spheres, and your whole being will become a receiver and transmitter of the harmonious rhythm of the universe. When you open your eyes after such a meditation, you may find your surroundings filled with blazing light. In the beginning, the sound current may appear in one localized part of the head; most likely in one of the ears. You should not listen to the sound current in the left ear because this is psychically harmful. Listen to it in the right ear, and gradually try to move it to the center and top of the brain. From this vertex center, known as the Sahasraram Chakra (whose associated gland is the pineal body), allow the vibration of the sound current to fill the entire head and to then expand beyond the head into the surrounding space. This is one of the classical methods and can lead to the highest type of experience.

Meditation on the Light in the Head

To practice this form of meditation, close your eyes, and observe your inner field of vision by focusing the attention at the point in the center of the forehead, just slightly above the point between the eyebrows. This location is called the Third Eye Center or Agna Chakra. It is related to the faculty of clairvoyant vision. The physical manifestation or anchorage point for the Agna Chakra is the pituitary gland, which is located in a bony cradle in back of the root of the nose. When you close your eyes, look steadily into your inner field of vision until light, color and patterns begin to appear. (This is looking with your attention and not with the physical eyes which should remain relaxed.) When most people close their eyes, initially they see a black void, but by looking steadily into this void, various colors and patterns will begin to appear. When this happens, simply observe them with your full, undivided attention as if you were intently watching a movie. Then periodically focus all of your attention within the smallest point that you can see in the center of your field of vision, and pierce through that point. After you have done this, the light will again blaze forth from the point in a new burst of energy, and you will find yourself at a higher rate of vibration or plane of energy. With continued practice of this form of meditation, you will become immersed in a blazing sea of light; and you will become a center from which that spiritual power is radiated.

By concentrating the attention in the Sahasraram Chakra or Thousand-Petalled Lotus, located at the top of the head, an experienced meditator can release an even more powerful radiation of light and spiritual energy. (It may take more work to activate this chakra; the beginner can get more immediate results by looking through the Agna Chakra or Third Eye Center.) The Sahasraram Wheel is the highest chakra; called the "Doorway to the Infinite" and the Brahmarandra or Hole of Brahma, it is the most powerful and spiritual of all the centers that can be awakened in man (with the possible exception of the Heart Chakra which is considered by some yogis to be of equal importance). When the Sahasraram Chakra is fully activated in a perfected yogin or saint, the white fire of Cosmic Kundalini descends upon him and blends with his own rising kundalini force, and the white light of spirituality radiates for miles around.

Meditation on the Chakras

By focusing the attention on various locations within the body, where the chakras are located, it is possible to activate these chakras and facilitate an increased flow of energy between the higher planes of energy and the subtle body, thus releasing an increased amount of spiritual energy. There are seven major chakras in the body which link together the physical body and the subtle energy bodies. The chakras are revolving vortexes of energy which act as mechanisms for the absorption and radiation of spiritual energy. In the physical body, they relate to glands and major nerve centers. In the etheric body, they are like wheels with flower petals which are created by a sort of stroboscopic effect of the revolving energy. The etheric chakra flowers are connected by a sort of funnel-like stem to the gland or nerve plexus to which they belong. In the astral body, the chakras appear as whirlpools of energy, like the eddies in a stream of water or in a basin of water when the stopper is pulled out. In the mental body, they appear as converging lines of light.

The Muladora Chakra is at the base of the spine and is the seat of the Kundalini Fire Wheel when aroused, which in the advanced stages of yoga, rises up through the center of the spine and activates the highest chakra in the cerebral cortex called the Sahasraram Chakra. The next chakra is called the Sacral Center or the Swadisthana Chakra. It relates to the adrenal glands and is related to the absorption of pranic vitality, which is in the air. The air absorbs this energy from solar radiation. There seems to be some differences of opinion between various texts as to whether the Muladora Chakra or Swadisthana Chakra relates most directly to the sexual functions. After the Swadisthana Chakra, comes the Manipara or Solar Plexus Center which relates to the digestive functions and vitality of the astral desires and feeling emotions. Next in ascending order is the Anahala or Heart Chakra, which relates to the source of spiritual energy and the higher emotions of love, altruism and benevolence. The next chakra is the Vishudha or Throat Chakra, which is related to the thyroid gland and has to do with the power of speech and relates to mantra yoga and the capacity for artistic creativity. This center is activated by chanting and singing. Next we have the Agna Chakra, which is located on the forehead, just slightly above and between the eyebrows. It is related to the pituitary gland and the subcortical areas of the brain. The Agna Chakra has to do with the higher mind faculties of clairvoyance, scientific reasoning, willing and philosophical thought. Development of the chakra awakens the ability to see and regulate astral and mental forces on the superphysical level. Above the Agna is the Sahasraram Chakra or Thousand-Petalled Lotus, which is related to the pineal gland and the cerebral cortex. It's located at the top of the head. It relates to the sound current and the faculty of clairvoyant hearing, and is the most spiritual of all the chakras. When this chakra is fully developed, union with God-consciousness is possible, and Illumination takes place.

By focusing the attention in any one of the chakras, the lower overtones of the concentration of consciousness in that location activates that chakra and increases the energy flow in it, making possible a conscious entry into the superphysical planes of energy. Meditation on the first three chakras, namely the Muladora Chakra, the Sacral Chakra and the Solar Plexus Chakra is not recommended because this can arouse lower emotions and sexual passions. This can allow entry to undesirable astral influences and cause psychological unbalance. It is better to work with the Heart Center, the Agna Chakra, and the Sahasraram Chakra because these are the most directly related to the unfoldment of superconsciousness; and when awakened, will automatically develop the lower chakras by changing the glandular balance of the body and by circulating new pranic forces through the energy channels or nodies of the etheric body as well as purifying and strengthening the astral and mental bodies. The hormones which the pituitary gland secretes, regulates the other glands in the body including the thymus gland, the thyroid gland, the adrenal gland and the sex glands as well as other glands. Once the pituitary gland is fully activated by the development of the Agna Chakra, all other glands are brought into proper chemical balance, thus helping to properly develop and raise the vibratory rate of all the lower chakras. In Kundalini Yoga, an advanced yoga practice, concentration is done on the Muladora Chakra at the base of the spine in order to arouse the Kundalini Fire and bring it through the center of the spine to activate the highest chakra, the Sahasraram, at the top of the head. If however, the Kundalini Fire is prematurely aroused and not properly directed, great damage can be done to the nervous system and to the etheric body. If the Kundalini force is not properly directed upwards, it can revert downward causing abnormal sexual desire and perversion. Therefore, arousing the Kundalini should only be done in advanced stages of yoga when a great deal of purification of the subtle bodies has taken place and soul control over the personality is well established.

The Combination of Mantra Yoga and Meditation

When doing Om chanting or other mantras, it is possible to activate various chakras. By chanting at varying pitches, you will make different tissues in the body vibrate, thus stimulating the nerve centers and the glandular centers, and activating the chakras associated with them. With a bit of experimentation, you will find which tones or pitches vibrate which parts of the body and which chakras. When this has been ascertained, then chant with full force while meditating in the chakra you wish to activate. The sound waves create vibration patterns in the etheric, astral and mental atmosphere, which you can develop the ability to see. They are multicolored and very intricate and beautiful, sometimes forming geometrical patterns and mandalas made out of threads of light. Music will have a similar effect. Just listen to the music during a psychedelic session while observing the inner light through the Agna Chakra or Third Eye Center. Then watch the color patterns change and develop with the music. Classical music and Indian ragas are especially good for this purpose.

Meditation on the I Am Principle

In the practice of this form of meditation, consciousness is made to dwell upon itself. When properly and successfully practiced, this is the most powerful and highest form of meditation. While focusing in the Heart Chakra or in the Sahasraram Chakra at the crown of the head, place the attention on the attention itself. If any distractions come in the form of thoughts and perceptions of a specific nature, then immediately concentrate your attention upon that consciousness in you which is the experiencer of those thoughts and perceptions. Even the manifestation of spiritual light and sound current should be regarded in this way. The sound current and the light are merely the lower overtone manifestations of the pure consciousness upon which you are meditating. The more you hold your attention steady in concentration upon itself, the more the light, sound current, electrical sensations in the body, feelings of magnetic force, sensations of weightlessness, etc. will manifest automatically. If, however, you allow your attention to become distracted by any of these manifestations, then you will be subject to the limitations of the thing by which you have been distracted; and the focusing of pure consciousness will be interrupted so that all of the things which are the lower overtones and by-products of the focusing of pure consciousness, possibly including the psychic manifestation which distracted your attention, will also stop. Seek ye first the kingdom of pure consciousness and all of these other psychic manifestations will be added unto you. Placing the attention on the attention itself can be done in any location in space since pure consciousness, which is the same as God, is an omnipresent principle. In the beginning, it will be found easiest to do this in one of the chakras, preferably the Heart Chakra or the Sahasraram or Head Center. The Agna Chakra or Third Eye Center located on the brow, can also be used with good results, but it is better to use the Sahasraram Chakra if you can activate it. With practice of this form of meditation, your pure consciousness will experience itself as a blazing sea of white light extending infinitely in every direction. The pure consciousness itself is crystalline and colorless, but it generates the white light which is the simultaneous presence of all of the colors which are the specific lower overtone rates of vibration, which the pure consciousness generates. The placing of the attention on the attention itself in a specific chakra, brings about a condition in that chakra, in which its vibration structure is harmonically and geometrically aligned in all of its planes of manifestation or rates of vibration. This creates common node points in the inner plane structure of the chakra. Vibrations of different frequencies and different wavelengths all begin and end together at these common node points. This is made possible by the fact that the wavelengths of the various vibrations and their frequencies all bear exact mathematical rates to each other, like the notes in a musical scale. Any vibrations which are out of phase in terms of their spatial distribution or vibratory rates are automatically canceled out by interfering with other waves at the common node points. Where several wavelengths, both short and long, begin and end their cycles together, it is possible to slip through the dimensions and to experience the higher spiritual rates of vibration and approach the Atman, which moves with infinite speed. At these common node points, the exchange of energy from one octave or plane to another, also becomes possible, allowing a flow of energy from the higher dimensions into the lower dimensions. Thus, a transmutation of those vibration patterns which exist on the lower dimensions into the higher ones becomes possible. The soul is then able to control the personality structure, making it a fit instrument of spiritual expression in the affairs of men. This form of meditation develops one-pointed concentration.

Since the use of psychedelic drugs stimulates the flow of a great amount of energy from higher planes into the lower planes, any thought and emotion patterns created during a psychedelic session are strongly imprinted and have a great deal of energy incorporated into their vibration structure. These thought and emotional patterns then act as powerful unconscious conditioning factors in our daily lives. It is therefore of the utmost importance that constructive imprints are made during a psychedelic session. Remaining in control of the attention can ensure this. In this regard, I would like to give a few final points of advice. Try not to focus the attention from one thing to another too quickly. Stay with a thought or meditation process until it is complete. Don't panic if frightening visions or hallucinations occur. Fear will make you concentrate on them all the more and thus feed them with the power of your attention. Remain detached and place your attention on that consciousness within you which is experiencing the hallucinations. Remember at all times that God exists in you in the form of your own power of attention and that power when properly directed, will control all lesser forces.

It is believed by some researchers that psychedelic drugs stimulate the secretion process of the pineal and pituitary glands, which are known by yogis and occultists to be related to the Sahasraram and Agna chakras (which are also called the Thousand-Petalled Lotus and the Third Eye Center). This stimulation increases the flow of energy between the etheric body and the physical body. It may be that psychedelic drugs place the cells of the physical body under stress so that they must speed up their activity to overcome the stress. When the cells increase their activity, their vibratory rates increase, thus putting them harmonically in resonance with the higher rates of vibration on the subtle superphysical planes of energy. This process makes possible the expression of a higher level of consciousness through the glandular system, brain and nervous system. The increased physical cellular activity requires more work and activity in the etheric body to sustain the stepped-up activity of the physical body. The vibratory rate of the etheric body is thus accelerated, requiring an increased activity in the astral body to sustain and remain harmonically in tune with the etheric body. The increased vibratory rate of the astral body requires a stepped-up activity and increased vibratory rate in the mental body. This in turn more fully tunes the mental body in to the power, love and wisdom of the soul. Thus an alignment of the whole being on all planes is facilitated, and a more rapid exchange of pattern imprints and energy between the various octaves or planes of energy takes place. It may also be that psychedelic drugs have a chemical structure such that they are perfectly in resonance with the lower overtones of certain key frequencies in the higher planes and can therefore act as a point of entry for the reflection of these vibrations in the physical body. They would therefore help to create common node points in the vibration structure of several different dimensions. Not only is the love, wisdom and power of the soul brought to bare in the life of the personality, but the fine organization of the physical body, the etheric, astral and mental bodies, which have been produced by the evolutionary process, are harmonically reflected and preserved in the soul. While the physical body is the least permanent, the densest and composed of the substance of the lowest plane, it is in terms of evolution, the newest and most highly organized in terms of structure. Therefore, a complete replica of it made out of the energy substance of the subtle planes, is an evolutionary gain for the soul and subtle bodies. When the physical body is sufficiently vivified by the influx of energy from the higher dimensions, it begins to create higher overtone reflections of itself in the akasha or energy substance of the higher planes, and thus its pattern is preserved and made immortal. Therefore, when properly used, psychedelic drugs help to speed up the evolutionary process. When man has evolved to superman, he will, under the direction of the superconscious mind in accordance with God's will as it manifests in evolution, take an active part in the molding and directing of the evolution of the mineral, vegetable, and animal kingdoms. Even today, his vibrations intimately affect for good or bad, those kingdoms in nature.

Manna From Heaven

by

Steve Kubby

From *Psychedelic Illuminations* Volume 1, Issue VII
Illustration by Gustave Doré

There are a great many people who would never consider the use of visionary plants to be a spiritual experience. These people believe that spiritual experiences must come directly from God and that the use of visionary plants goes against the teachings of the Bible. Contrary to this notion, the Bible never explicitly prohibits the use of visionary plants or potions. What you will find however, is many curious references to a spiritual food sent down from heaven by God, called manna.

The Bible never tells us exactly what manna was and where it came from, but there are many Old Testament passages which describe its physical qualities and conditions associated with its appearance. The Bible's first reference to manna is in the Book of Exodus as the children of Israel are fleeing from Egypt and following Moses into the wilderness. After six weeks of wandering, they began complaining to Moses that they are tired and hungry. What happens next is truly extraordinary:

> *Then said the LORD unto Moses, Behold, I will rain bread from heaven for you; and the people shall go out and gather a certain rate every day, that I may prove them, whether they will walk in my law or no (16:4).*
>
> *And when the dew that lay was gone up, behold, upon the face of the wilderness there lay a small round thing, as small as the hoar frost on the ground (16:14). And when the children of Israel saw if, they said one to another It is manna: for they wist not what it was. And Moses said unto them, This is the bread which the Lord hath given you to eat.*

When I read this passage, I was struck by the fact that manna easily fits the description of psilocybe mushrooms. For one thing magic mushrooms are small and round, and since they sprout so rapidly they would seem to appear overnight, as if out of the sky. Also, anyone harvesting them would immediately notice that they turn blue where torn and had no roots, giving more reason to believe that the mushrooms were of celestial origin. Note that manna does not just fall from heaven, but instead it is described as coming with the frost and dew, during the wet seasons. These are the precise weather conditions for mushrooms to thrive. And finally, manna is described as a bread.

Although translations have obscured the intent of this passage, it seems to be a description of how to find and identify manna and distinguish it from other non-psychoactive (or possibly lethal) mushrooms. Look for the small round things which are like bread, come with the rain, and seem to have heavenly (bluish) coloring. Psilocybe mushrooms also sprout in tiny pin heads which branch out in all directions and bear a resemblance to hoar frost.

It is also interesting to note that Moses tells the children of Israel that manna comes directly from Heaven to test them on whether or not they will walk in God's law. Here is evidence that manna was endowed with unusual spiritual powers, like those of magic mushrooms. However, manna does not automatically confer spiritual power. Instead, it serves as a test. Magic mushrooms would provide visionary experiences that would certainly test all who ingested them. Moses also said that the manna is literally the "bread of the lord" which is remarkably similar to the literal Aztec name for psilocybe mushrooms, "flesh of the gods."

But how and why did the manna suddenly appear? Again referring to the Bible, it is clear that the children of Israel had journeyed to a land where there was dew in the morning. As a large, nomadic tribe, the Israelites brought a lot of cattle and sheep together in the area. That meant a great deal of manure. The change of climate from the arid lands of Egypt to the dewy climate of the wilderness created ideal conditions for the propagation and spread of psilocybe mushrooms in livestock dung.

> *In Exodus 12:19-20, we find more references to manna.*

Anyone familiar with wild mushrooms knows that they go bad very quickly and shrivel up under the heat of the sun, exactly like manna.

It seems curious that Moses recognized the manna instantly when the children of Israel showed it to him. He knew that the manna would spoil if it was not picked and eaten in the morning. But how did Moses know about manna? Perhaps Moses knew about manna because he had already encountered the mushroom at the time he saw the burning bush. Referring to an earlier period of his life, we find that Moses:

> *...kept a flock of Jethro, his father in-law the priest of Midiam: and he led the flock to the backside of the desert, and came to the mountain of God, even to Horeb (3:1). And the angel of the LORD appeared unto him in a flame of fire out of the midst of a bush: and he looked, and behold, the bush burned with fire, and the bush was not consumed (3:2).*

Had Moses eaten the sacred mushroom while camped at the mountain? Here again we can only speculate that manure from his flock and a change in climate had created the proper environment for the mushrooms to fruit. Perhaps Moses ingested the mushrooms purely by accident, or perhaps his father in law, who we know was also a priest, had introduced Moses to the mushroom. Archaeological evidence of psychedelic mushroom use in Biblical times is well documented by Terence McKenna, so it is reasonable to conclude that Moses could have had some experience with visionary mushrooms.[1]

Later, in Numbers 11:6-9, manna is again described in terms that are remarkably similar to magic mushrooms:

> *But now our soul is dried away: there is nothing at all, beside this manna, before our eyes. And the manna was as coriander seed, and the colour thereof as the colour of bdelliaum. And the people went about and gathered it, and ground it in mills, or beat it in a mortar and baked it in pans: and made cakes of it: and the taste of it was as the taste of fresh oil. And when the dew fell upon the camp in the night, the manna fell upon it.*

Here we find manna described as before our eyes, having a neutral taste like fresh oil, and once again, the Bible mentions that manna appearing in the morning when the dew fell. The Old Testament even tells us what manna looks like, the manna was as coriander seed, and the colour thereof. When psilocybe mushrooms are dried, their range of colors is virtually identical to dried coriander seed. In both cases, with mushrooms and coriander seeds, we see great similarities in the texture, color, tones, contrasts and general visual appearance. The Children of Israel must have given great thought about how to transmit the appearance of manna so as to aid future generations who might encounter it. However, mushrooms were a mystery to the Hebrews and they were unable to predict where manna could be found. Little did they realize that the manure from their cattle was providing a means for the mushroom to find its way into their mountain campsites.

Notice that the manna was ground in mills or beat it in a mortar. That is odd because earlier we are told that manna was quite delicate and, then the sun wax hot, it melted. However, if manna was the psilocybe mushroom, then it was probably dried and then ground in order to be used for baking. In fact, dried magic mushrooms are quite hard. Grinding or crushing the dried mushroom and then baking with the powder would insure that the delicate psychoactive molecules retained their highest potency.

In the next passage, the Bible describes manna as having light tan color and texture like a wafer, certainly an accurate description of the color and texture of a dried psilocybe mushroom. We also learn that the taste of manna is no longer that of fresh oil but rather that of honey. According to McKenna's research, honey has long been used in Mexico as a preserve medium for psilocybin containing mushrooms. Perhaps the children of Israel had begun to mix honey with the manna to preserve its potency. We find that Moses announced that manna must be kept for future generations:

> *And the house of Israel called the name there of manna: and it was like coriander seed, white; and the taste of it was like wafers made with honey (l6:31). And Moses said, This is the thing which the LORD commandeth. Fill an omer of it to be kept for your generations: that they may see the bread where with I have fed you in the wilderness, when I brought you forth from the land of Egypt (l6:32).*

Again we are told to fill an omer with manna. But how much is a omer? Isaac Asimov, in his book on the Bible, concludes that an omer is about four liters, while the King James version of the Bible estimates an omer to be six pints. Psilocybe mushrooms are 92% water and only 8% remains when they are dried. Also, fresh mushroom take up a lot of space, due to their shape. So four liters of fresh magic mushrooms would yield less than a tenth of a liter, or about 1/4 cup of dried, powdered manna This corresponds closely with the amount of magic mushrooms required for a moderately strong dose when used for baking. This is important because it clearly shows that not only does manna have similar qualities to magic mushrooms, it also shows that it was also used in the same quantity as mushrooms. So manna matches psilocybe mushroom on both a qualitative and quantitative analysis providing a compelling argument that psilocybe mushrooms are in actuality "manna from Heaven."

Of course there are those who will remain eternally skeptical, but keep in mind that the description of manna given in the old testament bears an exact resemblance to mushrooms. Even if psilocybe mushrooms are not manna the similarities have indicated mushrooms as a possible candidate, and they certainly fit the bill for a "spiritual food". Unfortunately, when the Children of Israel finally reach the arid land of Canaan, the mysterious manna no longer appeared.

> *And the manna ceased on the morrow after they had eaten of the old corn of the land: neither had the children of Israel manna any more (Joshua 5:12).*

The children of Israel must have been deeply disappointed when they ran out of their sacred manna. We can see that they went to great lengths to preserve their knowledge about identifying and using manna The Old Testament contains detailed information about the color, texture, appearance, and relationship to dew, and the Old Testament even explains how manna is to be ground and then used in baking cakes. If the Israelites thought that manna was a magical event caused by God would they have bothered to note all the details about the identification of manna? What about the manna that Moses said must be put away for future generations? Turning to Hebrews 9:3-4 we find:

> *And after the second veil, the tabernacle which is called the Holiest of all: Which had the golden censer and the Ark of the Covenant overlaid round about with gold, wherein was the golden pot*

that had manna.

Here we learn that manna was to be kept in the Holiest of all, the Ark of the Covenant. Clearly, the manna was something of great spiritual power since the Hebrews treated it with such reverence and even went to such great lengths to see that manna be given to future generations. We must also consider the covenant that the Jewish people held with God which was celebrated through the act of circumcision. Why was this covenant with God associated with the removal of foreskin from infant males. Why not a tattoo, scar, article of clothing or jewelry? Perhaps the answer is that the circumcised penis bears a remarkable resemblance to psilocybe mushroom just before the partial veil has broken away from the mushroom caps and they are at their greatest potency. If the Ark of the Covenant was specifically built to store manna it is logical was also tied to manna through the ritual act of circumcision, which gave each Jewish male his own mushroom-like penis.

The discovery that manna was (and is) psilocybe mushrooms is not simply an issue of theological or academic debate. So great was the power conferred by manna, that this small band of wandering slaves were able to defeat all enemies who crossed their path even when confronted by armies that were bigger and better equipped. Jews, Christians and Moslems can all trace their roots to the children of Israel who ate manna for forty years and saw themselves as God's chosen people. Again, we are reminded of McKenna's thesis that those who ate psilocybe mushrooms had a survival advantage due to better visual acuity, heightened senses, better hunting skills, and for the children of Israel, better warrior skills. Manna gave the Hebrews their own covenant with God one that is even recognized today by Christians who believe that the Jews have already earned a special place as the Chosen People. Bible scholar Grant Jeffrey explains:

"The covenant which God made with Abraham and the kingdom promises to David, Solomon and all the prophets will be finally realized in the Millennial Kingdom... the Lord promised a new covenant with Ismel in which He would give them a new heart, forgiveness of sin, and the infilling of the Spirit to the renewed nation. This promised kingdom will provide the fulfillment of all the hopes and dreams of the Chosen People forever."[3]

What is the new covenant? It is the rediscovery of manna. Across the gulf of thousands of years the Bible transmits and accurate and detailed description of manna waiting for the time when the message can be decoded and manna can again fulfill its role as a celestial messenger. Manna was the basis of the Jewish covenant with God. Indeed, it is this covenant and the use of manna which has set the Jews apart as the Chosen People. The Bible is not the message, it only points the way. Manna is the holy sacrament that provides the means for God to "prove them, whether they will walk in my law, or no."

If manna is indeed the psilocybin mushroom, then this means that the Koran, Bible, and Torah were all inspired by psychedelically induced visions. The very foundations upon which these religions rest were derived from the mushroom experience. Moses and the children of Israel used the mushrooms as true sacraments to communicate with a Higher Power, also known as Allah, God and Yahweh. The discovery that manna is real and is available to us today means that like children of Israel we too can use manna to experience the joy, wisdom and spiritual renewal of the Chosen People.

Footnotes

The experiences resulting from the use of psychedelic drugs are often described in religious terms. They are therefore of interest to those like myself who, in the tradition of William James, [1] are concerned with the psychology of religion. For more than thirty years I have been studying the causes, the consequences, and the conditions of those peculiar states of consciousness in which the individual discovers himself to be one continuous process with God, with the Universe, with the Ground of Being, or whatever name he may use by cultural conditioning or personal preference for the ultimate and eternal reality. We have no satisfactory and definitive name for experiences of this kind. The terms "religious experience," "mystical experience," and "cosmic consciousness" are all too vague and comprehensive to denote that specific mode of consciousness which, to those who have known it, is as real and overwhelming as falling in love. This article describes such states of consciousness induced by psychedelic drugs, although they are virtually indistinguishable from genuine mystical experience. The article then discusses objections to the use of psychedelic drugs that arise mainly from the opposition between mystical values and the traditional religious and secular values of Western society.

The Psychedelic Experience

The idea of mystical experiences resulting from drug use is not readily accepted in Western societies. Western culture has, historically, a particular fascination with the value and virtue of man as an individual, self-determining, responsible ego, controlling himself and his world by the power of conscious effort and will. Nothing, then, could be more repugnant to this cultural tradition than the notion of spiritual or psychological growth through the use of drugs. A "drugged" person is by definition dimmed in consciousness, fogged in judgment, and deprived of will. But not all psychotropic (consciousness-changing) chemicals are narcotic and soporific, as are alcohol, opiates, and barbiturates. The effects of what are now called psychedelic (mind-manifesting) chemicals differ from those of alcohol as laughter differs from rage, or delight from depression. There is really no analogy between being "high" on LSD and "drunk" on bourbon. True, no one in either state should drive a car, but neither should one drive while reading a book, playing a violin, or making love. Certain creative activities and states of mind demand a concentration and devotion that are simply incompatible with piloting a death - dealing engine along a highway.

I myself have experimented with five of the principal psychedelics: LSD-25, mescaline, psilocybin, dimethyl-tryptamine (DMT), and cannabis. I have done so, as William James tried nitrous oxide, to see if they could help me in identifying what might be called the "essential" or "active" ingredients of the mystical experience. For almost all the classical literature on mysticism is vague, not only in describing the experience, but also in showing rational connections between the experience itself and the various traditional methods recommended to induce it: fasting, concentration, breathing exercises, prayers, incantations, and dances. A traditional master of Zen or Yoga, when asked why such-and-such practices lead or predispose one to the mystical experience, always responds, "This is the way my teacher gave it to me. This is the way I found out. If you're seriously interested, try it for yourself." This answer hardly satisfies an impertinent, scientifically minded, and intellectually curious Westerner. It reminds him of archaic medical prescriptions compounding five salamanders, powdered gallows rope, three boiled bats, a scruple of phosphorus, three pinches of henbane, and a dollop of dragon dung dropped when the moon was in Pisces. Maybe it worked, but what was the essential ingredient?

It struck me, therefore, that if any of the psychedelic chemicals would in fact predispose my consciousness to the mystical experience, I could use them as instruments for studying and describing that experience as one uses a microscope for bacteriology, even though the microscope is an "artificial" and "unnatural" contrivance which might be said to "distort" the vision of the naked eye. However, when I was first invited to test the mystical qualities of LSD-25 by Dr. Keith Ditman of the Neuropsychiatric Clinic at UCLA Medical School, I was unwilling to believe that any mere chemical could induce a genuine mystical experience. At most, it might bring about a state of spiritual insight analogous to swimming with water wings. Indeed, my first experiment with LSD-25 was not mystical. It was an intensely interesting aesthetic and intellectual experience that challenged my powers of analysis and careful description to the utmost.

Some months later, in 1959, I tried LSD-25 again with Drs. Sterling Bunnell and Michael Agron, who were then associated with the Langley-Porter Clinic, in San Francisco. In the course of two experiments I was amazed and somewhat embarrassed to find myself going through states of consciousness that corresponded precisely with every description of major mystical experiences that I had ever read. [2] Furthermore, they exceeded both in depth and in a peculiar quality of unexpectedness the three "natural and spontaneous" experiences of this kind that had happened to me in previous years.

Through subsequent experimentation with LSD-25 and the other chemicals named above (with the exception of DMT, which I find amusing but relatively uninteresting), I found I could move with ease into the state of "cosmic consciousness," and in due course became less and less dependent on the chemicals themselves for "tuning in" to this particular wave length of experience. Of the five psychedelics tried, I found that LSD-25 and cannabis suited my purposes best. Of these two, the latter - cannabis - which I had to use abroad in countries where it is not outlawed, proved to be the better. It does not induce bizarre alterations of sensory perception, and medical studies indicate that it may not, save in great excess, have the dangerous side effects of LSD.

For the purposes of this study, in describing my experiences with psychedelic drugs I avoid the occasional and incidental bizarre alterations of sense perception that psychedelic chemicals may induce. I am concerned, rather, with the fundamental alterations of the normal, socially induced consciousness of one's own existence and relation to the external world. I am trying to delineate the basic principles of psychedelic awareness. But I must add that I can speak only for myself. The quality of these experiences depends considerably upon one's prior orientation and attitude to life, although the now voluminous descriptive literature of these experiences accords quite remarkably with my own.

Almost invariably, my experiments with psychedelics have had four dominant characteristics. I shall try to explain them - in the expectation that the reader will say, at least of the second and third, "Why, that's obvious! No one needs a drug to see that." Quite so, but every insight has degrees of intensity. There can be obvious-1 and obvious-2, and the latter comes on with shattering clarity, manifesting its implications in every sphere and dimension of our existence.

slowing down of time

The first characteristic is a slowing down of time, a *concentration in the present*. One's normally compulsive concern for the future decreases, and one becomes aware of the enormous importance and interest of what is happening at the moment. Other people, going about their business on the streets, seem to be slightly crazy, failing to realize that the whole point of life is to be fully aware of it as it happens. One therefore relaxes, almost luxuriously, into studying the colors in a glass of water, or in listening to the now highly articulate vibration of every note played on an oboe or sung by a voice.

From the pragmatic standpoint of our culture, such an attitude is very bad for business. It might lead to improvidence, lack of foresight, diminished sales of insurance policies, and abandoned savings accounts. Yet this is just the corrective that our culture needs. No one is more fatuously impractical than the "successful" executive who spends his whole life absorbed in frantic paper work with the objective of retiring in comfort at sixty-five, when it will all be too late. Only those who have cultivated the art of living completely in the present have any use for making plans for the future, for when the plans mature they will be able to enjoy the results. "Tomorrow never comes." I have never yet heard a preacher urging his congregation to practice that section of the Sermon on the Mount which begins, "Be not anxious for the morrow...." The truth is that people who live for the future are, as we say of the insane, "not quite all there" - or here: by over - eagerness they are perpetually missing the point. Foresight is bought at the price of anxiety, and when overused it destroys all its own advantages.

awareness of polarity

The second characteristic I will call *awareness of polarity*. This is the vivid realization that states, things, and events that we ordinarily call opposite are interdependent, like back and front, or the poles of a magnet. By polar awareness one sees that things which are explicitly different are implicitly one: self and other, subject and object, left and right, male and female - and then, a little more surprisingly, solid and space, figure and background, pulse and interval, saints and sinners, police and criminals, in-groups and out-groups. Each is definable only in terms of the other, and they go together transactionally, like buying and selling, for there is no sale without a purchase, and no purchase without a sale. As this awareness becomes increasingly intense, you feel that you yourself are polarized with the external universe in such a way that you imply each other. Your push is its pull, and its push is your pull - as when you move the steering wheel of a car. Are you pushing it or pulling it?

At first, this is a very odd sensation, not unlike hearing your own voice played back to you on an electronic system immediately after you have spoken. You become confused, and wait for *it* to go on! Similarly, you feel that you are something being done by the universe, yet that the universe is equally something being done by you - which is true, at least in the neurological sense that the peculiar structure of our brains translates the sun into light, and air vibrations into sound. Our normal sensation of relationship to the outside world is that sometimes I push it, and sometimes it pushes me. But if the two are actually one, where does action begin and responsibility rest? If the universe is doing me, how can I be sure that, two seconds hence, I will still remember the English language? If I am doing it, how can I be sure that, two seconds hence, my brain will know how to turn the sun into light? From such unfamiliar sensations as these, the psychedelic experience can generate confusion, paranoia, and terror - even though the individual is feeling his relationship to the world exactly as it would be described by a biologist, ecologist, or physicist, for he is feeling himself as the unified field of organism and environment.

awareness of relativity

The third characteristic, arising from the second, is *awareness of relativity*. I see that I am a link in an infinite hierarchy of processes and beings, ranging from molecules through bacteria and insects to human beings, and, maybe, to angels and gods - a hierarchy in which every level is in effect the same situation. For example, the poor man worries about money while the rich man worries about his health: the worry is the same, but the difference is in its substance or dimension. I realize that fruit flies must think of themselves as people, because, like ourselves, they find themselves in the middle of their own world - with immeasurably greater things above and smaller things below. To us, they all look alike and seem to have no personality - as do the Chinese when we have not lived among them. Yet fruit flies must see just as many subtle distinctions among themselves as we among ourselves.

From this it is but a short step to the realization that all forms of life and being are simply variations on a single theme: we are all in fact one being doing the same thing in as many different ways as possible. As the French proverb goes, *plus ca change, plus c'est la meme chose* (the more it varies, the more it is one). I see, further, that feeling threatened by the inevitability of death is really the same experience as feeling alive, and that as all beings are feeling this everywhere, they are all just as much "I" as myself. Yet the "I" feeling, to be felt at all, must always be a sensation relative to the "other" - to something beyond its control and experience. To be at all, it must begin and end. But the intellectual jump that mystical and psychedelic experiences make here is in enabling you to see that all these myriad I - centers are yourself - not, indeed, your personal and superficially conscious ego, but what Hindus call the *paramatman*, the Self of all selves. [3] As the retina enables us to see countless pulses of energy as a single light, so the mystical experience shows us innumerable individuals as a single Self.

awareness of eternal energy

The fourth characteristic is *awareness of eternal energy*, often in the form of intense white light, which seems to be both the current in your nerves and that mysterious e which equals mc2. This may sound like megalomania or delusion of grandeur - but one sees quite clearly that all existence is a single energy, and that this energy is one's own being. Of course there is death as well as life, because energy is a pulsation, and just as waves must have both crests and troughs, the experience of existing must go on and off. Basically, therefore, there is simply nothing to worry about, because you yourself are the eternal energy of the universe playing hide-and-seek (off-and-on) with itself. At root, you are the Godhead, for God is all that there is. Quoting Isaiah just a little out of context: "I am the Lord, and there is none else. I form the light and create the darkness: I make peace, and create evil. I, the Lord, do all these things." [4] This is the sense of the fundamental tenet of Hinduism, *Tat tvam asi*-"THAT (i.e., "that subtle Being of which this whole universe is composed") art thou." [5] A classical case of this experience, from the West, is in Tennyson's Memoirs:

> A kind of waking trance I have frequently had, quite up from boyhood, when I have been all alone. This has generally come upon me thro' repeating my own name two or three times to myself silently, till all at once, as it were out of the intensity of the consciousness of individuality, the individuality itself seemed to dissolve and fade away into boundless being, and this not a confused state, but the clearest of the clearest, the surest of the surest, the weirdest of the weirdest, utterly beyond words, where death was an almost laughable impossibility, the loss of personality (if so it were) seeming no extinction but the only true life. [6]

Obviously, these characteristics of the psychedelic experience, as I have known it, are aspects of a single state of consciousness - for I have been describing the same thing from different angles. The descriptions attempt to convey the reality of the experience, but in doing so they also suggest some of the inconsistencies between such experience and the current values of society.

Opposition to Psychedelic Drugs

Resistance to allowing use of psychedelic drugs originates in both religious and secular values. The difficulty in describing psychedelic experiences in traditional religious terms suggests one ground of opposition. The Westerner must borrow such words as *samadhi* or *moksha* from the Hindus, or *satori* or *kensho* from the Japanese, to describe the experience of oneness with the universe. We have no appropriate word because our own Jewish and Christian theologies will not accept the idea that man's inmost self can be identical with the Godhead, even though Christians may insist that this was true in the unique instance of Jesus Christ. Jews and Christians think of God in political and monarchical terms, as the supreme governor of the universe, the ultimate boss. Obviously, it is both socially unacceptable and logically preposterous for a particular individual to claim that he, in person, is the omnipotent and omniscient ruler of the world - to be accorded suitable recognition and honor.

Such an imperial and kingly concept of the ultimate reality, however, is neither necessary nor universal. The Hindus and the Chinese have no difficulty in conceiving of an identity of the self and the Godhead. For most Asians, other than Muslims, the Godhead moves and manifests the world in much the same way that a centipede manipulates a hundred legs - spontaneously, without deliberation or calculation. In other words, they conceive the universe by analogy with an organism as distinct from a mechanism. They do not see it as an artifact or construct under the conscious direction of some supreme technician, engineer, or architect.

If, however, in the context of Christian or Jewish tradition, an individual declares himself to be one with God, he must be dubbed blasphemous (subversive) or insane. Such a mystical experience is a clear threat to traditional religious concepts. The Judaeo-Christian tradition has a monarchical image of God, and monarchs, who rule by force, fear nothing more than insubordination. The Church has therefore always been highly suspicious of mystics, because they seem to be insubordinate and to claim equality or, worse, identity with God. For this reason, John Scotus Erigena and Meister Eckhart were condemned as heretics. This was also why the Quakers faced opposition for their doctrine of the Inward Light, and for their refusal to remove hats in church and in court. A few occasional mystics may be all right so long as they watch their language, like St. Teresa of Avila and St. John of the Cross, who maintained, shall we say, a metaphysical distance of respect between themselves and their heavenly King. Nothing, however, could be more alarming to the ecclesiastical hierarchy than a popular outbreak of mysticism, for this might well amount to setting up a democracy in the kingdom of heaven - and such alarm would be shared equally by Catholics, Jews, and fundamentalist Protestants.

The monarchical image of God, with its implicit distaste for religious insubordination, has a more pervasive impact than many Christians might admit. The thrones of kings have walls immediately behind them, and all who present themselves at court must prostrate themselves or kneel, because this is an awkward position from which to make a sudden attack. It has perhaps never occurred to Christians that when they design a church on the model of a royal court (basilica) and prescribe church ritual, they are implying that God, like a human monarch, is afraid. This is also implied by flattery in prayers:

> O Lord our heavenly Father, high and mighty, King of kings, Lord of lords, the only Ruler of princes, who dost from thy throne behold all the dwellers upon earth: most heartily we beseech thee with thy favor to behold. ... [7]

The Western man who claims consciousness of oneness with God or the universe thus clashes with his society's concept of religion. In most Asian cultures, however, such a man will be congratulated as having penetrated the true secret of life. He has arrived, by chance or by some such discipline as Yoga or Zen meditation, at a state of consciousness in which he experiences directly and vividly what our own scientists know to be true in theory. For the ecologist, the biologist, and the physicist know (but seldom feel) that every organism constitutes a single field of behavior, or process, with its environment. There is no way of separating what any given organism is doing from what its environment is doing, for which reason ecologists speak not of organisms in environments but of organism-environments. Thus the words "I" and "self" should properly mean what the whole universe is doing at this particular "here-and-now" called John Doe.

The kingly concept of God makes identity of self and God, or self and universe, inconceivable in Western religious terms. The difference between Eastern and Western concepts of man and his universe, however, extends beyond strictly religious concepts. The Western scientist may rationally perceive the idea of organism-environment, but he does not ordinarily feel this to be true. By cultural and social conditioning, he has been hypnotized into experiencing himself as an ego - as an isolated center of consciousness and will inside a bag of skin, confronting an external and alien world. We say, "I came into this world." But we did nothing of the kind. We came out of it in just the same way that fruit comes out of trees. Our galaxy, our cosmos, "peoples" in the same way that an apple tree "apples."

Such a vision of the universe clashes with the idea of a monarchical God, with the concept of the separate ego, and even with the secular, atheist/agnostic mentality, which derives its common sense from the mythology of nineteenth-century scientist. According to this view, the universe is a mindless mechanism and man a sort of accidental microorganism infesting a minute globular rock that revolves about an unimportant star on the outer fringe of one of the minor galaxies. This "put-down" theory of man is extremely common among such quasi scientists as sociologists, psychologists, and psychiatrists, most of whom are still thinking of the world in terms of Newtonian mechanics, and have never really caught up with the ideas of Einstein and Bohr, Oppenheimer and Schrodinger. Thus to the ordinary institutional-type psychiatrist, any patient who gives the least hint of mystical or religious experience is automatically diagnosed as deranged. From the standpoint of the mechanistic religion, he is a heretic and is given electroshock therapy as an up-to-date form of thumbscrew and rack. And, incidentally, it is just this kind of quasi scientist who, as consultant to government and law-enforcement agencies, dictates official policies on the use of psychedelic chemicals.

Inability to accept the mystic experience is more than an intellectual handicap. Lack of awareness of the basic unity of organism and environment is a serious and dangerous hallucination. For in a civilization equipped with immense technological power, the sense of alienation between man and nature leads to the use of technology in a hostile spirit-to the "conquest" of nature instead of intelligent co-operation with nature. The result is that we are eroding and destroying our environment, spreading Los Angelization instead of civilization. This is the major threat overhanging Western, technological culture, and no amount of reasoning or doom-preaching seems to help. We simply do not respond to the prophetic and moralizing techniques of conversion upon which Jews and Christians have always relied. But people have an obscure sense of what is good for them - call it "unconscious self-healing," "survival instinct," "positive growth potential," or what you will. Among the educated young there is therefore a startling and unprecedented interest in the transformation of human consciousness. All over the Western world publishers are selling millions of books dealing with Yoga, Vedanta, Zen Buddhism, and the chemical mysticism of psychedelic drugs, and I have come to believe that the whole "hip" subculture, however misguided in some of its manifestations, is the earnest and responsible effort of young people to correct the self-destroying course of industrial civilization.

The content of the mystical experience is thus inconsistent with both the religious and secular concepts of traditional Western thought. Moreover, mystical experiences often result in attitudes that threaten the authority not only of established churches, but also of secular society. Unafraid of death and deficient in worldly ambition, those who have undergone mystical experiences are impervious to threats and promises. Moreover, their sense of the relativity of good and evil arouses the suspicion that they lack both conscience and respect for law. Use of psychedelics in the United States by a literate bourgeoisie means that an important segment of the population is indifferent to society's traditional rewards and sanctions.

In theory, the existence within our secular society of a group that does not accept conventional values is consistent with our political vision. But one of the great problems of the United States, legally and politically, is that we have never quite had the courage of our convictions. The Republic is founded on the marvelously sane principle that a human community can exist and prosper only on a basis of mutual trust. Metaphysically, the American Revolution was a rejection of the dogma of Original Sin, which is the notion that because you cannot trust yourself or other people, there must be some Superior Authority to keep us all in order. The dogma was rejected because, if it is true that we cannot trust ourselves and others, it follows that we cannot trust the Superior Authority which we ourselves conceive and obey, and that the very idea of our own untrustworthiness is unreliable!

Citizens of the United States believe, or are supposed to believe, that a republic is the best form of government. Yet vast confusion arises from trying to be republican in politics and monarchist in religion. How can a republic be the best form of government if the universe, heaven, and hell are a monarchy? [8] Thus, despite the theory of government by consent, based upon mutual trust, the peoples of the United States retain, from the authoritarian backgrounds of their religions or national origins, an utterly naive faith in law as some sort of supernatural and paternalistic power. "There ought to be a law against it!" Our law-enforcement officers are therefore confused, hindered, and bewildered-not to mention corrupted-by being asked to enforce sumptuary laws, often of ecclesiastical origin, that vast numbers of people have no intention of obeying and that, in any case, are immensely difficult or simply impossible to enforce-for example, the barring of anything so undetectable as LSD-25 from international and interstate commerce.

danger

Finally, there are two specific objections to use of psychedelic drugs. First, use of these drugs may be dangerous. However, every worth-while exploration is dangerous - climbing mountains, testing aircraft, rocketing into outer space, skin diving, or collecting botanical specimens in jungles. But if you value knowledge and the actual delight of exploration more than mere duration of uneventful life, you are willing to take the risks. It is not really healthy for monks to practice fasting, and it was hardly hygienic for Jesus to get himself crucified, but these are risks taken in the course of spiritual adventures. Today the adventurous young are taking risks in exploring the psyche, testing their mettle at the task just as, in times past, they have tested it - more violently - in hunting, dueling, hot-rod racing, and playing football. What they need is not prohibitions and policemen, but the most intelligent encouragement and advice that can be found.

escape from reality

Second, drug use may be criticized as an escape from reality. However, this criticism assumes unjustly that the mystical experiences themselves are escapist or unreal. LSD, in particular, is by no means a soft and cushy escape from reality. It can very easily be an experience in which you have to test your soul against all the devils in hell. For me, it has been at times an experience in which I was at once completely lost in the corridors of the mind and yet relating that very lostness to the exact order of logic and language, simultaneously very mad and very sane. But beyond these occasional lost and insane episodes, there are the experiences of the world as a system of total harmony and glory, and the discipline of relating these to the order of logic and language must somehow explain how what William Blake called that "energy which is eternal delight" can consist with the misery and suffering of everyday life. [9]

The undoubted mystical and religious intent of most users of the psychedelics, even if some of these substances should be proved injurious to physical health, requires that their free and responsible use be exempt from legal restraint in any republic that maintains a constitutional separation of church and state. [10] To the extent that mystical experience conforms with the tradition of genuine religious involvement, and to the extent that psychedelics induce that experience, users are entitled to some constitutional protection. Also, to the extent that research in the psychology of religion can utilize such drugs, students of the human mind must be free to use them. Under present laws, I, as an experienced student of the psychology of religion, can no longer pursue research in the field. This is a barbarous restriction of spiritual and intellectual freedom, suggesting that the legal system of the United States is, after all, in tacit alliance with the monarchical theory of the universe, and will, therefore, prohibit and persecute religious ideas and practices based on an organic and unitary vision of the universe. [11]

Footnotes

1. See W. James, *The Varieties of Religious Experience* (1902).
2. An excellent anthology of such experiences is R. Johnson Watcher on the Hills (1959).
3. Thus Hinduism regards the universe not as an artifact, but as an immense drama in which the One Actor (the *paramatman* or *brakman*) plays all the parts, which are his (or "its") masks or personae. The sensation of being only this one particular self, John Doe, is due to the Actor's total absorption in playing this and every other part. For fuller exposition, see S. Radhakrishnan, *The Hindu View of Life* (1927); H. Zimmer, *Philosophies of India* (1951), pp. 355-463. A popular version is in A. Watts, *The Book - On the Taboo Against Knowing Who You Are* (1966).
4. *Isaiah* 45: 6, *Isaiah* 45: 7
5. *Chandogya Upanishad* 6.15.3.
6. Alfred Lord Tennyson, *A Memoir by His Son* (1898), 320.
7. A Prayer for the King's Majesty, Order for Morning Prayer, *Book of Common Prayer* (Church of England, 1904).
8. Thus, until quite recently, belief in a Supreme Being was a legal test of valid conscientious objection to military service. The implication was that the individual objector found himself bound to obey a higher echelon of command than the President and Congress. The analogy is military and monarchical, and therefore objectors who, as Buddhists or naturalists, held an organic theory of the universe often had difficulty in obtaining recognition.
9. This is discussed at length in A. Watts, *The Joyous Cosmology: Adventures in the Chemistry of Consciousness* (1962).
10. "Responsible" in the sense that such substances be taken by or administered to consenting adults only. The user of cannabis, in particular, is apt to have peculiar difficulties in establishing his "undoubted mystical and religious intent" in court. Having committed so loathsome and serious a felony, his chances of clemency are better if he assumes a repentant demeanor, which is quite inconsistent with the sincere belief that his use of cannabis was religious. On the other hand, if he insists unrepentantly that he looks upon such use as a religious sacrament, many judges will declare that they "dislike his attitude," finding it truculent and lacking in appreciation of the gravity of the crime, and the sentence will be that much harsher. The accused is therefore put in a "double-bind" situation, in which he is "damned if he does, and damned if he doesn't." Furthermore, religious integrity - as in conscientious objection - is generally

tested and established by membership in some church or religious organization with a substantial following. But the felonious status of cannabis is such that grave suspicion would be cast upon all individuals forming such an organization, and the test cannot therefore be fulfilled. It is generally forgotten that our guarantees of religious freedom were designed to protect precisely those who were not members of established denominations, but rather such (then) screwball and subversive individuals as Quakers, Shakers, Levellers, and Anabaptists. There is little question that those who use cannabis or other psychedelics with religious intent are now members of a persecuted religion which appears to the rest of society as a grave menace to "mental health," as distinct from the old-fashioned "immortal soul." But it's the same old story.

11. Amerindians belonging to the Native American Church who employ the psychedelic peyote cactus in their rituals, are firmly opposed to any government control of this plant, even if they should be guaranteed the right to its use. They feel that peyote is a natural gift of God to mankind, and especially to natives of the land where it grows, and that no government has a right to interfere with its use The same argument might be made on behalf of cannabis, or the mushroom *Psilocybe mexicana Heim*. All these things are natural plants, not processed or synthesized drugs, and by what authority can individuals be prevented from eating theme There is no law against eating or growing the mushroom *Amanita pantherina*, even though it is fatally poisonous and only experts can distinguish it from a common edible mushroom. This case can be made even from the standpoint of believers in the monarchical universe of Judaism and Christianity, for it is a basic principle of both religions, derived from Genesis, that all natural substances created by God are inherently good, and that evil can arise only in their misuse. Thus laws against mere possession, or even cultivation, of these plants are in basic conflict with biblical principles. Criminal conviction of those who employ these plants should be based on proven misuse. "And God said 'Behold, I have given you every herb bearing seed, which is upon the face of all the earth, and every tree, in the which is the fruit of a tree yielding seed - to you it shall be for meat.... And God saw every thing that he had made, and, behold, it was very good." - Genesis 1:29, 31.

Revisiting the Tibetan Book of the Dead and The Psychedelic Experience

by

Ralph Metzner

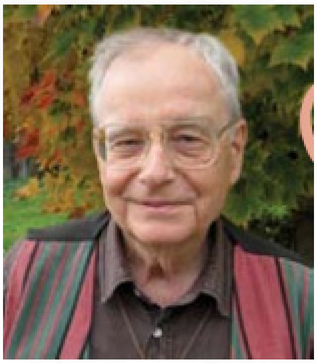
backup source: http://www.psilosophy.info/resources/v20n1-32to33.pdf



Undoubtedly the best-known text in world religious literature concerning itself with the afterlife and the process of reincarnation is the *Bardo Thödol*, popularly known as *The Tibetan Book of the Dead*. This book, in a translation by W.Y. Evans-Wentz, served as the text which Leary, Alpert and myself used as the basis for our guidebook on psychedelic states, *The Psychedelic Experience*, first published in 1964. In the years since its publication I have received many letters and comments to the effect that while most actual psychedelic experiences did not follow the idealized sequence of three stages laid out in the *Bardo Thödol*, what people appreciated about our manual were the recommendations to think of the psychedelic experience as an opportunity for psycho-spiritual practice and learning.

The original *Bardo Thödol*, is attributed to the legendary 8th century Indian Buddhist adept Padmasambhava, who brought Buddhism to Tibet. According to Buddhist scholar (and erstwhile participant in the Harvard psychedelic studies) Robert Thurman, who has published a more recent translation, the title of the work should more accurately read *The Great Book of Natural Liberation Through Understanding in the Between*. "Between" (as a noun) is Thurman's translation of the term bardo, - a somewhat odd linguistic choice for the concept which Evans-Wentz translated as "intermediate state." Actually, there are three bardo states described in the *Bardo Thödol* as being between life and death; and there are three additional bardo states, mentioned in appended *Root Verses*, that occur between birth and death - the waking life, dreaming and meditating.

Thus, it is clear that the term bardo refers to what in Western psychology is called a "state of consciousness." As I point out in my book *MindSpace and TimeStream*, a state of consciousness is always defined by a division of time between two transition points, - for example, "sleep" is the state between falling asleep and waking up. Whereas the Indian Vedanta identifies four common states - waking, sleeping, dreaming and meditating, Buddhist teachings mention three, combining the sleep and dream states. In the abovementioned *Root Verses* and other Tibetan Buddhist texts, there are descriptions of six yogas - practices for becoming lucid and liberated in each (or from each) of the six bardo states. In recent years, several Tibetan lama-teachers have expounded on the yoga of dreams - and such teachings converge with Western psychological research on the induction of lucid dreaming.

The *Bardo Thödol* concerns itself with providing guidance for the dying person on how to find their way through the three bardo states, giving detailed and explicit instructions how people can be helped to make the most favorable kind of rebirth possible. It teaches that liberation from the samsaric round of conditioned existence can occur in, or from, any of the bardo states, if we understand and remember the teachings, recognize the bardo state we are in, and choose the most enlightened conscious option available to us.

The teachings of the *Bardo Thödol*, in outline, are that immediately at death, in the bardo of the moment of dying, highly proficient meditators who can maintain one-pointed concentration will be able to attain liberation. Most people are not able to concentrate, however, get caught up in fear and confusion and enter into the second phase, called the bardo of the experiencing of reality, in which there are visions of "peaceful and wrathful deities." The deceased is reminded not to be overwhelmed by either the heavenly or the hellish visions, but to remember that they are all projections of one's own mind. Due to lack of training and/or preparation on the part of most ordinary people, the bardo traveller, after repeatedly lapsing into unconsciousness, then finds himself in the third phase, the bardo of seeking rebirth, in which he wanders about seeking to orient himself again to ordinary existence.

Although the *Bardo Thödol* does not explicitly mention the prenatal epoch as such, we can find in the teachings of the after-death bardo states some suggestive parallels with findings now emerging out of the work of prenatal regression therapists and past-life therapists. My own understandings of these areas have been deepened by my own participation in such explorations, using psychological, shamanic, yogic and alchemical methods, which I call divinations, for myself and with individuals and groups. At times, my explorations have involved the amplification of perception through psychedelic substances (where this was permissible).

The work of the prenatal regression therapists has uncovered cellular memories of conception, including the impact of the attitudes and expectations of father and mother at the time of conception. Past-life therapists now speak of a series of learning experiences undergone by the soul during the interlife period, that can be remembered in deep trance states. Prior to what is experienced as the descent into form at conception, there is a meeting with a group of meta-physical human spirits, called the soul council, at which the decision to incarnate is made, according to one's intentions, choosing the parents and circumstances of one's incarnation or rebirth.

According to the *Bardo Thödol*, in the phase of rebirth the traveler in the intermediate realms is repeatedly admonished to remember where he is, and that his thoughts and intentions will profoundly affect the kind of experience he/she may have. The deceased is reminded of the six possible worlds of samsara (existence) into which he might find him or herself drifting, carried along by the karmic propensities of their previous existence. They are advised to avoid the hell worlds, and the worlds of pretas and asuras, but, if rebirth is unavoidable, to go with the heavenly worlds of benign spirits (devas) or thehuman world - considered to be offering the best opportunities for liberation.

Then follow a series of instructions on how to "close the womb-door," the point here being to delay the rebirth as long as possible, so that one can prolong one's stay in the higher planes and avoid being sucked into unfavorable birth forms by one's karmic propensities. The first method of closing the womb-door is to remember that you are in this bardo of rebirth and to focus on positive intentions: "this is a time when earnestness and pure love are necessary." The second method of closing the womb-door is used as the deceased has visions of males and females coupling: he/she is to think of them as a divine Father-Mother pair, and withhold from joining them. The third, fourth and fifth methods of closing the wombdoor involve further ways of dealing with the visions of a man and woman copulating.

When we wrote *The Psychedelic Experience*, we interpreted these passages in the *Bardo Thödol* as referring to the sexual hallucinations that are not uncommon in psychedelic states. In the light of my subsequent experiences and of the literature on prenatal regression therapy, I now believe that the visions of couples copulating refer to memories of our own conception. In directed hypnotic and psychedelic trance states, people can remember, as souls, choosing the parents and existential conditions of their conception and birth to come and how that choice relates to their life-purpose. I myself have come to understand how my choice of parents of different nations (Germany and England), that were soon to be embroiled in world war, related to my life's work or mission. I know of artists or musicians, who remember choosing, as souls, to be conceived and born into a family where their artistic inclinations can be nurtured.

According to the *Bardo Thödol*, if after using the various methods of preventing or postponing rebirth by meditating with conscious intention on light, one is still drawn into a womb for birth, the deceased is given instructions for "choosing of the womb-door." The soul is advised to choose a human birth in an area in which religion prevails, and, "being born so, be endowed with great merit so as to be able to serve all sentient beings. Thinking thus, direct your wish, and enter into the womb." This is then, the moment of conception, where the soul descends from the higher realm where it has made its choice for a particular incarnation, in a particular family at a particular place and time.

To summarize, the instructions for the most favorable kind of re-birth, are: to delay the return from the light- and wisdom-filled heaven worlds as long as possible, and when the time comes, which you know by seeing the acts of conception between men and women, to choose a birth family where the likelihood of coming into contact with spiritual teachings are greatest. The ending of the interlife period is the beginning of the bardo of rebirth: the decision is made to reincarnate, in a blending of karmic tendencies and conscious choice, and conception takes place in a fleshly human womb. This rebirth phase then ends with the actual physical birth, nine months later, when we start cycling through the three bardos of waking life, dreaming and meditating.

The Teonanacatl - In Pre-conquest Accounts and Today

by

Types of Hallucinatory Mushrooms
Mushrooms in pre-Conquest Accounts
The Mushroom Party (translation of the text)
Mushrooms Today
Conclusion

Brother Toribio de Benavente, better known as Motolinia, describing the idolatry and bad ha bits of the Mexican Indians, gave this unusual report about one of their lesser known vices:

> They had another drunkenness which made them more cruel: which was of some small mushrooms, which are found here as in Castilla; however the ones here are of such nature that eaten raw and being sour, one drinks afterwards or eats them with a hit of honey; and after a little while they were seeing a thousand visions, especially of snakes, and as they went completely out of their minds, it seemed to them that their legs and body were full of worms which were eating them alive, and thus, half raving, they went out of the house, wishing that somebody would kill them, and with that bestial drunkenness and the trouble they felt, it would happen sometimes that they would hang themselves. And they were also against the others much more cruel. They called these mushrooms *teonanacatl*, which means flesh of the Cod (the demon they adored) and in that manner, with that bitter food, their cruel god held communion with them.[1]

Other pre-Conquest accounts, describing hallucinatory mushrooms and their effects, all written in the 16th Century, are available in Spanish (by Spanish monks and Mestizo historians like Duran and Tezozomoc) and in Nahuatl (Sahagún, Ms. de la Biblioteca Nacional de México). Collected after the Conquest, they base themselves, directly or indirectly, on Indian informants.

Not until recently, a renewed interest has been taken in these "intoxicating mushrooms".[2] In 1936 Robert J. Weitlaner discovered them still being used in ceremonies of the native *curanderos* among the Mazatec Indians in Huautla de Jiménez, State of Oaxaca, México. This discovery was followed by descriptions of non-Indians of Native mushroom ceremonies (Basset Johnson, Carrasco). However, only after the mycologists (the Wassons, Roger Heim) became interested, widespread scientific attention was aroused. Public interest awakened after *Life* magazine published an advance story from the Wasson's *Mushrooms, Russia and History*, with a picture spread of a mushroom ceremony in Oaxaca. Today, hallucinatory mushrooms are grown in greenhouses in Paris and their active substance is synthesized in Switzerland and the United States. Full-scale medical and psychological research programs are under way, among others, at the Institute of Personality Research at Harvard and the Universidad Nacional Autonoma de México.

By correlating Indian and quasi-Indian pre-Conquest references to hallucinatory mushrooms with personal experiences encountered today under controlled group conditions, we hope to reach new insights into one little known facet of pre-Conquest culture.

Types of Hallucinatory Mushrooms

To ward off the impending invasion of Cortés and his Spaniards, the Aztec emperor Mocteuczoma II sent out some of the best magicians of his vast domain. One group of them came from a series of towns famed for their wizardry, which are found on an imaginary line that stretches itself from east to west south of the Valley of

Mexico: Acapixtla (Yecapixtla today), Huaxtepec (Oaxtepec), Yauhtepec, Cuauhnauac (Cuernavaca), Ocuillan, Malinalco and Tenancingo.[3] Strangely enough, this line extended to the northeast leads to *San Pedro Nexapa*, on the slopes of the volcano Popocatepetl, and, drawn out to the west, to *San Pedro Tlanixco*, on the slopes of the Sierra de Toluca (Tzinantecatl). Stranger even, in both San Pedros hallucinatory mushrooms are gathered and used to this day. The third prominent "Mushroom village", already mentioned, is *Huautla de Jiménez*, which, located near Teotitlan del Camino and Tehuacan, Hes in another territory famous in pre-Conquest times for its wisemen, astrologers and magicians.

In each one of the three locations the mushrooms are slightly different in appearance: The one in Huautla is named *Psilocybe mexicana*, the one in San Pedro Nexapa, *Psilocybe aztecorum* Heim, and the one in San Pedro Tlanixco, *Psilocybe wassonii*.

The last mentioned variety is known to me personally and was used in the already mentioned group experiments. They are called by the natives *mujercitas* (little women) or by their Nahuatl equivalent, *Cihuatzitzintli*. They women selling me the mushrooms in the market told me that they had to take a few bites of the mushrooms while picking them, "because otherwise the *mujercitas* will get mad and we will fall sick".

Also used in native ceremonies, but according to Heim of no hallucinatory value, are *hombrecitos* (little men in Nahuatl: *tlacatzitzintli*) identified by the French mycologist as *Cordyceps capiate* and easily recognized by their phallic shape and *niños* (little children, in Nahuatl: *piltzitzintli*), a yellow mushroom known as *Nevrophyllum floccosum*.

Mushrooms in pre-Conquest Accounts

I have drunk mushroom wine, my heart cries,
I am desolate on this earth, I am a wretch...[4]

Thus a Nahuatl poet expresses his feeling of "Ephemeral Friendship". A feeling of desolation seems to he common to most pre-Conquest descriptions of the effect of intoxicating mushrooms. Orozco y Berra, writing in the 1870's but basing himself mainly on Motolinia, gives this account:

> The *teonanacatl*, divine flesh, divine mushroom, bitter and disagreeable, was eaten to practice certain superstitious acts; they took two of three only with a little honey. They produced a state of intoxication with frightening hallucinations.[5]

That these mushrooms were widely used is shown by the fact that Alonso de Molina, in his *Vocabulario en Lengua Castellana y Mexicana* in 1571 published for the first time, gives five different translations for the term "mushroom which makes drunk", namely: *xochinanacatl, tepexina nanacatl, ixtlauacan nanacatl, mazauacan nanacatl* and *tequinti nanacatl*.[6]

Often when disconsolate, dissolute, disintegrating states of personality are described, We find a reference to mushrooms in the Nahuatl accounts recorded by the Franciscan monk Bernardino de Sahagún. The following quotations are taken from their German publication and translation by Leonard Schultze-Jena. Only the first is from another source.

Of *yollopoliuhqui*, the deranged one, "the one who has lost his heart", it is sad: *iuhqui nanacatl tiquatinemi*, "you are like one who always 'eats mushrooms'".[7] The angry young man, in *tlaveliloc telpuchtli*, has turned into a mushroom, *nanacatl mochiuhtinemi*.[8] This is also said of the angry full-grown man, *Itlaueliloc tetzon*, who has turned into a mushroom, who eats them all the time, *nanacatl mochiuhtinemi, quiquatinemi*.[9] From the bad noblewoman without shame, *in amo qualli tetlapallo amo pinavani*, who is addicted to, mushrooms, *monananacatitinemi*,[10] it is only a short step to the prostitute, *aviyani*, who, besides drinking *mivintitinemi*, and chicle-chewing, *motlapavitinemi*, also has the vice of eating mushrooms, *monananavitinemi*.[11] The gallery of lesser members of society continues, downward, to the disintegrated young man, *telpuchtlavelitoc*, who also chews mushrooms consistently,[12] to the procurer, *tetlanochiliani*, who has a whole repertoire of effects for he acts like an hallucinatory seed, *tepixvia*, an enchanter, and an hallucinatory mushrooms.[13]

After having found references to them in the reporting of attributes among the lower fringes of society, we suddenly encounter a mention of them in Orozco y Berra's account of the coronation of Mocteuccoma II:

> The religious festivities ended, the lords gathered to eat woodland mushrooms, which contain that which confuses the mind, as if they were intoxicating drinks; while their minds were confused they saw visions, believed to hear voices; therefore, they took these hallucinations as divine notices, revelations of the future and augury of things to come.[14]

Orozco y Berra bases his accounts of the coronation on the descriptions by Durán and Tezozomoc, chroniclers writing in the 16th century. Durán says of the same incident:

> ... (they) were so intoxicated and out of their mind that many of them killed themselves by their own hands, and under the power of those mushrooms, they saw visions and had revelations of the future, and their demon spoke to them in their drunkenness.[15]

Tezozomoc has this to add:

> …the strangers gave them mushrooms found in the mountain woods so that they would get intoxicated, and with that they began to dance; others went inside to their rooms to rest. Then they took the big lights of the patio and everytime they started the song the strangers began to dance and to sing; and so that they should not be known they dressed themselves with false hair.[16*]

Mushrooms in the coronation festivities? Perhaps the *teonanacatl* was not so bad after all as a status symbol? The following text from Sahagún, the only report of an entire mushroom ceremony I could find written and preserved in Nahuatl, might throw a new light on the actual place taken by mushrooms in pre-Conquest Nahuatl culture.

Though not describing the coronation, it nonetheless is part of the important fiesta which the *pochteque*, the great merchants of the Aztec empire, gave the night before they sent their trading caravans to the distant, foreign commercial centers of the Gulf and Pacific coasts. For the Nahuatl text we have depended on the paleography of Leonard Schultze-Jena; the translation into English, keeping close to the original without romantic enlargement and verbal ornamentation, is our own:

> Ni man ye ic ualquiza im mihtotizque: in tlacateccatl in tlacochcalcatl, in ye mochintin quaquachicti, in otomi, in tiachcuau, auh; yehuantzin puchteca-tlahtoque ahmo mihtotia, zan onoque, mopistoque, ypampa ca yehuantzin in tecouachia. Auh in pochteca huehuetque, yehuantzin tenamiqui ysxochitica in ietica, in amacozcatl xiuhtezcayo, auh in ichquetzalli pepeyocyo metzcuitlatica. Uel yacattiuia, in tequeltitiloya, nanacatl; in quiquaya, ihquac, in quitouaya tlahtla pitzalizpan, ayamo tle tlaqualli quiquaya. Can oc iyo in cacauatl coniya youaltica.
>
> Auh in nanacatl neocyo in quiquaya; in ihuquac ye intech quiza nanacatl, in oncan mihtotia, oncan choca auh y cequintin inoc iyollo quimati: calaqui, in oncan inyeyan motlalian caltech, aocmo mihtotia, can oncan ualtolotimotlalia.

The Mushroom Party (translation of the text)

"The arrived those that were going to dance: the *Tlacateccatl*, the *Tlacochcalcatl*, and those that were going to abandon themselves, the *Otomi* and the *Titichcaua*. Those of the merchant leaders who were not going to dance were the straight-laced, chaste ones, who bought themselves somebody. And the old merchants met them with flowers, with tobacco, with brilliant green paper collars and bunches of quetzal feathers glistening in the moonlight.

Right at the beginning, as a refreshment, they ate mushrooms. Then they felt with it a bum, a red-hot blown fire inside and not from hot food they were eating. Therefore they drank cocoa that was kept warm for the night. Thusly they ate the intoxicating mushrooms.

When they had finished eating them, they danced and they cried. Meanwhile some of them felt the effect: they went inside they sat down, with their backs against the wall. They didn't dance anymore. They sat by themselves, in the same place and let their heads hang.

In that stupor, some imagined they were going to die and they cried; some were to perish in the war; some were to be eaten by wild beasts; some were to take prisoners of war; some were to be somebody rich, very rich; some were to buy and be owners of slaves; some were to be adulterers, were to be stoned, were to be stoned to death; some were to be thieves and be stoned to death; some were to become dissolute, were to end as drunkards; some were to drown; some were to be somebody peaceful, peacefully living to themselves and dying the same way; some were to fall from the roof and die suddenly.

There were many who were speaking to themselves as they saw how were they were to perish. And as the mushroom effect wore off, they met, huddled together to talk: the ones who had been in the stupor and those who had not eaten any mushrooms who hadn't been in the stupor - and those were teasing the others all night long about what was going to happen: that they were perhaps thieves, that some of them were adulterers. There were so many things to pique them with: that one was to capture prisoners, the great works another was going to do; that one was to be a leader among the young men; that one was to die in the war; that one was to be captured; that one was to be rich; that one was to be successful with women; that one was to wash slaves for sacrifice; that one was to be an adulterer; that one was to hang himself; that one was to drown; that one was lo become dissolute. There were many of those that were teasing... And lo themselves they imagined that they might go lo their deaths in that far land..."

Mushrooms Today

The two mushroom experiments in which I took part were undertaken at different times, in different locations and in different group situations. Both limes the *mujercitas* from the slopes of the Sierra de Toluca were used. The first experiment look place in the midst of the rainy season, in August; the second, towards its end, in October. Fresh mushrooms are available only during the rainy season.

On Thursday, market day, the first lot of mushrooms was bought from Doña Juana, who sampled them in front of us, in the shade of a churchwall, away from the tumult of the market. Upon the return lo Mexico City, the mushrooms were washed in cold water. Since it wouldn't be till Saturday that all subjects could meet for the group session, they were kept till then on the center shelf of the refrigerator.

The experiment took place in a residence in Cuernavaca, forty miles south of Mexico. This city of "eternal spring" has a subtropical climate and an average, even temperature in the middle 80's. Throughout the experiment the usual atmosphere of the house was maintained. After an afternoon of swimming, the participants wore either sports clothes or swimming suits. Though surely a far cry from Aztec vestments, the attire offered probably the same freedom of movement as the *maxtlatl* and the *tilmatli* of the Aztec merchants and noblemen. The idea was to experience the mushroom effect in the usual informal occidental group situation, with the least possible changes.

At 17.00 hrs., I began eating eight of the bluishly tinted mushrooms measuring on the average 7 cm. in stem length and 4 cm. in head diameter. Their taste was bitter-sour and left an acrid afterburn on the tongue and in the esophagus. I was seated at a garden table on the terrace. The large parasol above me had its underside covered with a tasteless flowerpattern. FoHowing my line of vision, about 2 m. beyond the table was a low hedge, then the length of the swimming pool. Farther on, 10 m. of lawn was followed by a line of trees forming the property line. It was about one hour before sunset.

After almost an hour I felt a slight, short pain in the nape of my neck. This was followed soon by a hardly noticeable increase in color perception. At about 18.10 hrs. I thought I saw some of the flowers in the pattern of the parasol move. At the same time I felt an extreme lightness and, coupled with it, a tendency to laugh. My eyes started watering and I had to visit the bathroom inside the house.

After I returned to my seat, I fixed my eyes on the fork in the tree at the end of my line of vision. Soon it took on the shape of a mask, hut not in the sense that it was obviously a mask, but much more that one was reminded of one - about the way one is reminded of something or other in the shape of the inkplots of a Rorschach test. This seems to be a very important point to note: Reality does not change completely while fixing the eye on a certain object. It is much more a seeing of forms based on the concrete image, or integrated into it. Soon afterwards the tree became the corner pillar of a kind of arcade, which changed continually its appearance. Suddenly, I noticed that I could return to the reality of my "table environment" at this side of the hedge. The table was still the table with its glasses and the parasol overhead. And when I looked beyond the hedge... my tree became once more the corner of that marvelous arcade. The images in it were rapidly changing, composite patterns, comparable with finely made mosaic or an exquisite stained glass window. The entire situation appeared closest to sitting in a drive-in theater: One can lose oneself in the image on the screen, but can also return to the reality of the confines of the car: to the coke on the dashboard and the box of popcorn.

At about that time an assistant put a portable radio in front of me. (Who had any idea of time?) Possibly the music might influence my visions. It didn't work. The radio music sounded tinny, grating, out of place. I wanted to be alone with my patterns.

I changed my point of concentration to the parasol above me and now its underside became my world of beautiful imagination. Within its circle, moving harmonically, changing consistently, appeared the most unusual designs of extremely brilliant, integrated colors. There literally thousands of them, one more perfect than the other. In their forms, not in their content, they reminded one of Mixtec codices. All was pure enjoyment. Later on I was told that I sat for an hour and a half staring at the parasol above me.

Another desire to urinate made me leave my position on the terrace. To enter the rest of the house, I had to pass through the kitchen. I noticed a pastel overcast in the interior. Otherwise, neither my visions nor my motions seemed impaired. The assistant who had brought the radio met me and said, "you should see how Ben is carrying on in the bar". Indeed, there seemed to he a clopping, singing sound in the bar-recreation room. As I entered the bathroom I was startled by the extreme luminescent brightness of a maroon towel hung up to dry. Also, the tile room seemed to be alive with hidden fluorescent light.

Then I went to the bar and saw my friend Ben sitting alone in an easy chair. The guitar laid across his knees, he was holding a nonsense dialogue interspersed with nonsense rhymes - with his barret. He recognized me immediately (there was never any difficulty in returning to the reality of recognition) and said, "You know what I just found out? A guitar, like a human being, has a musical side... " Here he struck the cords. Then he flipped the instrument over and tapped the bottom, " ... and a drum side". Then he went into an explanation of the different opportunities of influencing human actions by using either the musical or the drum side of a guitar. At that instant I noticed that also to my repertoires of feelings a new perception of symbolic in human situations had been added.

Leaving Ben, I went to one of the bedrooms. Three other participants were lying on the beds, hallucinating. They appeared to be completely happy with themselves. Now and then a low chuckle might be heard. Lying down also, in the darkness of a night outside, I noticed that now I could turn lo the hallucinations "inside me" at will, being able to change back with equal ease to the actual surroundings. Even while sinking away to see my "inside patterns", I could feel the texture of the bedspread with my fingers. My visions now consisted mainly of ribbons of the republics' flags: French, German, Mexican and American.

Between spells of being absorbed in my patterns, I had an interesting experience of symbolic perception. On the bed next to me, a coed, college senior, was lying in a bundled-up position. Next to her a professor from a prominent university, quite her senior, stretched out full length. Suddenly, with considerable impact, I saw the situation as a symbolic relationship: The phallic posture of the father figure next to the womb position of the child... I might add, that mushrooms don't seem to have any aphrodysian qualities.

After some more time in the bedroom I returned to Ben in the bar. He was still conversing with his barret in a completely autonomous attitude. Then, for the first time I noticed that objects had took on a *melted* look, but through conscious effort they could be kept *solid*. Only their *halo*, an aura of pastel color, could not be forced away.

Soon the effect began to wear away. It had be en just about five hours since it set in. There were still waves of distorted perception, especially of colors. Then, abruptly, I was completely *back*, feeling purged somehow and hungry. There remained a lingering, heightened color awareness. Other wise, I felt no after effect or hangover. I thought only to feel a slight pain on my eyeballs, as after looking into bright sunlight. Eats and drinks were brought to the table. All participants *returned* one after another and began talking about their experiences. In this respect, nothing was changed from pre-Conquest times.

Exchanging impressions and adding information supplied by the assistants, the following pattern of mushroom effects established itself: 1) The effect sets in approximately an hour after the eating. 2) It is felt first by a change in color perception and a general relaxation. This leads to feeling happy to ridiculous and a loosening of the sphincters, mainly inducing a watering of the eyes. 3) The first hour or more is one of intense hallucination in a more or less catatonic state. 4) The quality of the hallucinations is completely subjective, seeming to depend on the psychological state of the person. 5) There seems to be no feeling of hostility. There might be manifestations of auto-sufficiency, a desire not to be bothered. If potential conflict situations arise, the tendency is to withdraw. 6) There occurred definitely no schizophrenic state. All subjects had absolute control over their actions, whenever necessary. (It should be investigated to what extent this holds true for the quasicatatonic state already mentioned). 7) There is absolutely no difficulty in communicating verbally,[18] though the sense of auto-sufficiency is such there is no or little desire for verbal communication. 8) There are no side or after effects worth mentioning.

The second experiment took place in a residence in a Mexico City suburb, in October. This time the mushrooms were eaten the same day they were bought in the Valley of Toluca. The effect was basically the same. The quasi-catatonic state at the beginning was less pronounced and shorter. A certain harmony with sound effects was achieved by listening to Handel's *Watermusic* played back on tape. The over-all experience was pronouncedly wavelike: periods of almost complete reality changing with waves of hyperreality and distorted color perception. There was an extremely heightened awareness of symbolic values in inter-human relations. Toward the end of the toxic state, I experienced for first time a morphic change of my hand: the skin seemed extremely pergamine, the hairs prominent and the fingers growing and shrinking. The effect occurred only after watching the hand for some time. It could he "cut off" at will without difficulty.

It should be noted that during the second experiment all participants spoke at least three languages with some fluency. (The first session was carried on in English). There was absolutely no difficulty sustaining verbal communication in whatever language seemed most convenient at the moment.[18]

Conclusion

A comparison between pre-Conquest accounts and present day experiences shows on the surface a considerable similarity of overall effect. There is, however, a trend toward exaggeration in the Spanish and Mestizo chronicles. Closest to the effects encountered today comes the Nahuatl text about the *pochteca* party, collected by Sahagún.

Attributive expressions, involving references to mushrooms, also preserved in Nahuatl, may not mean a condemnation in pre-Conquest society as such. They are most likely used to create a strong image and evoke the intensity of the effect which must have been known widely - as is shown by the presence of five words for *intoxicating mushrooms* in the Molina vocabulary.

Since it was not meant for general publication, the *Pochteca* account seems to have preserved a considerable objectivity of relation. In the Spanish and Mestizo descriptions we are dealing with writings for wide publication, if not for propaganda. Therefore, they are in accordance with the opinion of the Catholic hierarchy that effect that cannot be controlled should not be approved. This explains also the emphasis on horrible visions and excessive acts. In tum, the *pochteca* report gives the whole range of the effect.

Three points seem to arise dearly from the comparison between pre-Conquest accounts and present-day experiences: 1) Nahuatl records are much less discolored and exaggerated than those written in Spanish; 2) in order to view manifestations of Nahuatl culture an undistorted, "humanistic" outlook is prerequisite and 3) we should try to comprehend pre-Conquest culture from within its context, perceive the complexity of its structure and should never accept without severe questioning, or take for granted the value judgments made by opinionated observers hundred; of years ago - or even just yesterday.

When I was asked during the toxic state, I and difficulty recalling the German word for *pea* (*Erbse*) and could think sooner of the Spanish *chícharo*. A perfectly natural lapse of memory which might also have happened any other time.

Mushroom and Religion

by

Robert Graves

original source: http://www.math.uci.edu/~vbaranov/nicetexts/eng/mushrooms.html

The profound importance of mushrooms in primitive religion had remained undetected until some twenty years ago, when Mr. R. Gordon Wasson, an American banker, and his Russian-born wife Valentina first called attention to it. The new science of ethnomycology, meaning the attitudes of different races to mushrooms, began with the Wassons' puzzling over the division of Europe into two distinct camps: mycophobes (nations traditionally afraid of mushrooms) and mycophages (nations addicted to eating them). The mycophages of Europe are found in Spain, Southern France, the Balearics, Bavaria, the Balkans and Russia. Russians are the greediest mushroom eaters and recognize over ninety varieties of edible ones.

Until recently we English ate only the white field mushroom *Psalliotis campestris*, except in the Midlands where blewets were sold in the markets. But as a boy in North Wales I found even the field mushroom avoided as poisonous.

My mother had spent her childhood in Bavaria where mushrooms grew profusely in my grandfather's pine woods, and when taken there for holidays as a child I soon learned to distinguish seven or eight edible varieties and bring them back to the kitchen for dinner. Home in Wales, I came across some of these same mushrooms growing in the woods and brought them back to eat; but my mother astonished me by shouting: 'Throw those toadstools away at once! Yes, I know that they *look* like the ones we ate last week at Lauzforn, but here they are deadly poison. You had better wash your hands!' Whether she really believed this - her view seemed borrowed from my mycophobic Irish father - or whether she had to take this attitude because the cook would give notice the moment they were brought into the kitchen, I have never decided.

The existence of so many million unreasoning mycophobes throughout Northern Europe and North America - though, to be sure, some of them now dare to accept cooked mushrooms from abroad, neatly bottled - reminds me of another curious taboo in force among the ancient Greeks. They were forbidden to eat any bright red food, such as lobsters, crabs, prawns and wild strawberries (which had no name because regarded as poisonous). The Hebrew word *syeg*, meaning a 'hedge', explains both these taboos. To protect the Biblical ban on, for example, buying or selling on the holy Sabbath, the Jews of Jesus's day had put a protective 'hedge' around the Fourth Commandment by forbidding anyone to carry coins on his person from Friday evening until Saturday evening. And the truth is that mushrooms had once been regarded as holy and reserved for priests, kings and other privileged people; therefore to prevent the unprivileged from eating a sacred mushroom; a general *syeg* was put on mushroom-eating and reinforced by treating all mushrooms as poisonous. However, as already mentioned, an unexplained relaxation of the taboo in England allowed the eating of white field mushrooms, though the most deadly European mushroom of all, the *Amanita phalloides*, with which Nero's stepfather the Emperor Claudius had been poisoned, was equally white and has often been mistaken for it. It is therefore reasonable to guess that the sacred mushroom originally protected by these taboos grew in forests, not in fields, and was scarlet; and that the taboo explains the diabolic or disgusting names given even to highly edible other mushrooms.

But why was the scarlet mushroom (which can be easily identified with the white-spotted one now favoured by red-coated gnomes in suburban gardens and also associated with Father Christmas's reindeer and decorated tree) held sacred? This spectacular mushroom, incorrectly rumoured to be deadly poison, grows by the million all over the British Isles, but only in birch forests. A simple answer is that this was the magical mushroom, on which sat the caterpillar smoking his hookah, that Alice found growing in Wonderland. Lewis Carroll had read about its properties not long before he published the book; they included the same hallucinations about height - 'curiouser and curiouser' - from which Alice suffered after nibbling it. This mushroom, named *Amanita muscaria* - popularly 'fly agaric' - has now been proved by Gordon Wasson's detailed examination of the Vedic hymns (written in Sanskrit about the time of the Trojan War), to have been the Food of the Gods. It is there named 'Soma'. That it is also 'Ambrosia' and 'Nectar' (both these words mean 'immortal') which were famous as the food and drink of the Greek Olympian gods, I had myself shown some twelve years previously. Two early Greek poets, Sappho and Alcman, had preserved the ancient tradition of Ambrosia as a drink, not a food. This was because the juice of the mushroom - which lost its virtue when cooked - was squeezed out of it between boards, then mixed with milk or curds; and the pulp was thrown away. According to these Vedic hymns, Agni, the god of mystic illumination and holy fire, who was also expressly identified with Soma, had been created when the Father God Indra threw a lightning bolt at the Earth.

Dionysus (Bacchus), the Greek god of mystic illumination, was similarly born when his father the God Zeus (Jove) threw a lightning bolt at the Earth Goddess Semele; the bolt killed Semele but her child was saved and sewn up in his father's thigh, whence he was later granted a second birth. Dionysus is said to have eventually conducted his mother to Heaven where she changed her name to Thyone, meaning 'Queen of the Maenads' (or raging women) and presided over Dionysus's ecstatic October festival, called The Ambrosia. October was the mushroom season. The effect of the *Amanita muscaria* taken without other intoxicants is to give the taker the most delightful hallucinations, if he is in a state of grace, but horrible nightmares otherwise. Fortified, however, with beer and the juice of yellow ivy it would send Greek men and women raging mad. A mixture of *Amanita muscaria* with whisky has long been used as a celebratory drink by successful salmon-poachers in Scotland. It is called a 'Cathy', in honour of Catherine the Great of Russia who is said to have been partial to it.

The pre-Classical priests of Dionysus, a god now known to have been active in Mycenean times, seem to have claimed the sole rights in the scarlet mushroom, the memory of which they had brought from their original homes in Central Asia and which is not found growing south of the fortieth parallel, except at a great height and always in birch groves. The Vedic priests of Agni seem to have imported their supply from the birch-groves of the high Himalayas. Throughout the world mushrooms were believed to be begotten only by lightning.

That Dionysus was Ambrosia, as his Indian counterpart Agni was Soma, is proved by the legend of his birth from Zeus's thigh. The Vedic hymns make it clear that the priests of Indra and Agni used the two different ways of taking Soma still found among the Paleo-Siberians called Korjaks, and also in a small Mongol enclave of Afghanistan. The first was a simple drinking of the juice pressed from the mushrooms between boards and mixed with milk or curds. The hallucinogenic *indoles* it contained entered the stomach; but a great many more entered the kidneys and were later discharged with the urine. Clean-minded Classical scholars have until now shut their eyes to the possibility that the Vedic hymnwriter may have meant exactly what he said with 'the great gods piss out together the lovely Soma'. Yet it has been known for at least two centuries that the Korjaks do so after drinking the mushroom juice, and that their friends strain the urine through wool and, after drinking it, enjoy the same ecstasies. And this, of course, explains Dionysus's second birth from the thigh of his father Zeus and his subsequent release to worshippers in a stream of hallucinogenic urine. Yet Dionysus's source of intoxication has always been politely attributed by Greek scholars to wine, and Ambrosia is identified in the *Oxford English Dictionary* with *asclepias* (milk weed); and by various Encyclopedias with almost every sort of plant except mushrooms.

The Norse *berserks* were magicians and sages, and seem to have used the scarlet *Amanita muscaria*, as did the Korjaks, for inducing prophecies. They were called Berserks (Bear-shirts) because they worshipped the Bear goddess, which accounts for our Great Bear constellation, and wore bear skins in her honour. Their cult was suppressed in the eleventh century A.D. by Christian converts, not only in Scandinavia but in Iceland, where dwarf-birches in the centre of the island provided the berserks with their *amanita*. The proverb quoted by the Emperor Nero 'mushrooms are the food of the Gods' was true in the sense that they provided the passport to a Paradise from which the mushroom-eater was permitted to return, like a god, after his celestial visions. Yet Nero who, having been excluded from the Eleusinian Mysteries for murdering his mother Agrippina, had not himself visited Paradise, quoted the proverb only in a mocking sense: for his step-father Claudius, after dying from *Amanita phalloides* poisoning administered by Agrippina, had afterwards been deified.

I have eaten the Mexican hallucinogenic mushroom *Psilocybe heimsii* in Gordon Wasson's company, with the intention of visiting the Mexican paradise called Tlal6can to which it gives access. The god Tlal6c, who was toadheaded, corresponded exactly with Agni and Dionysus. I also wanted to know whether I had been right in supposing that all religious paradises except the Christian (which is based on a first century Eastern potentate's court), such as the Hebrew, the Sumerian, the Indian, the Mexican, the Polynesian and the Greek (known as the Garden of Hesperides) were not only very much alike but corresponded also with the individual paradises seen by such mystics as the English poet Henry Vaughan, the Silurist. The word *paradise* means 'orchard' in the Semitic languages; an orchard-garden of fruit trees, flowers and running water. Yes, I had guessed right, though there are, I believe, certain dissimilarities: for instance, elephants appear in the Indian paradise and in others the inevitable serpent, familiar to readers of the Paradise chapter in *Genesis*, may appear as it did for me, as an intricately patterned gold chain. A bright snake-like formation is, by the way, a common symptom of a cerebral deoxygenization induced by hallucinogenic drugs; and seeing snakes is a common occurrence among alcoholics, saints who starve themselves, drowning sailors and sufferers from meningitis. My experiences included not only an orchard Paradise where one can see sound, hear colours, and watch trees growing leaf by leaf, but a paradise of jewels like that described in the *Book of Ezekiel* XXVIII, 13-14.

The *psilocybe* mushroom used in the Mexican rites is small, brown in colour, slender-stalked and bitter; but sculptural evidence from Central America suggests that it had supplanted the *Amanita muscaria* in ritual use, probably because it was easier to obtain and because the hang-over did not last so long. The same change seems to have occurred in Greece: the discovery of a new hallucinogenic mushroom, a *stropharia*, or a *panaeolus*, which, unlike the *Amanita muscaria*, could be ground up and baked in sacrificial cakes for religious use in the Mysteries without losing its powers. When, according to the Greek myth, the Corn Goddess Demeter visited Eleusis, the Attic city where the Mysteries were to be celebrated for another two thousand years, she is said to have ordered Triptolemus, son of the local King, to drive around the civilized world in a chariot drawn by snakes, spreading the arts of agriculture as he went. This myth is clearly deceptive. Corn had been sown and harvested in Palestine for several thousands of years before Demeter's people arrived at Eleusis. What may have happened is that the local priestess sent a message about the newly discovered mushroom to priests and priestesses throughout the civilized world - hence the snakes in Triptolemus's chariot. This, if so, would explain why the nature and source of the original Soma has been forgotten in India for so many centuries. The supply from the birch groves of the High Himalayas seems to have been cut off by enemy action, and *placebos*, such as *asclepias*, substituted for it until eventually its place was taken in Brahman ritual, after the receipt of Triptolemus's message, by a better, more manageable and more accessible sacred mushroom.

In 1957 at my suggestion Mr. Wasson and the famous mycologist Dr. Roger Heim, Director of the Musee de l'Homme at Paris, visited the New Guinea Highlands from whence had come reports of a mushroom cult. They were able to attend a Bird of Paradise courtship ceremony danced by Stone Age men and women under the influence of a sacred mushroom. The specimen that Wasson and Heim were offered proved, however, unhallucinogenic. This may have meant either that the tribal elders deceived their visitors for religious reasons by giving them some ineffective substitute or that the tribe, having emigrated there from a place where a truly hallucinogenic mushroom grew, had been reduced to using this other variety as a *placebo*.

Another variety of the *Amanita muscaria* grows south of the fortieth parallel, with the pine as its host-tree, and is equally hallucinogenic. That it was ritually used in Biblical times is suggested by an unwritten Hebrew taboo on mushrooms, broken only by the non-orthodox. (Arabs, by the way, are mycophagous, which perhaps accounts for mushroom eating in those parts of Southern Europe occupied by the Saracens during the early Middle Ages.) I have elsewhere suggested that the golden 'ermrods' laid up in the Ark together with a pot of hallucinogenic manna really represented sacred mushrooms. A concealed reference to their use appears in the *Book of Judges*: the unlikely story of how Samson collected three hundred foxes and sent them into the Philistine's cornfields with torches tied to their tails. The Palestinian fox is not gregarious and the task of capturing three hundred of them, at the rate of one or two a day, and feeding them all until he had collected the full number would have been a senselessly exhausting one. Besides, how could he make sure that the foxes would run into the cornfields and keep the torches alight? The truth seems to be that Samson organized a battalion of raiders - three hundred was the conventional Hebrew battalion strength, as appears in the story of Gideon - and sent them out with torches to burn the Philistines' corn. Indeed, in the 1948 Jewish War of Liberation a raiding battalion was named 'Samson's Foxes'. But why foxes? Because the juice of the *Amanita muscaria* mushrooms (which still grow under the pines of Mount Tabor) could be laced with ivy juice or wine to make the raiders completely fearless, and because this variety, when dried, is fox-coloured. So are other mushrooms, such as the popular *chanterelle* which the Russians call *lisichka*, 'little fox'; but to clarify its meaning the Bible specifies 'little foxes with fire in their tails'. In the *Song of Solomon* the Shunemite bride, about to take part in a sacred marriage, urges her lover to fetch her 'the little foxes that spoil the vines, for my vines have tender grapes'. She means that Solomon must fortify his manhood with mushroom-juice laced with wine, the better to enjoy her young beauty.

Why mycophobes called mushrooms 'toad's bread' or 'toadstools' can readily be explained. When the toad is attacked or scared the warts on its back exude *bufotenin*, the poison secreted in the white hallucinogenic warts of the *Amanita muscaria*. In ancient Greece the toad was the emblem of Argos, the leading state of the Peloponnese, the emblems of the two other states being also connected with the mushroom: namely fox and serpent. This division into states had been made by a legendary king named Phoroneus, which seems a form of Phryneus, meaning 'Toad-man'. The capital city was Mycenae ('Mushroom City') said to have been built by Phoroneus's successor Perseus ('the destroyer') who, according to Pausanicus, had found a mushroom growing on the site beside a spring of water. The toad was also the emblem of Tlalóc, the Mexican God of Inspiration, and appears surrounded by mushrooms in an Aztec mural painting of Tlalócan, his Paradise.

The Slavs are not mycophobic, probably because their remote ancestors were nomads on the treeless steppes and unacquainted with *Amanita muscaria*. Their fermented mare's milk, called kavasse, satisfied their need for occasional intoxication. Like the Arabs in their desert poverty they had learned to eat any growing plant or living animal that was not poisonous. Bavaria is mycophagous, while the rest of Germany is mycophobic, simply because it was once invaded by Slavs.

I should add that reindeer are known to get high on *Amanita muscaria* in the birch forests of the far North, a habit of which their owners take advantage.

The Case for Challenging Research and Value Systems

"Who Was the First Magician?" - Foreword by Christian Ratsch

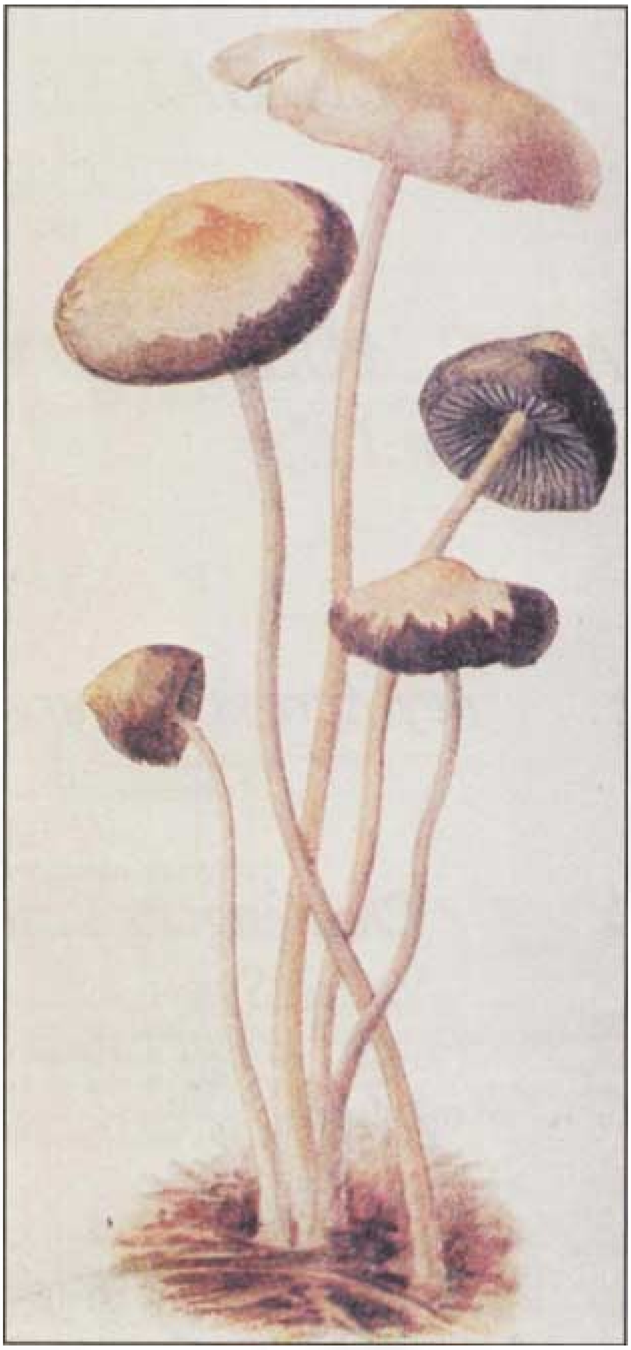

Figure 1 - Water Color Painting of *Psilocybe semilanceata* (Germany, 1927)

Nobody knows precisely when the first magic mushroom emerged from the shadows of prehistory to enter the light of consciousness. Nobody knows when the first magic mushroom was eaten by a human being. Nobody knows just who the first magic mushroom eater was. In seeking answers to these questions, we can only speculate. Mycophobes, however, are quick to voice their conviction that only a fool would be reckless enough to want to attain a higher state of consciousness beyond the boundaries of everyday reality. And only a fool would attempt to do this by ingesting those odd little things that mysteriously thrive on decaying, humid soil, rotten wood and malodorous mounds of cow manure. Historically, magic, mushrooms have been feared and hated' since antiquity: magic mushrooms were thought to be made from poisons that had dripped from serpents' fangs; they were considered to be unclean emissions of evil spirits; moreover, mushrooms were a known cause of death and disease, bloated stomachs and insanity. Beliefs such as these have survived to the present day. They persist, for example, as figures of speech, such as the slick Austrian description of a societal misfit as someone "who ate those madness-inducing mushrooms."

But, there is another, very different, magic mushroom legacy as well.

Flesh of the Gods for Devil Worshippers

The Old World. Mycenaean civilization began with a mushroom trip - Mushrooms were an ingredient in the ambrosia of Dionysus. Porphyrius, the fourth century Latin poet and contemporary of Emperor Konstantin, knew that magic mushrooms were the children of the gods. A quasi-cannibalistic ritual, the act of eating the children of the gods unlocked one's power to experience the truly divine. But not all mushrooms enable human beings to enter the realm of divine consciousness. This magic power resides in only those fungi known as "fool's mushrooms", which were considered poisonous and believed to be the spawn of the Devil throughout the late Middle Ages and well into modern times.

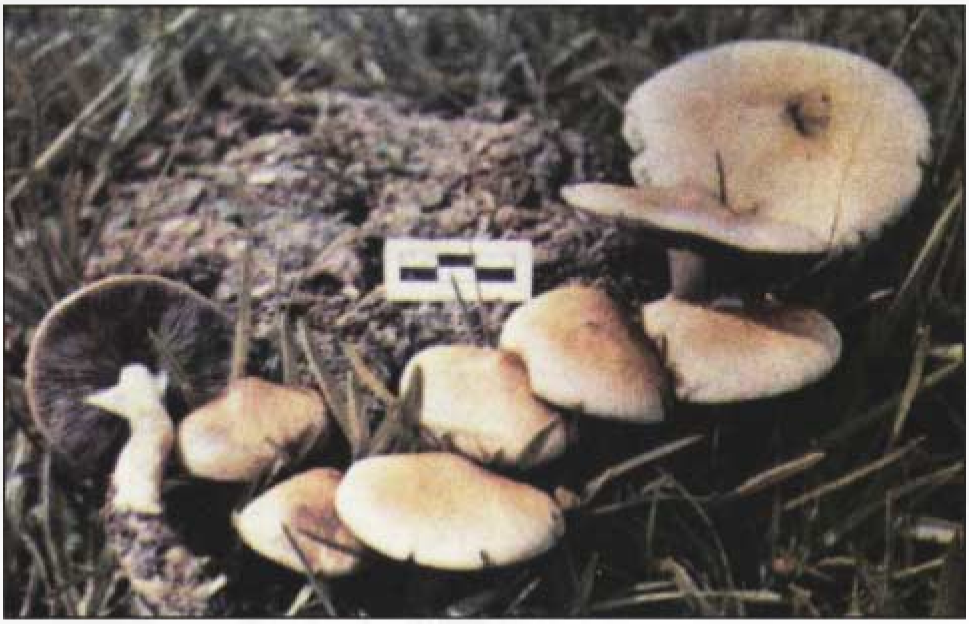

Figure 2 - *Psilocybe cubensis* from Australia

The New World: The Aztecs in Mexico referred to a number of small, inconspicuous mushrooms as teonanacatl, or "flesh of the Gods." These sacred mushrooms were eaten during the course of rituals intended to contact the Gods in order to learn about the world and the realm of the divine. These magic mushroom rituals thoroughly spooked the Catholic Spaniards. The mushroom eaters, commonly thought of as Devil worshippers, were hounded by the Inquisition. Still, all good things survive the tests of time, so the cult of magic mushroom eaters did not become extinct. Like mycelia underground, the cult continued to flourish, and at the proper time in recorded history, in 1957, the fruit of the fully grown mushroom re-surfaced to draw widespread public attention. Valentine and Gordon Wasson became the heroes of the modern neo-mycophilic movement.

Back to the Old World: The revelations and insights gained from the use of psychoactive mushrooms were so magically wonderful, that our native European "fool's mushrooms" - which were gene; considered inedible - had to be recognized as closely related to the magic mushrooms of Mexico, the flesh of the Aztec Gods. The souls of magic mushrooms in Mexico and Germany are essentially made from the same substance: psilocybin.

Jochen Gartz has made an extraordinary contribution to the field of mycology by embracing Germany's magic mushrooms and the scientific study and testing of these fungi. The research efforts upon which this book is based require nothing less than a fearless, brave and courageous consciousness, free of prejudice and mycophobia. I am convinced that a researcher's consciousness infused by the spirit of the magic mushroom is capable of far deeper scientific insights than we can ever expect from the usual ivory tower academics, isolated from reality, and who gorge themselves on our tax dollars.

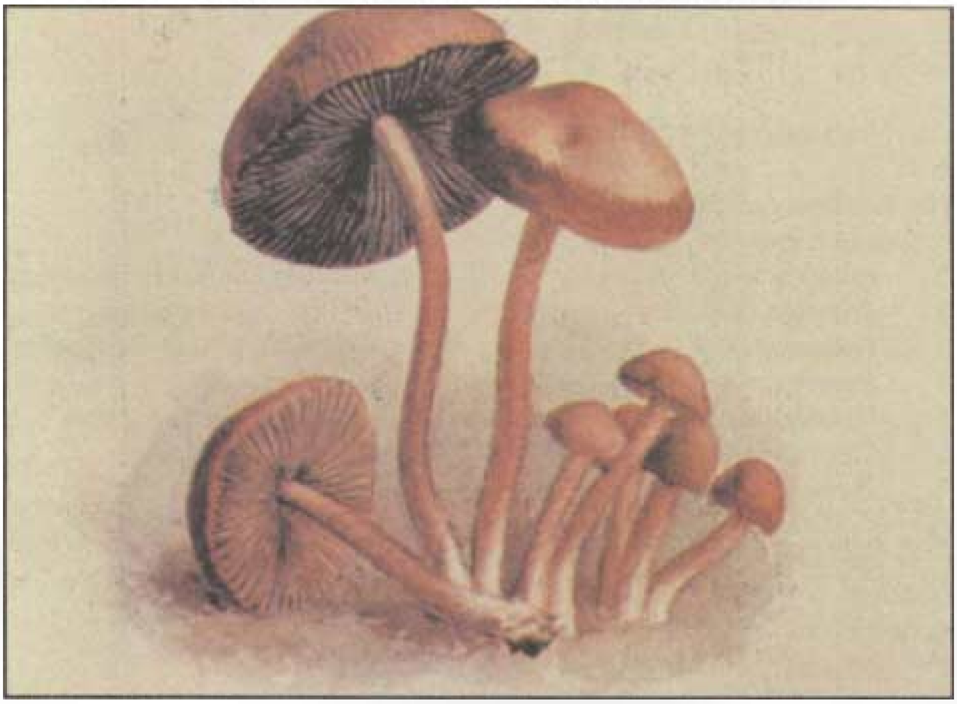

Figure 3 - Water color painting of *Panaeolus subbalteatus* (Germany, 1927).

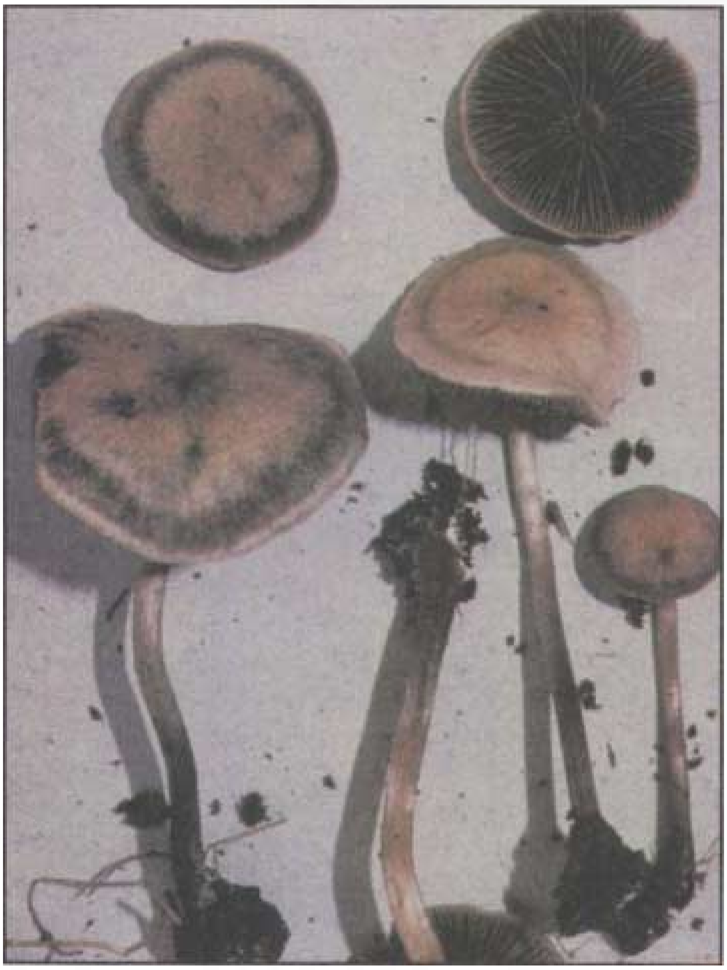

Figure 4 - Fresh *Panaeolus subbalteatus* mushrooms.

I met Jochen Gartz shortly after the fall of the Berlin Wall at the third symposium of the European College for the Study of Consciousness (ECSC) in Freiburg, Germany. Our encounter was my first contact with a researcher from the former East Germany. Jochen Gartz's enthusiastic lecture was a truly consciousness-expanding event, his words breaking down traditional borders and crossing over into new territory. The magic mushrooms spoke through him - with no trace of dogma or ideology - in the tradition of true anarchy that is the hallmark of mushroom magic. What I heard was unbelievable. Jochen spoke of a "new" psychedelic mushroom and its migration. The mycelia had spread in concentric circles outward from Leipzig, jumping all political borders. Finally, when the mycelia reached West German soil, the hated Berlin Wall crumbled. Could there possibly be a connection between the evolution of the magic mushroom and the evolution of our consciousness? Could a mushroom have contributed to the resolution of our political conflicts?

In the past, politicians, even popes, had their own jesters and magicians, who functioned as pressure release valves in the machinations of political power struggles. It is obvious that a country whose chancellor is being pelted with eggs, urgently needs a new breed of magician who are able to readjust reality. But today, no aspiring magician should go about this task without this book as a guide for the wondrous journey into the realm of magic mushrooms.

CHAPTER 1
Introduction

I BELIEVE THE TIME HAS COME FOR A COMPREHENSIVE REVIEW OF NEW FINDINGS FROM THE FIELDS OF MYCOLOGY, TAXONOMY AND NATURAL PRODUCTS CHEMISTRY

When R.G. Wasson, R. Heim and A. Hofmann began their interdisciplinary research program to study the Mexican species of mushrooms and their usage in Mexican mushroom cults, their efforts culminated in a 1958 landmark report that described the isolation, molecular structure and synthesis of the mushrooms' active ingredients: psilocybin and psilocin. Several years later, these substances were also identified in a species of mushroom in Europe, *Psilocybe semilanceata*, which became the first in a series of newly discovered species. Since then, psychoactive mushrooms from other genera have been reported with increasing frequency.

As part of my analytical work dedicated to the identification of naturally occurring chemicals, I had the good fortune to be part of a research team that studied alkaloids found in a variety of mushroom species. Now I believe the time has come for a comprehensive review of new findings from the fields of mycology, taxonomy and natural products chemistry. Wasson and his successors have already provided detailed accounts pertaining to the history and study of the Mexican mushroom species, so that these materials need not be repeated in this context. However, certain aspects concerning the more recent uses of these mushrooms as well as their conditions of growth will receive more detailed attention in later chapters.

The main purpose of this book is to inspire further study of these mushrooms, particularly basic research efforts and medical applications of magic mushroom ingredients.

The extensive bibliography will help scientists and other interested mycophiles to further immerse themselves in this complex area of study.

CHAPTER 2

Reflections on the History and Scientific Study of Magic Mushrooms

It is remarkable that cultures native to the American continent knew about a relatively large number of natural mind-altering substances compared to early cultures that evolved in Europe or Asia. Botanical evidence does not support the notion that Europe is home to fewer hallucinogenic plants than other regions. Furthermore, the growing number of recently discovered European mushroom species containing psilocybin indicate a flourishing psychotropic mycoflora in Europe similar to those found in other countries.

It is unlikely that early European cultures learned less about local plants and mushrooms through usage and experience than cultures elsewhere in the world. Most likely, early cultural knowledge of European psychoactive plants and mushrooms was lost or destroyed at some time in history, probably as early as several hundred years ago.

The discovery that the fly agaric mushroom (*Amanita muscaria*) was known for its psychoactive properties in Siberia invited the conclusion that this mushroom was used as a psychotropic agent in medieval Europe as well. In fact, there is very little evidence from the Middle Ages to indicate widespread knowledge of the effects of specific mushrooms on human consciousness. However, I believe that past reports on psychoactive mushrooms were causally linked to *Amanita muscaria* simply because this was the only known psychotropic mushroom in Europe at that time.

While the usage of *Amanita muscaria* among Siberian tribes has generated reports of spectacular hallucinations, European accounts of fly agaric intoxications do not generally include descriptions of such intensely hallucinatory effects.

Accordingly, the potent hallucinogenic effects of specific *Psilocybes* and related species are likely to have had a much more significant influence on early European cultures than the delirium-like visions induced by *Amanita muscaria*, a species that is also known to induce unconsciousness and severe somatic side effects. This hypothesis is corroborated by data from comprehensive field studies conducted in Mexico. I believe that historic accounts including those described below - indicate a knowledge of and familiarity with psychotropic mushrooms in Europe that is most likely derived from usage of *Psilocybes* and related species, rather than experience with *Amanita muscaria*. However, it is extremely difficult to reject or confirm this hypothesis, due to the lack of conclusive data available for analysis today.

Bwyd Ellylon: A Feast of Fairies in Celebration of the Spirit World

Tales of ritualistic mushroom usage have found their way into the realm of myths and legends. For instance, one legend describes a peculiar poisonous mushroom in Wales (British Isles) with the strange name of *Bwyd Ellylon*, which was considered a delicacy by fairies feasting in celebration of the spirit world. *Psilocybe semilanceata* is the most important psilocybin-containing mushroom in Europe and it thrives in parts of Great Britain, where the mushroom grows abundantly all across the Welsh countryside during fall season.

I would like to thank G. Samorini for pointing out that the Inquisition was unusually cruel and vicious in the Alpine valleys of Valcamonica, Valtrompia and Valtellina (located in the provinces of Brescia and Sandrio in Northern Italy). Many books chronicle countless witch burnings in that region, with particular emphasis on the witches' meetings at the "Monte del Tonale", located at an altitude of 2000 m (ca. 6,000 ft). Field research has shown that plants of the nightshade family ("witching herbs") do not grow at this altitude; even the fly agaric mushroom is rarely found there. By contrast, pastures in the area abound with *Psilocybe semilanceata* during the fall. Given this historical context, it would seem likely that *Psilocybe semilanceata* played an important role as a psychotropic agent in the region (see Figure 58, Chapter 7.4).

In light of medieval accounts describing the practice of witchcraft, it is interesting to note that a subjective sensation of flying or levitation is among the commonly reported effects of psilocybin intoxication.

Berserk Rage of Nordic Warriors

In the course of the ideological power struggle between Christianity and the remnants of pagan religions that worshipped Nature, many sources of knowledge were lost. The aggressive repression and eradication of pre-Christian customs all but destroyed the continuity of Europe's original cultural heritage, along with much historic evidence documenting early cultural practices, including the usage of plants and mushrooms for the purpose of temporary alterations of consciousness.

Some authors went so far as to blame the fly agaric mushroom for proverbial fits of "berserk rage" attributed to Nordic warriors. Many accounts detailing this phenomenon allude to a "deception of the eyes" (i.e. visual hallucinations). After the Nordic legal system banished the practice of "going berserk", it disappeared quite suddenly during the 12th century. At about the same time, Saxo Grammaticus speculated that the Berserkers may have used magical potions.

It is just as plausible, however, to suggest that the hallucinogen of choice among early Nordic cultures was *Psilocybe semilanceata*, a mushroom species quite common in Norway. Neither *Amanita muscaria* nor *Psilocybe semilanceata* are generally known to cause states of intense rage. However, given the historic context, it is possible that, at the time, people had already begun to internalize negatively biased distortions and the demonization of psychoactive mushrooms and their effects, in order to justify the creation of new laws intended to destroy repulsive pagan customs such as the ritual use of mind-altering plants.

It is important to note the existence of ancient Northern European rock drawings that depict various mushroom themes, along with the discovery of bronze-age vessels decorated with mushroom-related artwork. The drawings often include renditions of zoomorphic entities as well as mushrooms. Significantly, they predate any reports and speculations about the Berserkers by over 2,000 years.

These ancient images suggest the evolution of early European mushroom cults - a cultural practice that most likely vanished during the early Iron Age, as did many other customs and social practices from that era. Still, the discovery of ancient Northern European mushroom cults is a powerful piece of evidence supporting the notion that psychoactive mushroom usage has been continuous throughout history.

In addition, a traditional Swedish custom has survived to the present day, revealing an early knowledge of a certain mushroom believed to evoke "visions of spirit entities". As part of summer solstice celebrations, a poisonous mushroom species ("Baran") was cast into the bonfires. Even though nothing is known about this fungus today, the ritual burning of a poisonous mushroom was intended to weaken the powers of goblins and other evil spirits. The mushrooms were viewed as symbolic incarnations of noxious spirits. The mushrooms' ritualistic destruction by fire thus destroyed the powers of evil and mischievous spirits. The assumption that some mushrooms are physical links to the intangible powers of the spirit world may have evolved from ancient fragments of knowledge about the psychoactivity of specific types of mushrooms.

There are a number of written reports about psychotropic mushrooms that date back to the late Middle Ages. While this collection of documents includes a variety of different sources from several countries, they provide remarkably similar descriptions of psychoactive mushrooms and the general nature of their effects.

Love Potions Brewed from *Bolond Gomba*

Clusius (1525-1609), for example, the great physician and botanist, discovered "bolond gomba" in Hungary. This mushroom was known under the German name "Narrenschwamm" ("fool's mushrooms"). It was used in rural areas, where it was processed into love potions by wise men or "javas asszony". At about the same time, this "fool's mushroom" was documented in Slovakia as well. In addition, the mushroom found its way into the verses of Polish poet Vaclav Potocki (1625-1699), who refers to its potential of "*causing foolishness much like opium does* ".

Similarly, in England, John Parkinson's "Theatricum Botanicum" (1640) includes details about a "*foolish mushroom*".

The Austrian colloquial expression "*He ate those madness-inducing mushrooms*" refers to states of mental confusion.

Historic source materials such as these are scarce and widely scattered. Undoubtedly, they refer to psychotropic mushrooms, but lack sufficient information to permit clear identification of a specific species. However, considering the habitats and occurrence of *Psilocybe semilanceata* and *Psilocybe bohemica*, these two species are among the most likely candidates (see page 16 ff.). It is remarkable that these historic portrayals revolve around just one aspect of the mushrooms' overall effects: the occasional semi-schizophrenic reaction which can at times be quite dramatic. None of these accounts reflect a distinct appreciation of mushrooms in the tradition of the Mexican Indians ("teonanacatl" = flesh of the Gods).

Between Reverence and Fear

By contrast, in Europe we find that the symptoms of mushroom intoxication have always been compared to symptoms of mental illness. Such cross-cultural differences in value judgments can be explained in terms of two concepts introduced by R.G. Wasson and his wife: *mycophilia* and *mycophobia*. This distinction subdivides cultures with different traditional attitudes towards mushrooms into two groups. For instance, an entrenched dislike for mushrooms (mycophobia) in Britain indicates traditional beliefs vastly different from those found in Slavic countries, where mushrooms are generally cherished (mycophilia). The origins and evolution of such diverging attitudes remain lost in the shadows of history.

The development of early cultural taboos and prohibitions against psychotropic mushrooms may be the root cause of enduring mycophobic behavior. On the other hand, it is possible that, thousands of years ago, the process of harvesting mushrooms as a food source caused alarming clusters of regionally isolated cases of fatal mushroom poisonings. Such experiences may well have seeded a potent and lasting aversion towards an entire country's mycoflora.

Similarly, the mycophilia typical of ancient Mexican cultures goes hand in hand with a general social acceptance of the effects of *Psilocybe* mushrooms and their established ritual usages. Among Mexican Indian tribes, the effects of psilocybin have never been causally linked to any type of known mental illness. It is interesting to note that the Indians of Mexico were the only Indians in the Americas who also harvested a large number of mushroom species for food.

Unfortunately, our current socio-political climate is - strongly biased against newly discovered hallucinogens, which are often defined in terms of negatively loaded labels. Even worse, such prejudicial thinking distorts an objective, scientifically neutral approach to the study of these substances. The label "fool's mushroom" first appeared during the 1930s, along with "Mexican mushroom of insanity". In the 1950s, the Central American mushroom cults were discovered and the mushrooms themselves were renamed "Mexican magic mushrooms", in recognition of their psychotropic effects and to emphasize the significance of the mushrooms' early integration into the social fabric of the cultures that cherished them.

Later on, the relatively neutral label "hallucinogenic mushroom" came into use in the mycological literature. Other designations that gained and lost popularity over time include the somewhat derogatory term "intoxicating mushrooms" and the essentially meaningless "drug mushrooms".

Scientifically Unbiased Hallucinations?

Following his experiments with magic mushrooms in Mexico during the summer of 1960, T. Leary returned to Harvard University and began to study psilocybin as a variable in the administration of standard psychological test batteries. His initial focus was diluted when he continued to expand his experiments to include increasingly broader settings and applications. In reaction to Leary's markedly unorthodox approach, the American press began to portray psilocybin mushrooms in terms of slanderous terminology that far exceeded the negative connotations of labels such as "fool's mushrooms". Descriptions of the mushrooms' effects included claims that users experienced "death-like states".

Proponents of psilocybin research were accused of denying that the alkaloid caused "semipermanent brain damage". This pseudo-scientific jumble of meaningless jargon was symptomatic of the sharply escalating controversy surrounding hallucinogenic substances. Increasingly, news reports on psilocybin were eclipsed by massive amounts of publicity about LSD - the most potent hallucinogen ever discovered. The subsequent frenzy of legislative attempts to control LSD resulted in ever tighter restrictions on the scientific study of not only LSD, but psilocybin as well. Mind-altering substances were no longer thought of in terms of their specific effects and properties, but rather were lumped together into a single group of dangerous chemicals. As antidrug hysteria continued to intensify, scientific and pharmacological distinctions became all but irrelevant: hallucinogens were no longer viewed as different from other classes of dangerous and physically addictive drugs, such as heroin or the opiates. This demonization of hallucinogens was successful in spite of massive research efforts that began when Sandoz Pharmaceuticals decided to distribute psilocybin to qualified scientists for experimental and psychotherapeutic purposes. By employing the method for synthesis of psilocybin developed by A. Hofmann, Sandoz Pharmaceuticals manufactured about 2 kg (ca. 4.4 lbs) of pure psilocybin for scientific research purposes.

The results of pharmacological testing soon revealed psilocybin as an alkaloid that was perfectly safe for human subjects under controlled experimental conditions. Despite this evidence, the anti-drug legislative framework of the mid-1960s firmly established an "official mycophobia", a misguided, yet entrenched policy that still prevails today and effectively prevents the scientific investigation of promising potential applications for psilocybin and other alkaloids. At the same time, mycological and biochemical research studies have shown that psilocybin-containing mushrooms thrive all over the world and can be found on all continents. These mushrooms are no different from any other mycoflora and must not be excluded from scientific investigation because of their alkaloid content.

In addition to overall variations in value systems across cultures, individuals tend to develop their own personal attitudes towards mushrooms in general. Oftentimes, the evolution of specific opinions about mushrooms can be traced back to childhood events, even though such early experiences seldom account for the development of prevailing biases and value systems later in life.

I recall an incident from my own childhood, which occurred when I was about five years old. I was playing in a grassy meadow, when a girl pointed to a brown mushroom and earnestly explained that it was inedible and poisonous. While I have never forgotten this encounter, I did grow up to become a devoted mushroom enthusiast. On the other hand, a different childhood event has left me with the vivid memory of discovering a landfill virtually covered with vast numbers of gilled bluing mushrooms and the sense of awe I experienced contemplating this sight. In general, the unusual characteristics of these mushrooms are most likely responsible for strong impressions formed early in life, which then may develop into various attitudes or beliefs later on.

An enduring personal interest in psychotropic mushroom species can serve to amplify or diminish mycophobic as well as mycophilic dispositions, depending on the influence of other factors. After all, judgments about the benefit or folly of deliberately altering one's state of consciousness are also colored by individual preferences, biases and opinions.

The following chapters are meant to illustrate this diversity of attitudes towards psychotropic mushrooms. Descriptions of planned and involuntary experiments with specific mushroom species offer convincing evidence that the effects of psychoactive mushrooms are open to many possible interpretations.

CHAPTER 3
The Current State of Knowledge About European Species

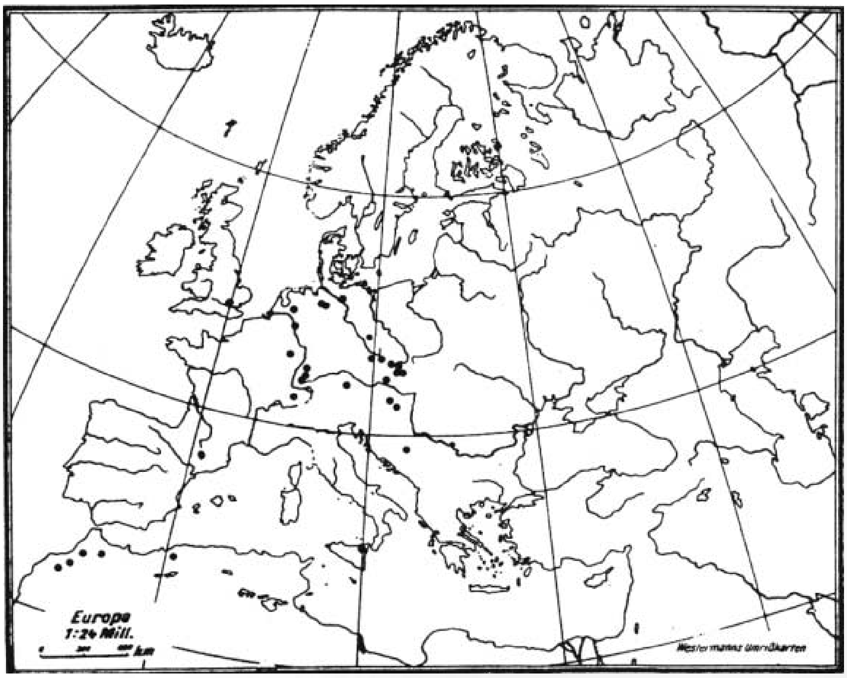

Figure 7 - Distribution pattern of ***Psilocybe cyanescens*** across Europe and North Africa (according to Krieglsteiner). Black dots indicate approximate locations where ***Psilocybe cyanescens*** was found.

Mr. E Branl, on a poisonous Species of Agaric

To the Editors of the "Medical and Physical Journal".

Gentlemen,

IF the following account of the deleterious effects of a very common species of agaric, not hitherto generally suspected to be *poisonous*, appears to you likely to prove *useful* or interesting to the public, you will oblige me by its insertion; should its length be any obstacle to this, I beg you will omit whatever you may think superfluous.

I remain,
Gentlemen,
Yours, most obediently,
EVERARD BRANDE
No.10, Arlington-Street,
Nov. 16th, 1799.

J. S. gathered early in the morning of. the third of October, in the Green Park, what he Supposed to be small mushrooms; there he stewed with the common additions in a tinned iron saucepan.* The whole did not exceed a tea saucerful, which he and four of his children ate the first thing, about eight o'clock in the morning, as they frequently had done without any bad consequence; they afterwards took their usual breakfast of tea, &c. which was finished about nine, when Edward, one of the children, (eight years old,) who had eaten a large proportion of the mushrooms, as they thought them, was attacked with fits of immoderate laughter, nor could the threats of his father-or mother restrain him. To this succeeded vertigo, and a great 'degree of stupor, from which he was roused by being called or shaken, but immediately relapsed. The pupils of his eyes were, at times, dilated to nearly, the circumference of the cornea, *and* scarcely contracted at the approach of a strong light; his breathing was quick, his pulse very variable, at times imperceptible, at others too frequent and small to be counted; latterly, very languid; his feet were cold, livid, and contracted, he sometimes pressed his hands on different parts of his abdomen, as if in pain, but when roused and interrogated as to it, he answered indifferently. yes, or no, as he did to every other question, evidently without any relation to what was asked. About the same time the father, aged forty, was attacked with vertigo, and complained that every thing appeared black, then wholly.

*This accuracy may seem trivial, but I have met with people who supported the following symptoms might have arisen from the use of a copper vessel.

Figure 8 - Reproduction of a report from the mycological literature (1799) describing a case of ***Psilocybe semilanceata*** intoxication.

3.1 - *Psilocybe semilanceata*: The Classic Species Among European Psychotropic Mushrooms

Listen Well to this Frightful Story from St. James's Green Park....

About 200 years ago, E. Brande published an account about a remarkable case of mushroom intoxication in London. On October 3, 1799 an impoverished family picked some mushrooms in St. James's Green Park and prepared them for a meal (see Figure 8, p. 15).

Shortly after eating the mushrooms, the father and his four children developed symptoms of intoxication, such as markedly dilated pupils, spontaneous laughter and delirium. The progression of symptoms was experienced as wave-like, with cycles of increasing and fading intensity. In addition, the father's visual perception was affected so that everything around him appeared to be black - a frightening experience he believed to presage his impending death.

Even though two family members (ages 12 and 18) consumed only small amounts of the cooked mushrooms, the ensuing symptoms of intoxication were no different from those observed in family members who had eaten comparatively larger portions. After several hours, the psychic and perceptual disturbances subsided and finally disappeared, without any lingering side effects. Attempts to treat acute symptoms included administration of emetics and fortifying tonics. In the end, these potions were heralded as the crucial treatment that "cured" the family.

For the most part it is extremely difficult, if not impossible, to assemble complete and accurate details on many aspects of magic mushroom history from source materials available today. Thus, it is an instance of rare good fortune and a boon to mushroom historians that E. Brande's description of a typical psilocybin syndrome was augmented by J. Sowerby, author of "Coloured Figures of English Fungi or Mushrooms" (London, 1803). Sowerby's book included a rendition and description of the mushroom species responsible for the poisoning case described by Brande (see p. 17). Within the context of Sowerby's book, only the variety of mushrooms distinguished by their cone-shaped caps were believed to cause intoxication. Figure 9 shows a typical rendition of *Psilocybe semilanceata*. This mushroom species was known to Sowerby's contemporaries as "*Agaricus glutinosus* Curtis" and its descriptions are fully compatible with current knowledge about *Psilocybe semilanceata*.

A few years later, renowned Swedish mycologist E. Fries referred to "*Agaricus semilanceatus*" in his book entitled "Observationes Mycologicae" (1818). Later on, the same mushroom also appeared under the names *Coprinarius semilanceatus* Fr. or *Panaeolus semilanceatus* (Fr.) Lge. Not until 1870 did Kummer and Quelet classify this mushroom as a member of the genus *Psilocybe*. Consequently, two valid designations may be found in the literature:

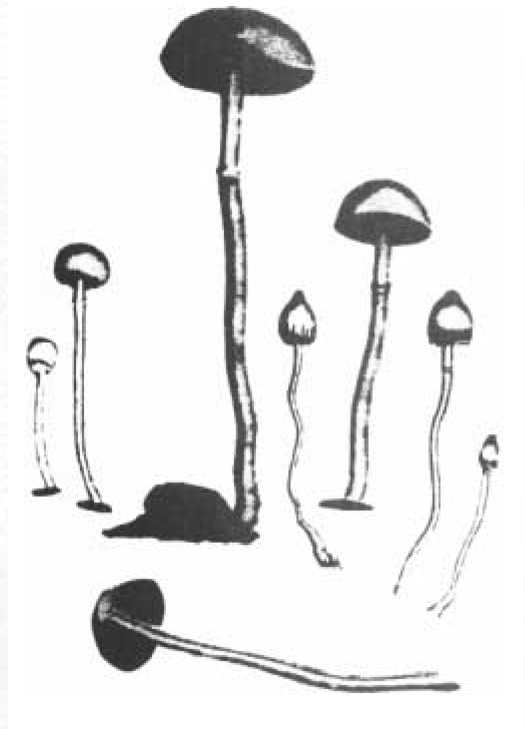
- *Psilocybe semilanceata* (Fr.) Kumm.
or
- *Psilocybe semilanceata* (Fr.) Quel.

Around 1900, M. C. Cooke reported two or three new instances of accidental mushroom intoxication involving children in England. Interestingly, Cooke noted that symptoms were caused only by a variety of mushroom known to turn blue (var. *caerulescens*). He was the first mycologist to wonder if a bluing variety of this species was poisonous, or if the bluish color was induced by external factors, causing changes in the mushroom's chemical composition so as to render them poisonous.

Early Descriptions

A close relative of Mexico's psychoactive species, *Psilocybe semilanceata* is a mushroom whose physical appearance resembles *Psilocybe semperviva* Heim & Cailleux and *Psilocybe mexicana* Heim. Like *Psilocybe semilanceata*, these Mexican species thrive in meadows and pastures. Another common trait among these species is the rather subdued and subtle quality of their bluing reaction. Recognition of these similarities with

Mexican species sparked the curiosity of scientists who wanted to learn more about Europe's *Psilocybe* species. A research team that included A. Hofmann and R. Heim began to study samples of *Psilocybe semilanceata*, in collaboration with C. Furrer, a mycologist who examined fruiting bodies collected in Switzerland and France. By 1963, paper chromatography testing had yielded data of historic significance. For the first time, scientists had confirmed the presence of 0.25% psilocybin in dried samples of *Psilocybe semilanceata*. Publication of the results represented an extraordinary achievement, because psilocybin had never before been detected in a European mushroom species. Previously, the alkaloid had been found only in *Psilocybe* species native to Mexico, Asia and North America.



Stalks generally single, sometimes clustered, from two to four inches in height, the thickness of a goose quill, thread shaped whitish almost solid, the tube being very small, glutinous; ring, a little below the cap, scarce perceptible.

"Cap, from one to two inches in breadth, of a brown color; in the full grown ones hemispherical, always convex, and more or lets glutinous; wet with rain, it becomes browner and transparent, so that it sometimes appears striated."

"Gills numerous, single, of a brownish purple color, clouded; whole ones about twenty, horizontal, three shorter ones placed between them; they throw out a powder of a brownish purple color."
With respect to the use of it, he only says, "There is nothing acrimonious or disagreeable in its taste, yet its appearance will not recommend it to the lovers of mushrooms."

Figure 9 - Drawing and description of ***Psilocybe semilanceata*** by J. Sowerby (London, 1803).

1733. A. semilanceatus Fries (Observ. II. pag. 178)

Synon.: Agaricus semiglobatus Sowerby (Engl. Fungi taf. 240. fig. 1-3). Hut etwas hautig, spitz kegelfdrmig, fast zugespitzt, 1½ Cent. breit, ½ Cent. hock, feucht klebrig, fein streifig, gelb oder grunlich, zah, mit Anfangs umgeknicktem Rande und leicht trennbarer Oberhaut. Stiel zah, gebogen, 11 Cent. hock, kahl, blass. Lamellen angeheftet, aufsteigend, purpur-schwarz. Sporen ellptisch, hellbraun, 9 -16 µ lang, 4 - 9 µ dick.

Ax **Wegen, auf Grasphitzen, besonders wo Mist gelegen hat.**

spitzkegeliger Kahlkopf (Psilocybe semilanceata). Kegel-glockenformig mit papilenertiger spitze Hut-o, 5-1 cm breit, bis 2 cm hock, lehmfarben mit olivgrunem Stich, klebrig. Lamellen breit, oliv-lehmfarben, spater purpurbraun.
Stiel schlank, glanzend. - Gedungte Wiesen, Wegrander. Stellenweise. Wertlos.

Figure 10 Two descriptions of ***Psilocybe semilanceata*** from the German-language literature. The first description (top) was written over a hundred years ago, while the second one (bottom) dates to 1962. Significantly, the more recent entry classifies the species as "essentially worthless". Also see Figure 11.

While *Psilocybe semilanceata* was not recognized as an important psychoactive species until the 1960s, descriptions of the species were included in many standard German language mycology reference books published before 1963. Figure 10 shows examples of two such descriptions, one of them dated 1962 and the second one written about 60 years earlier. Note that the 1962 version designates *Psilocybe semilanceata* as a "worthless" species - a rather incongruous conclusion likely to amuse today's readers. On the other hand, accounts of and knowledge about cases of mushroom intoxication in England did not find their way into

Germany's mycological literature. A few authors, such as Michael & Schulz (1927) and A. Ricken (1915) see Figures 11 and 12, pp. 19-20) contributed excellent and valuable descriptions of *Psilocybe semilanceata*, but these are the exceptions, rather than the rule. A description of *Psilocybe semilanceata* from 1977 reflects less emphasis on details, and a rather cursory approach to differentiation of the species, except for additional data on the mushroom's microscopic characteristics (see Figure 13).

In addition, a German aquarelle painting from 1927 of five fruiting bodies depicts the mushroom's habitus in remarkably realistic detail (see Figure 1, p. 4).

In 1967 and 1969 *Psilocybe semilanceata* samples from Scotland and England were found to contain psilocybin as well. Later on (1977), Michaelis reported discovering the alkaloid in samples collected in Germany (see Figure 14).

The Popularity of *Psilocybe semilanceata*

Since the late 1970s, investigators in several countries have been using of state-of-theart methodology (High Performance Liquid Chromatography) to test samples and quantify their alkaloid content. The following sections include more detailed reviews of these tests and their results.

Psilocybe semilanceata has clearly established itself as the psychotropic mushroom species in Europe. The species thrives throughout the European continent, where it has sparked extensive research efforts. In terms of usage, *Psilocybe semilanceata* is Europe's most popular psychoactive species. In his 1983 monograph, Guzman suggests that *Psilocybe semilanceata* may well be the most common psychoactive *Psilocybe* mushroom in the world. Even though the species is known to flourish in Europe, North America, Australia and Asia, the mycofloras of many countries have not yet been studied or documented. Thus, we cannot yet evaluate the prevalence of *Psilocybe semilanceata* on a global scale.

In Europe, however, discoveries of *Psilocybe semilanceata* have been reported from the following countries: Finland, Norway, Sweden, Denmark, Germany, Switzerland, Austria, The Netherlands, Belgium, France, Russia, Poland, the former Czechoslovakia, Hungary, Romania, Scotland, England, Wales, Italy and Spain.

189. Psilocybe semilanceata Fr. [Worthless]

The cap is uniformly conic to bell-shaped, with a pointy or obtuse center forming an almost wart-like protrusion; initially, caps are often taller than they are wide, margins are bent and curved inward; later on, width of cap is 1.5-4 cm. Hygrophanous; coloration is a dirtyish olive-brown when wet, with translucent striate margins; at the center, coloration is ocher or greenish-yellow against an overall shade of smudgy pale yellow and oftentimes some greenish stains; only the margins are banded by a darkcolored, watery stripe around the edge. No stripes or banding evident when mushrooms are completely dried. Lacking a veil, caps are thin-fleshed, bald, with an easily separable pellicle that remains gelatinous-sticky for a long time, turning shiny when dry.

Gills are olive brown to blackish purple brown in color, with the edges often remaining white, gill spacing is quite crowded; gill attachment is either roughly linear or mostly adnexed; up to 3.5 mm wide; attached at the stem only, fully detached later on.

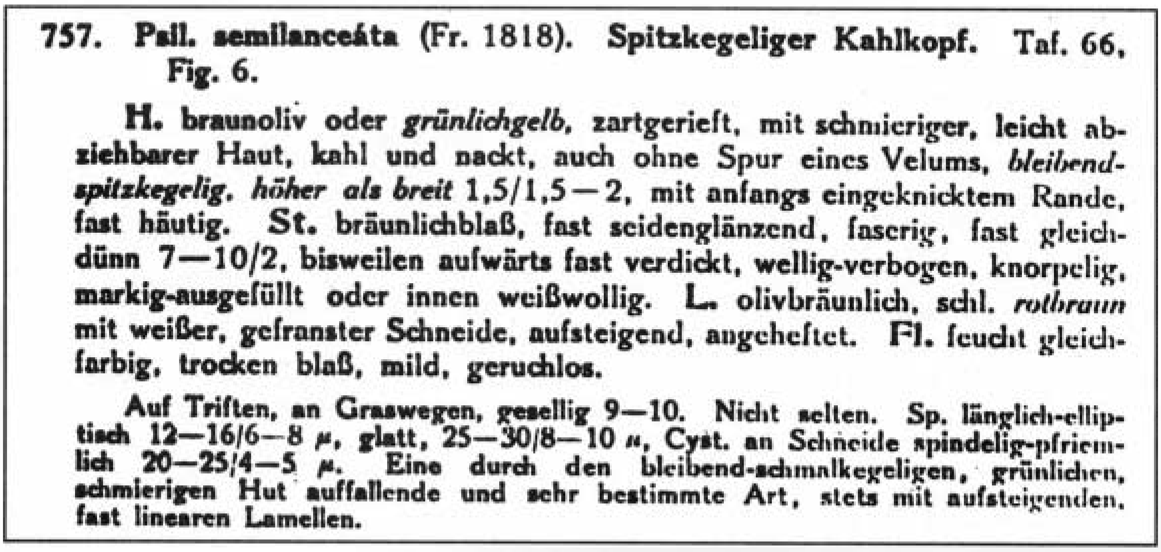
Spores are elongated to ellipitical in shape, smooth and large, measuring 12-16 µ by 6-8 µ. Color of spore dust is blackish purple brown.

Stem is very slender, almost uniformly thin and always twisted, 6-12 cm long and 1.25-2 mm thick, yellowish or whitish in color; areas subjected to pressure develop bluish-green stains. Stems are silky smooth and roughly at the center, cortinate fibrils appear like remnants of a veil, which is brittle and lined with a white fibrous cord of wool-like texture.

When dry, the flesh of the cap is colored pale yellow, while the stem's flesh is ocher brown in color, especially towards the bottom. It is odorless and its flavor is mild. The mushroom grows from August to October, frequently in gregarious clusters, and can be found in pastures and along roadways, growing on dung that has undergone complete decomposition. It is not a particularly rare species.

Figure 11 - (above) This excellent description of ***Psilocybe semilanceata*** by Michael & Schulz (1927) is shown here as originally published in German, with an English translation.

Unfortunately, there are no comprehensive maps detailing the species's distribution pattern. Traditionally, mycologists have often neglected relatively tiny species, such as *Psilocybe semilanceata*, that tend to share their habitats with other, more prominent species. The sarcastic phrase "*The mushrooms occur in abundance wherever mycologists abound*" is particularly pertinent in reference to the *Psilocybe* species. Prior to the discovery of psilocybin, the *Psilocybe* genus languished in the literature, shrouded in obscurity. To this day, few Mycologists specialize in the study of *Psilocybes*, despite the fact that *Psilocybe semilanceata* is the most common and conspicuous species among the *Psilocybes*. Also, mushroom lovers whose interests are not purely scientific (see Chapter 7.4) do not usually preserve their knowledge for posterity in the form of distribution maps. However, there is one map from 1986, which shows the distribution pattern of *Psilocybe semilanceata* across Germany (see Figure 20, p. 28).

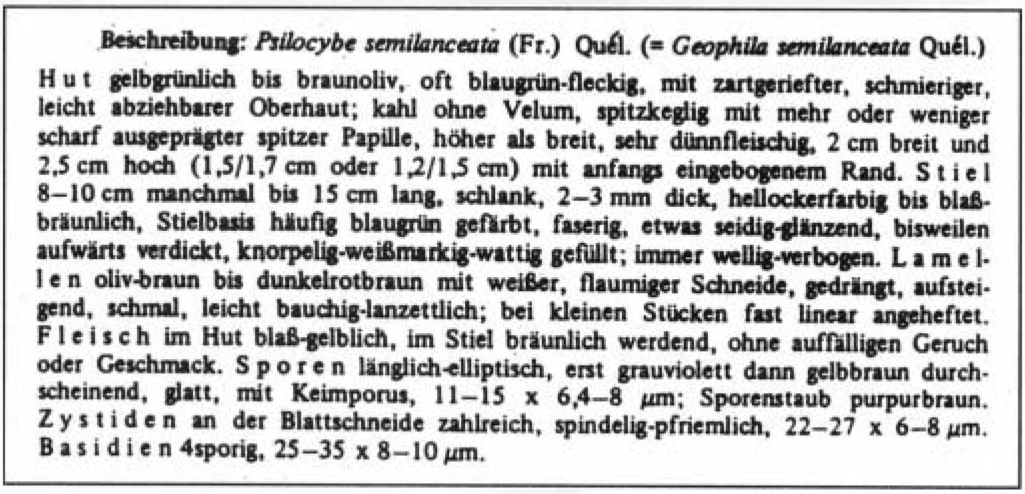


757. Psil. semilanceáta (Fr. 1818). **Spitzkegeliger Kahlkopf.** Taf. 66, Fig. 6.

H. braunoliv oder *grünlichgelb*, zartgerieft, mit schmieriger, leicht abziehbarer Haut, kahl und nackt, auch ohne Spur eines Velums, *bleibend-spitzkegelig, höher als breit* 1,5/1,5—2, mit anfangs eingeknicktem Rande, fast häutig. **St.** bräunlichblaß, fast seidenglänzend, faserig, fast gleichdünn 7—10/2, bisweilen aufwärts fast verdickt, wellig-verbogen, knorpelig, markig-ausgefüllt oder innen weißwollig. **L.** olivbräunlich, schl. *rotbraun* mit weißer, gefranster Schneide, aufsteigend, angeheftet. **Fl.** feucht gleichfarbig, trocken blaß, mild, geruchlos.

Auf Triften, an Graswegen, gesellig 9—10. Nicht selten. Sp. länglich-elliptisch 12—16/6—8 μ, glatt, 25—30/8—10 μ, Cyst. an Schneide spindelig-pfriemlich 20—25/4—5 μ. Eine durch den bleibend-schmalkegeligen, grünlichen, schmierigen Hut auffallende und sehr bestimmte Art, stets mit aufsteigenden, fast linearen Lamellen.

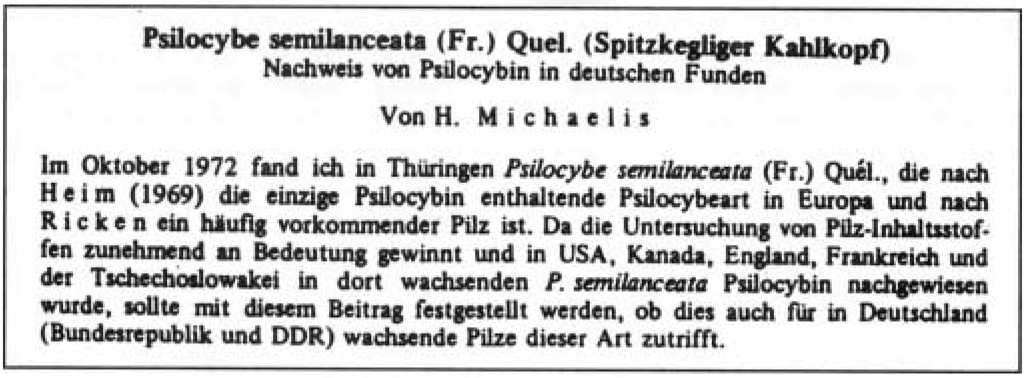
Figure 12 - A. Ricken's description of ***Psilocybe semilanceata*** from 1915.



Beschreibung: *Psilocybe semilanceata* (Fr.) Quél. (= *Geophila semilanceata* Quél.)

Hut gelbgrünlich bis braunoliv, oft blaugrün-fleckig, mit zartgeriefter, schmieriger, leicht abziehbarer Oberhaut; kahl ohne Velum, spitzkeglig mit mehr oder weniger scharf ausgeprägter spitzer Papille, höher als breit, sehr dünnfleischig, 2 cm breit und 2,5 cm hoch (1,5/1,7 cm oder 1,2/1,5 cm) mit anfangs eingebogenem Rand. Stiel 8–10 cm manchmal bis 15 cm lang, schlank, 2–3 mm dick, hellockerfarbig bis blaßbräunlich, Stielbasis häufig blaugrün gefärbt, faserig, etwas seidig-glänzend, bisweilen aufwärts verdickt, knorpelig-weißmarkig-wattig gefüllt; immer wellig-verbogen. Lamellen oliv-braun bis dunkelrotbraun mit weißer, flaumiger Schneide, gedrängt, aufsteigend, schmal, leicht bauchig-lanzettlich; bei kleinen Stücken fast linear angeheftet. Fleisch im Hut blaß-gelblich, im Stiel bräunlich werdend, ohne auffälligen Geruch oder Geschmack. Sporen länglich-elliptisch, erst grauviolett dann gelbbraun durchscheinend, glatt, mit Keimporus, 11–15 x 6,4–8 μm; Sporenstaub purpurbraun. Zystiden an der Blattschneide zahlreich, spindelig-pfriemlich, 22–27 x 6–8 μm. Basidien 4sporig, 25–35 x 8–10 μm.

Figure 13 - Description of ***Psilocybe semilanceata*** by H. Michaelis (1977).



Psilocybe semilanceata (Fr.) Quel. (Spitzkegliger Kahlkopf)
Nachweis von Psilocybin in deutschen Funden

Von H. Michaelis

Im Oktober 1972 fand ich in Thüringen *Psilocybe semilanceata* (Fr.) Quél., die nach Heim (1969) die einzige Psilocybin enthaltende Psilocybeart in Europa und nach Ricken ein häufig vorkommender Pilz ist. Da die Untersuchung von Pilz-Inhaltsstoffen zunehmend an Bedeutung gewinnt und in USA, Kanada, England, Frankreich und der Tschechoslowakei in dort wachsenden *P. semilanceata* Psilocybin nachgewiesen wurde, sollte mit diesem Beitrag festgestellt werden, ob dies auch für in Deutschland (Bundesrepublik und DDR) wachsende Pilze dieser Art zutrifft.

Figure 14 - Excerpt from the first article reporting the discovery of psilocybin in ***Psilocybe semilanceata*** samples from Germany Michaelis (1977).

Almost no published information is available about locations where *Psilocybe* species have been found in eastern Germany. During my own field trips, I have discovered *Psilocybe semilanceata* specimens in various locations, such as near my hometown of Mansfeld in the Vorharz Mountains, in the marshlands of Duben as well as in other eastern German marshland areas. In addition, friends who are also mycologists have told me about finding the mushrooms in other parts of the country. A book published in 1952 is among the rare sources that includes details about specimens discovered in the southeastern state of Saxony (see Figure 16, p. 23).

The *Psilocybe* species grow most abundantly on wet pastures surrounded by forest areas. In my experience, *Psilocybe semilanceata* grows in most of Germany's forestlands. The species fruits during the fall, from late September through October. It favors acidic soil and grassy terrain alongside trails or around the edges of forest lands. Specimens are generally clustered in small groups of 30 mushrooms or less. Deer droppings or other animal feces are usually present at those locations, even though the mushrooms never grow directly on top of dung. Occasionally, extremely stunted specimens may be found in the mountains by the side of the road.

The soil below older cow pastures provides an excellent medium for extensive mycelial growth. In some locations, large areas yield an abundance of fruiting bodies, mirroring the extent of mycelial saturation in the soil. Given adequate moisture, maximum yields can be expected, if the pasture was grazed at least once during the weeks before fruiting season. However, the mushrooms also thrive under similar conditions on horse and sheep pastures. Such grassy areas inside forests are usually grazing areas for deer, who provide the soil with additional fertilization. *However, Psilocybe semilanceata does not grow in locations where artificial fertilizer has been used*. Such pastures are often flanked by creeks or swamp lands, which saturate the soil with water. During the summertime, the warm climate in these wet areas provides an excellent environment for optimal mycelial growth. In Germany, the mushroom's habitat ranges from the coastal areas to mountainous regions, where the species has been found at altitudes of up to 1,720 m (5,160 ft) above sea level (MTB-8443, 1985). In the former Czechoslovakia, samples have been collected at altitudes ranging from 330 to 1,000 m (1,000 - 3,000 ft), with one location at 1,400 m (4,200 ft) above sea level. According to these distribution patterns, the species does not appear to favor a specific altitude. As of 1986, 44 locations in the former Czechoslovakia had been logged, yielding a total of 54 samples. In contrast to other mushroom species, such as the cultivated commercial white mushrooms (*Agaricus bisporis*), *Psilocybe semilanceata* will fruit in a comparatively much wider range of temperatures.

While *Psilocybe semilanceata* is common throughout Germany, the species does not appear to favor specific areas where it occurs in marked abundance or density. One obvious limitation on the growth of the species is the limited presence of fertilizer in areas that would otherwise be excellent locations for the mushroom to thrive in. Most likely that is why the species has not expanded into new habitats in Germany over the last few decades. Descriptions of frequency of occurrence in the older literature are comparable to contemporary observations.

On occasion, however, *Psilocybe semilanceata* can produce a huge number of fruiting bodies at certain locations where conditions for growth are excellent.

Between a Creek and a Marshlands Pond… 8½ Inches Tall!

At this point, I would like to provide some more details about two marshlands locations, where we have conducted mycological field research over the course of several years.

At the first location, the fruiting bodies grew in a shallow grass valley among very tall grass on slightly acidic soil. This grassy area was a forest clearing between a creek and a marshlands pond. In areas exposed to direct sunlight, temperatures were significantly higher than they were in surrounding areas, a phenomenon that persisted during the fall season. Deer droppings contributed to frequent fertilization of the area. The fruiting bodies from the first batch of mushrooms found in this location had stems of up to 8½ in. [!] (21.5 cm) tall, due to very tall grass in the area. The caps of the mushrooms were so tiny, that clear identification of the species as *Psilocybe semilanceata* was not immediately possible. Even though a bluing reaction was present, chromatography testing was needed to confirm the species. Subsequent discoveries, however, yielded samples that could be identified on the spot based on their morphological characteristics. We were able to collect 30 to 60 specimens at this location every fall for three consecutive years. Unfortunately, the location was destroyed soon afterwards, due to man-made modifications to the marshlands and construction of an access road.

During the same year, we discovered a second location within about half a mile of the first one. The area was very large, a former cow pasture which had been grazed regularly. It was located next to a creek that saturated the soil completely. Today, sheep occasionally graze the area and deer droppings are commonly found in the grass. Here, *Psilocybe semilanceata* fruits in abundance. Each fall season, the pasture is covered with hundreds of fruiting bodies (see Figure 15, p. 23).

For three years, we returned to the area three times each fall, and harvested a total of 2,800 mushrooms (ca. 140 g or 5 oz dry weight) at the location. While some of the fruiting bodies could be spotted easily on the grassy soil (see Figure 17) the vast majority of the specimens were usually concealed inside clumps of grass (see Figure 18).

When the weather is dry, *Psilocybe semilanceata* is an easily recognizable species. The fruiting bodies are extremely hygrophanous, which is why the color of the caps changes to a dark olive black-brown when the mushrooms are wet. Only a close inspection of the gills and the crooked stems enabled us to differentiate the wet mushrooms from the *Panaeolus* species (see Chapter 3.3). Like many other psychotropic mushroom species, a crucial characteristic of *Psilocybe semilanceata* is the blue discoloration of parts of the cap and the lower half of the stem, While the degree of discoloration is relatively minor, it is particularly noticeable when the mushrooms are wet. Fruiting bodies that are old and wet may spontaneously develop transparent, blue stains across their caps. On the other hand, discoloration of the stems does not set in until the fruiting bodies have been separated from the mycelia for about 30 to 60 minutes. Even in areas of abundant harvests, I have always found mushrooms with bluish-green discoloration's alongside others that lacked this characteristic. During the drying process, the blue coloration is preserved, even though some fading may occur.

The historic descriptions of *Psilocybe semilanceata* cited above are so detailed that I cannot add any of better quality. In spite of many opinions in the literature to the contrary, there is a noticeable odor that emanates from damp fruiting bodies that have been opened. This odor is similar to, but weaker than the one associated with *Psilocybe bohemica*, which is often described as reminiscent of radishes or poppies, but as generally not unpleasant (also see Chapter 3.2).

In addition, the mushrooms have another special attribute that rarely occurs in other species. Under the light of a quartz lamp, *Psilocybe semilanceata* specimens turn fluorescent. The substance responsible for this phenomenon, however, has not yet been identified.

Accounts of Impressive Experiences

Psilocybe semilanceata is quite likely the most potently psychoactive mushroom among the European species. The impressive nature and rapid onset of the effects are reflected in the description of an intoxication from England cited above. These elements are also part of the following account, which details a mycologist's first self-experiment:

> *After ingesting 1.3 g (less than one-sixteenth of an ounce) of dried and pulverized mushrooms (30 mushrooms total) in water on an empty stomach, 20 minutes passed before the sudden onset of hallucinatory effects, including a heavy flow of tears. The apparitions are best described as a conjunction of visions and thoughts - later on I discovered the term "visualization" in the literature. I had an extremely uncomfortable experience of a daydream-like flight, where my arm had been seized by a witch... There were three of us flying somewhere, sometime. After that, all objects in my immediate surroundings appeared pale and bleached. With my eyes closed I "saw" abstract ornaments with no distinct luminescence or emotional impact. During this time, free-floating dysphoria developed, along with guilt-ridden ruminations. After five hours, the effects ended suddenly, followed by the gradual onset of a mild headache, while no other side effects were noted.*

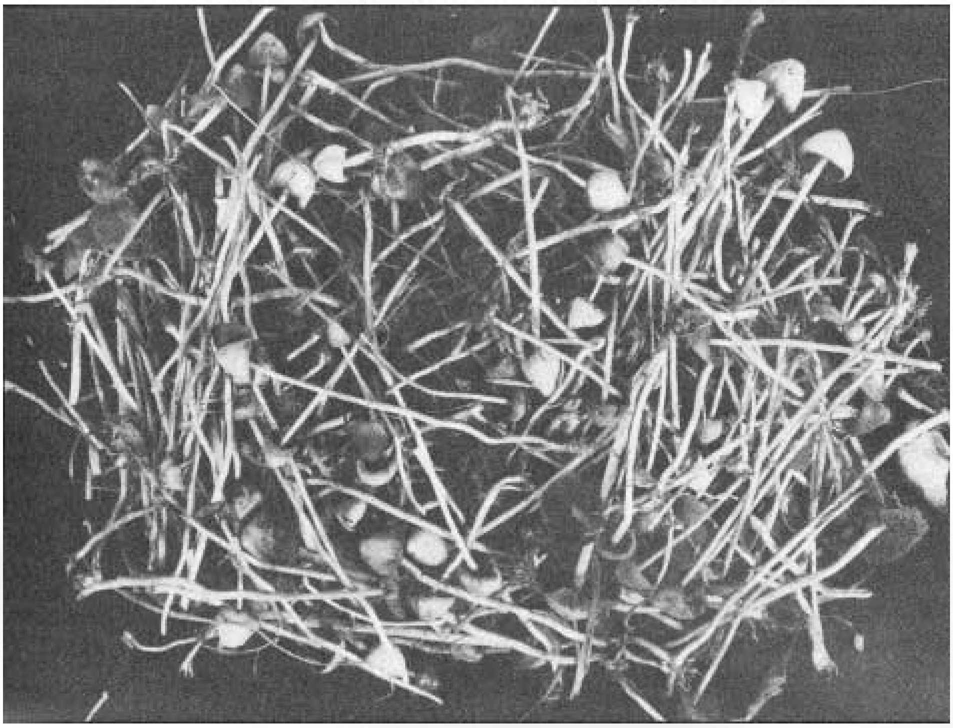


Figure 15 - Harvest of ***Psilocybe semilanceata*** mushrooms from a single location (Eastern German marshlands, 1989).

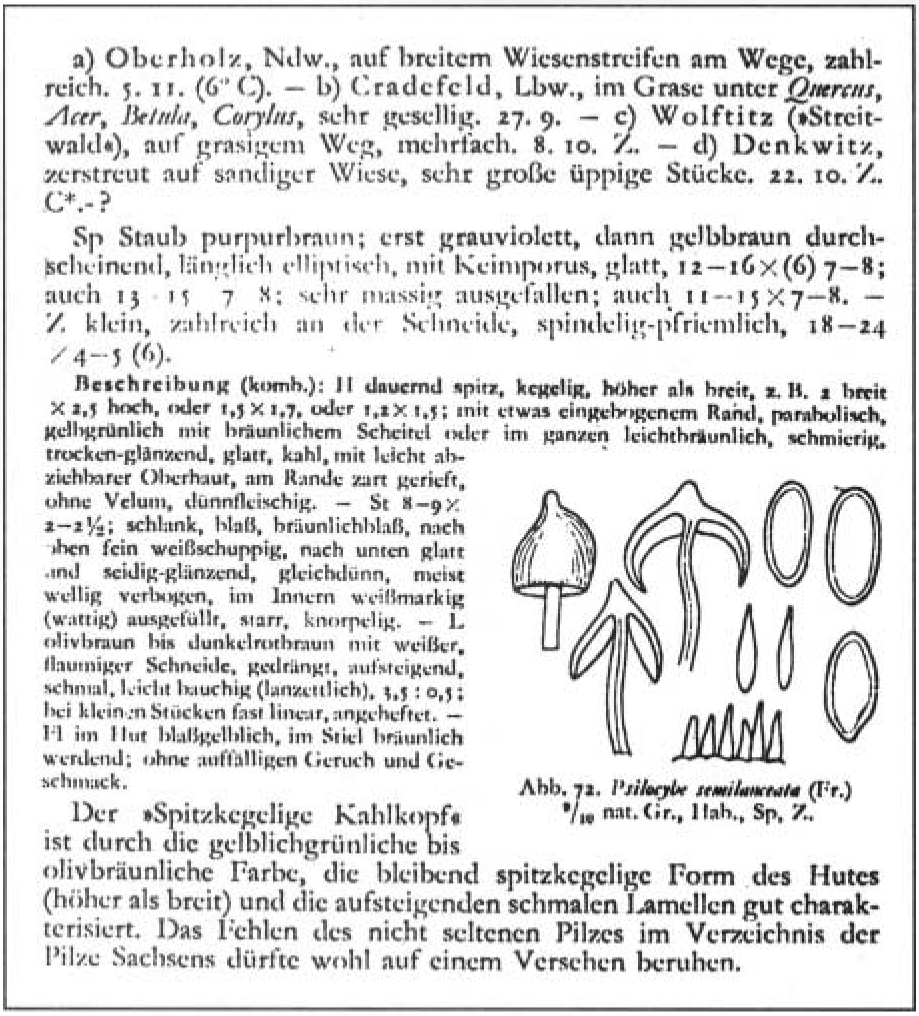

a) Oberholz, Ndw., auf breitem Wiesenstreifen am Wege, zahlreich. 5. 11. (6° C). – b) Gradefeld, Lbw., im Grase unter *Quercus*, *Acer*, *Betula*, *Corylus*, sehr gesellig. 27. 9. – c) Wolftitz (»Streitwald«), auf grasigem Weg, mehrfach. 8. 10. Z. – d) Denkwitz, zerstreut auf sandiger Wiese, sehr große üppige Stücke. 22. 10. Z. C*.-?

Sp Staub purpurbraun; erst grauviolett, dann gelbbraun durchscheinend, länglich elliptisch, mit Keimporus, glatt, 12–16×(6) 7–8; auch 13–15×7–8; sehr massig ausgefallen; auch 11–15×7–8. – Z. klein, zahlreich an der Schneide, spindelig-pfriemlich, 18–24×4–5 (6).

Beschreibung (komb.): H dauernd spitz, kegelig, höher als breit, z. B. 2 breit × 2,5 hoch, oder 1,5×1,7, oder 1,2×1,5; mit etwas eingebogenem Rand, parabolisch, gelbgrünlich mit bräunlichem Scheitel oder im ganzen leichtbräunlich, schmierig, trocken-glänzend, glatt, kahl, mit leicht abziehbarer Oberhaut, am Rande zart gerieft, ohne Velum, dünnfleischig. – St 8–9× 2–2½; schlank, blaß, bräunlichblaß, nach oben fein weißschuppig, nach unten glatt und seidig-glänzend, gleichdünn, meist wellig verbogen, im Innern weißmarkig (wattig) ausgefüllt, starr, knorpelig. – L olivbraun bis dunkelrotbraun mit weißer, flaumiger Schneide, gedrängt, aufsteigend, schmal, leicht bauchig (lanzettlich), 3,5 : 0,5; bei kleinen Stücken fast linear, angeheftet. – Fl im Hut blaßgelblich, im Stiel bräunlich werdend; ohne auffälligen Geruch und Geschmack.

Abb. 72. *Psilocybe semilanceata* (Fr.) 8/10 nat. Gr., Hab., Sp, Z.

Der »Spitzkegelige Kahlkopf« ist durch die gelblichgrünliche bis olivbräunliche Farbe, die bleibend spitzkegelige Form des Hutes (höher als breit) und die aufsteigenden schmalen Lamellen gut charakterisiert. Das Fehlen des nicht seltenen Pilzes im Verzeichnis der Pilze Sachsens dürfte wohl auf einem Versehen beruhen.

Figure 16 - A good description of ***Psilocybe semilanceata*** mushrooms from Saxony, Eastern Germany (1952).

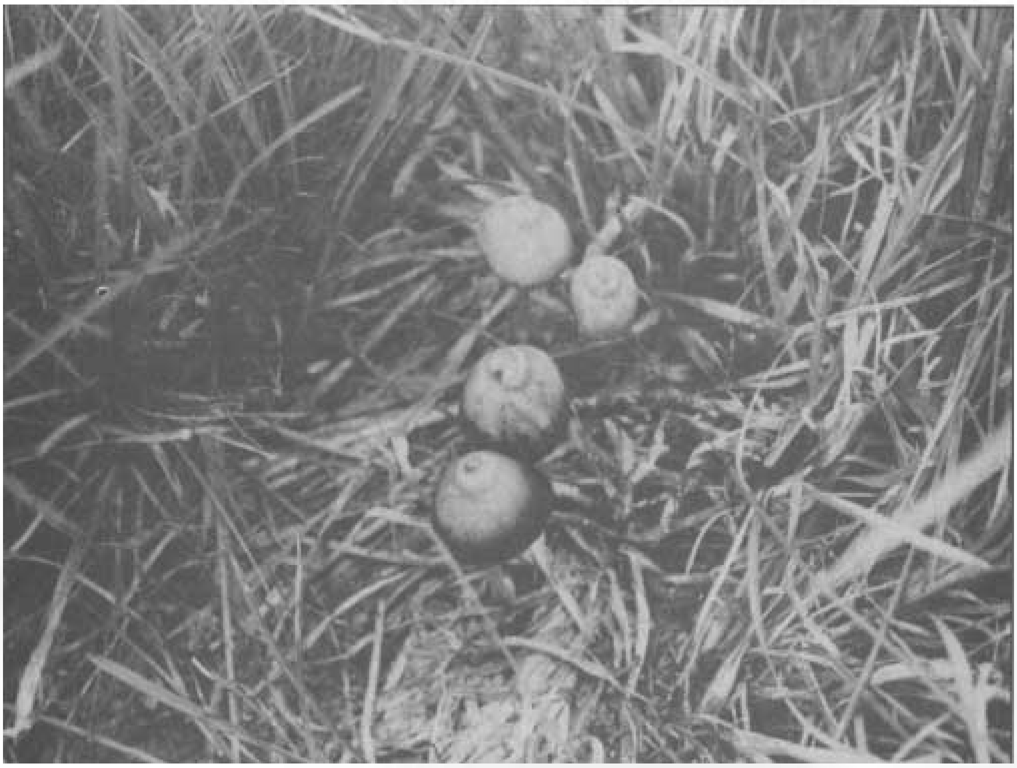

Figure 17 - ***Psilocybe semilanceata*** on grassy soil.

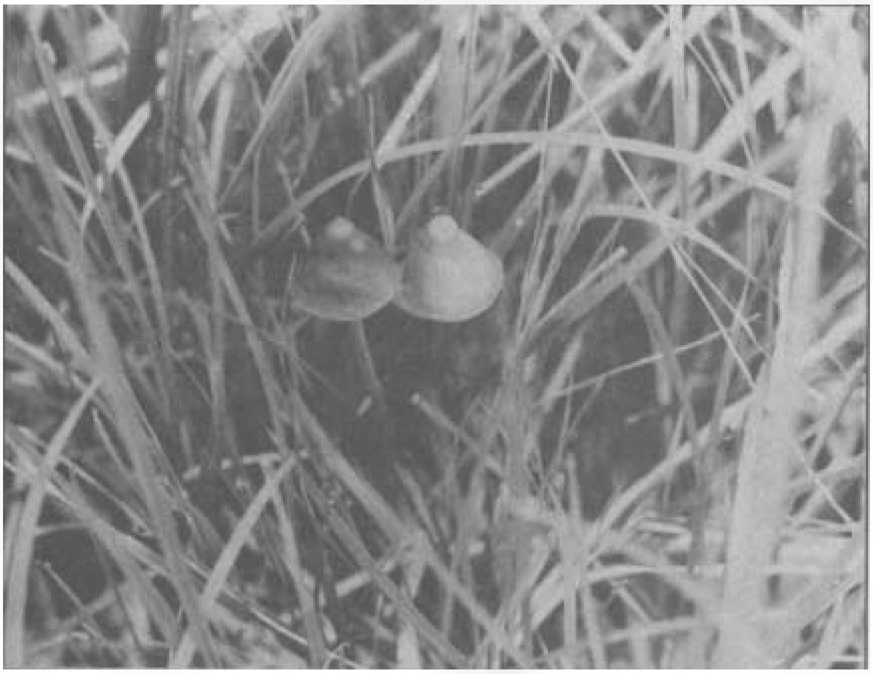

Figure 18 - ***Psilocybe semilanceata*** hidden in high grass.

On the other hand, a second experiment involving about half the previous dosage stood out because of a surge of memories and the simultaneous re-experience of childhood emotions, along with some curious feelings of melting and merging:

> *One day in late summer I was out on a nature walk and ingested 0.6 g of pulverized mushrooms. The weather was warm and sunny and I was walking through open areas near my hometown, were I had often played as a child. Suddenly, I experienced an emotional state most accurately described as child-like wonder and amazement about the surrounding forest. The area nearby appeared in very sharp contrast and my visual perceptions seemed fresh and pure. Suddenly I remembered in vivid detail just how small the trees had been decades ago and how I never observed any other plant growth there before dark, which had sometimes frightened me. At the*

> *same time, my body movements felt much more elastic and childlike. This delightful state of reliving my childhood lasted for about two hours. On the way home I noticed a small calf out on the pasture.*
>
> *The calf evoked a great amount of empathy in me, when I noticed how much it was bothered by pesky flies. These feelings of compassion culminated in a brief experience of completely merging with the calf. I found it to be rather strange and quite uncomfortable. After four hours, the effects subsided without any lasting side effects.*

Finally, a third mushroom experiment with *Psilocybe semilanceata* in Oregon led to an experience of complete identification with a person from the 19th century:

> *We collected a large number of "liberty caps" in a pasture near Astoria. Later on, back at our lodgings, I ate no more than six fresh mushrooms. The key stimulus for the following experience was provided by a water color painting of an elegant lady from the 19th century that captured my attention completely. Suddenly I knew that I was re-living an earlier incarnation, a life that began when I was born in Germany in 1813.*
>
> *My name was Alexander Schmitt, and I knew that I had died in 1871. As a child, I travelled by boat to North America, together with my parents and other immigrants. In the United States, I changed my last name to Smith. I was a logger in a small Kentucky town named Sharpville or Shopville. My life there was hard and full of sacrifices and I drank a lot of alcohol. These circumstances of my existence were indicative of my lifestyle, which included beating my wife and otherwise mistreating her like the tyrant I was. As the experience deepened, I completely identified with the person of Alexander Smith. During these moments I forgot my native German altogether, and my thinking processes unfolded entirely in English. In this manner, I eventually experienced the last hours of Alexander Smith's life. I was lying in bed on several white sheets and was very ill. Suddenly I knew that my wife had poisoned me, to put an end to my continuous degrading treatment of her over the years. I knew that I did not have long to live. I was about to die. Fortunately, the experience ended before I had to face the final struggle against death. Today, over three years later, this unique experience is still etched into my memory in vivid detail.*
>
> *The experience's emotional impact has not diminished with the passage of time.*

Such experiences of earlier incarnations cannot be explained in terms of the accepted tenets of western science. In any case, a thorough attempt should be made to research the existence and historic accuracy of the locations and persons involved. The individual who experienced the events described above had never been to Kentucky, did not know whether or not a town named Sharpville or Shopville has ever existed there and had never before had the slightest interest in this U.S. state. Due to his strictly atheistic upbringing, he had never thought such experiences possible. S. Grof, however, has described similar sequences and emphasized that they can occur quite unexpectedly under the influence of hallucinogens. He also noted that such experiences are not exactly unusual, when an individual experiences repeated applications of hallucinogenic substances.

In closing this section, I would like to present a short account of an experience that illustrates how the effects of psychotropic substances can vary across individuals, depending on the setting in which the experience takes place:

> *After ingestion of 0.6 g of pulverized mushrooms in orange juice, the effects began to manifest after about 30 minutes: An endless sequence of images behind closed eyes. At the same time, no distinctly euphoric nor dysphoric emotional states were noted; the reaction to these images is most fittingly described as "temporary amazement". The initial images of entwined ornaments changed with the passage of time and became plants, some of whom had several surreal characteristics not known to exist on Earth. I believe these images reflected my longstanding preoccupation with the world of plants. Then, when a mirror was placed in front of me, I perceived "a gloomy-looking fellow with a fixed gaze". Then I admitted, somewhat reluctantly, that this impression did, in fact, reflect my everyday demeanor and that I usually did not make it*

easy for others "to see behind the facade ". The experimental guide confirmed my own impressions. Prior to this incident, we had never discussed this issue.

The Psychotherapeutic Potential of Psilocybin's Psychotropic Effects

The preceding account of an experience by a 67-year-old mycologist contains elements that illustrate the beneficial potential of psilocybin's psychotropic effects as an adjunct to psychotherapy. We will return to a discussion of these benefits in Chapter 9.

In accordance with their strong psychoactivity, chemical analyses of *Psilocybe semilanceata* specimens have revealed high levels of psilocybin. It is safe to say that this species has been more thoroughly studied than any other *Psilocybe* species, including the Mexican species, whose dried mass is known to contain 0.2 - 0.6 psilocybin.

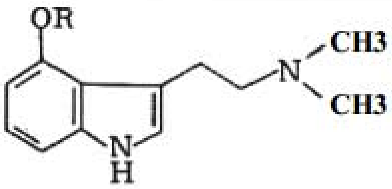
Collections of *Psilocybe semilanceata* from England, Scotland, Norway, Finland, Belgium, Holland, Germany, France, the United States as well as from Switzerland and the former Czechoslovakia have, for the most part, been extensively analyzed. It was discovered that the combined analysis of several dried mushrooms for alkaloid content yielded an average value of 1% psilocybin of the dry weight, regardless of country of origin. The issue of chemical race has been hotly debated with respect to other species, such as the fly agaric mushroom. But in contrast to plants, such a phenomenon has not yet been proven to exist in the higher mushroom species. So far, there is no evidence to support the notion that the basic chemical make-up of a species can vary dramatically from sample to sample. Among the species discussed here, *Psilocybe semilanceata* and *Inocybe aeruginascens* (see Chapter 3.4) appear to be the two species with the lowest degree of variability in psilocybin content across samples. The first three analysis results shown in Table 1 represent data from my own research conducted in the course of a workshop with other investigators in Prague.

Table 1
Average Psilocybin Content of Dried *Psilocybe semilanceata* Samples.

Origin	Psilocybin (%)
1. Dubener Marshlands, Eastern Germany	0.96
2. Prague, Czech Republic	1.05
3. Krasna Lipa, Czech Republic	0.91
4. Norway	0.95
5. Pacific Northwest, USA	0.93
6. The Netherlands	0.97

Fresh mushrooms are about 90% water, that is, one gram of mushroom material contains an average of 1 mg of psilocybin.

Psilocin, a comparatively less stable compound, is the phenol analogue of psilocybin (see Figure 19, p. 27) and thus oxidizes much more readily than psilocybin. *Psilocybe semilanceata* contains only trace amounts of psilocin, if any at all.



(1) **R** = H_2PO_3
(2) **R** = H

Figure 19 - Structural formulas for psilocybin (1) and psilocin (2).

On the other hand, baeocystin as the Biochemical precursor of psilocybin is found in all fruiting bodies of the

Psilocybe species. The precursor has a hydrogen atom where psilocybin's only CH_3 group is located; the average baeocystin content is 0.2% of dry weight. In 1967, Leung and Paul reported the isolation of baeocystin from fruiting bodies of *Psilocybe baeocystis* Singer & Smith in North America. In 1977, Repke and Leslie also found the substance in a *Psilocybe semilanceata* sample from the same place of origin.

Some investigators have found differences in alkaloid content when comparing single fruiting bodies from the same location.

Table 2

Alkaloid Content of Dried Mushrooms from a Location in the Dubener Marshlands of Eastern Germany (Selected Results)

Dry Weight (mg)	Psilocybin (%)	Baeocystin (%)
18	1.25	0.34
30	0.96	0.21
70	0.72	0.19
85	0.90	0.10

Smaller mushrooms almost always contained more alkaloids than larger specimens. This fording was then confirmed by another study using considerably larger amount of investigative materials (40 mushrooms). Moreover, exceptionally high concentrations of baeocystin have been shown to accumulate in the caps of fruiting bodies that contain the alkaloid. In addition, one mushroom sample from Finland deserves special mention due to its unusually high psilocybin content of 2.37%!

Early controlled studies of the psychoactivity of various species in the former Czechoslovakia concluded that *Psilocybe semilanceata* is a more potently psychoactive species than *Psilocybe bohemica*, even though both species were found to contain the same amounts of psilocybin. Thus, researchers hypothesized that the mushrooms are likely to contain additional substances that contribute to the overall psychotropic effect. This hypothesis is supported by the fact that considerable amounts of baeocystin are consistently found in samples of *Psilocybe semilanceata*. I am also aware of an experiment whose results showed that 4 mg of baeocystin caused mild hallucinations for three hours, while 10 mg of baeocystin were found to be about as psychoactive as a similar amount of psilocybin.

The Long Shelflife of Psilocybin

As part of dried mushroom material, psilocybin is a remarkably durable substance. A sample of desiccated mushrooms dated 1869 from a Finnish herbarium was still found to contain 0.014% of psilocybin. On the other hand, no alkaloids were founds in another sample dated 1843. Unfortunately, it is no longer possible to determine the methods used in drying these samples. Temperatures over 50°C cause psilocybin to break down into its derivatives. In laboratory settings, mushrooms are usually dried at room temperatures. Sometimes, fruiting bodies are also freeze-dried for analysis. Freeze-dried mushrooms, however, have a highly porous texture that causes the alkaloids to break down relatively quickly, if the samples are stored at room temperature (20°C). For that reason, freeze-dried samples for biochemical analysis are stored at -10°C prior to alkaloid extractions or chromatography testing. In addition to the reports from Finland, investigators in North America have noted that psilocybin's decay rate is slowest in *Psilocybe semilanceata*, compared to other species.

3.2 - *Psilocybe cyanescens*: Potent Mushrooms Growing on Wood Debris

At least one other *Psilocybe* species in addition to *Psilocybe semilanceata* is known to exist in Europe. At this point, I must emphasize that the differentiation of single species within the *Psilocybe* genus is subject to considerable controversy among eminent taxonomists. For example, there are different methods of distinguishing the *Hypholoma* genus from the *Stropharia* genus.

The Widespread Distribution of *Psilocybe cyanescens*

While *Psilocybe semilanceata* is a species that has long been clearly defined and is well known by this name, there are, according to Krieglsteiner, other strongly bluing mushrooms that can be described as belonging to the "*Psilocybe cyanescens* complex". These are all mushrooms that grow on raw compost and plant debris.

In accordance with current states of knowledge, the following names in the literature are merely synonyms for *Psilocybe cyanescens* Wakefield emend. Krieglsteiner:

- *Hypholoma cyanescens* R. Maire
- *Hypholoma coprinifacies* (Rolland ss. Herink) Pouzar
- *Geophila cyanescens* (R. Maire) Kuhner & Romagnesi
- *Psilocybe serbica* Moser & Horak
- *Psilocybe mairei* Singer
- *Psilocybe bohemica* Sebek

The classification of these synonyms is particularly difficult, because the mycologists involved provided detailed descriptions for isolated collections of fruiting bodies only, followed by comparisons with mushrooms found at other locations, using dates provided in the literature. Under the best of circumstances, an analysis was performed on dried samples from different herbariums. However, the microscopic data pertaining to the *Psilocybe* species are poorly delineated and oftentimes overlap. It is therefore imperative that additional mycological studies of *Psilocybe cyanescens* be performed. To this end, fresh mushroom samples from various European locations should be used, and biochemical methods must be included in the investigation. Guzman's division of *Psilocybe cyanescens* by geographic area, however, definitely turned out to be inaccurate. According to his system, - North Africa was home to *Psilocybe mairei*, while *Psilocybe cyanescens* were found in England and Holland and *Psilocybe serbica* supposedly grew in Serbia and Bohemia. The geographic distribution of the entire species seems to cover a vast area, with variations along climate and terrain at locations where samples were collected. Such disparate morphologies are to be expected when dealing with "young" species, that is, species that have not yet firmly established themselves and are still expanding into new locations.

Figure 7 (p. 14) displays locations in Europe and North Africa where samples of *Psilocybe cyanescens* have been found.

Spores Introduced From Overseas?

In this section I would like to discuss several aspects of the bluing *Psilocybe* mushrooms. Detailed information about several isolated sample collections has been presented by Krieglsteiner.

A description of any mushroom species becomes valid only after a Latin diagnosis of the collected sample has been published in a mycological journal, along with distinctive characteristics in relation to other species.

In 1946 Wakefield described as *Psilocybe cyanescens* Wakefield a sample of bluing dark-spored mushrooms collected at the botanical gardens in Kew, England. It had been suggested that those mushrooms occurred adventitiously, that is, that the spores had been imported from overseas together with other plant materials. The presence of such mushrooms in botanical gardens had been observed quite frequently, and such imports are likely whenever the mushroom in question has never before been found in surrounding areas. The possible importation of *Gymnopilus purpuratus* is described elsewhere (see Chapter 3.5).

The mushrooms displayed a much more intense blue staining reaction than *Psilocybe semilanceata*. They were observed growing on small pieces of wood in the forested areas of Kew Gardens during the fall season for several years. Among the mushrooms' most notable features are their undulating, twisted caps. Guzman believes that specimens collected in British Columbia and the Pacific Northwest of the United States (Northern California, Oregon, Washington) are identical to those found in Kew Gardens (see Figure 24). Indeed, all of the macroscopic and some microscopic descriptions and photographs match the mushrooms found in England. However, conclusive proof of identity can be provided only by results from DNA analyses and cross-breeding experiments with single-spore mycelia. I will elaborate on this method in a later section.

In 1975, fruiting bodies of this species were also discovered in Holland. Additional bluing mushrooms growing gregariously on grass and decaying reeds were found in the Jura Mountains of Switzerland in 1972 (MTB 8511). Other samples are known to have been collected in the Steiermark region of Austria in the fall of 1976, as well as on the Mediterranean island of Corsica in 1972 and 1984.

On several occasions, a number of fruiting bodies classified as *Psilocybe cyanescens* were also discovered in Germany (see Figure 23, p. 32).

More elaborate descriptions of several such collections are provided below:

> On October 31, 1983 considerable quantities of fruiting bodies in all stages of development were found in the lower regions of Bavaria (MTB 7542). Interspersed with grass, the mushrooms grew along a 100-yard stretch right next to an old garbage dump forming colonies, some small and others larger, that were partially intertwined. They were found scattered across decaying plant materials, such as leaves, twigs and mulch. There were greenish and distinctly bluish stains on the caps, and most notably a bluish color near the base of the stem. Other fruiting bodies quickly developed blue stains in reaction to being handled, even in very cool temperatures.

The description of *Psilocybe cyanescens* below is somewhat condensed, but essentially applies to all other collections, while the relative measures and sizes may vary:

> *Caps*: 5-40 mm broad, conic at first, with cortinate fibrils ascending steeply to the stem, but fading quickly, bell-shaped later on, partially with an acute umbo. Later expanding to plane, with undulating or wavy margins, no remnants of veil, also broadly convexed to umbonate in older mushrooms. Deep chestnut brown when fresh and moist, fading to a whitish color when drying, with stains of bluish to blue-green coloration.
>
> *Gills*: Attachment adnate to broadly subdecurrent, color light to dirty beige when young, later on changing to cinnamon-purple brownish color due to maturation of spores. Blue staining reaction is slight in response to pressure.
>
> *Stem*: 30-85 mm long, uniformally thick at 1.5-3 mm. Stems and mycelial fibers turn blue in response to touch, if blue stains not already present.
>
> *Odor*: Somewhat like flour or potatoes.
>
> *Spores*: 6-8 x 9-14 µ.

In 1976, bluing mushrooms growing on plant debris were found in the Saarland region of Germany. Other collections came from the Southern regions of the Black Forest (MTB 7515, 1959, 1963), as well as the Vogtland area (1979) and the Rheinland area (MTB 4706, 1982). Similar mushrooms were also discovered near Hamburg (MTB 2428, 1983) and Bremen (1982, 1983). The latter collections are especially interesting, because the greenhouses at the Rhododendron Park and People's Park in those cities provided layers of wood chips during the fall which enabled the mushrooms to fruit much more prolifically (thousands of mushrooms) than they did naturally in surrounding areas, where the species was also fruiting in several locations. These findings most likely indicate the presence of a similar, imported species, because native fruiting bodies require exposure to the shock of colder temperatures of fall in order to develop from the mycelia. For instance, other wood chipdwelling species have been reported from the Pacific Northwest of the U.S., such as *Psilocybe stuntzii*, *Psilocybe baeocystis*, *Psilocybe pelliculosa* and others (also see Chapter 7.1). *Psilocybe caerulescens* Murr. from Mexico is also related to these species. This was the first *Psilocybe* mushroom to be recognized as psychoactive by Wasson in the course of his self-experiment on June 29, 1955.

Very little is known about the chemical composition of the collections cited above. I analysed a few mushrooms from collections found in the Rheinland area of Germany in 1989. The results were as follows:

Psilocybin:	0.51% of dried mushrooms
Psilocin:	0.08% of dried mushrooms
Baeocystin:	0.04% of dried mushrooms

A few other analyses of German mushrooms yielded similar results. These values were well within the range of concentrations of alkaloids found in Mexican species. The most extensive studies on distribution, psychoactivity and chemical compounds of *Psilocybe cyanescens* complex were conducted in the former Czechoslovakia, where the mushrooms are generally known as *Psilocybe bohemica*, a name which is also used in the text below.

An Amazing Discovery Near Poricko

Kubicka first discovered the species on December 6 and 13, 1942 in the Kresicky Creek Valley village of Poricko v Pozavi near Sazava (Czech Republic). In 1950, mycologist Herink described the mushrooms in detail. He also believes that Fries classified mushrooms of the *Psilocybe cyanescens* complex as *Psilocybe callosa* during the 19th century. On November 11, 1986 I had the opportunity to work with Herink and other Czech mycologists on a mycological field research project at the location, where we found 440 fruiting bodies (550 g or 19.6 ozs). Covering a segment almost two miles long, the species was fruiting among nettles along both sides of the creek on wood chips of *Carpinus*, *Alnus* and *Salix*, on raw compost mixtures of *Picea*, *Pinus* and *Larix* needles, as well as on decaying pine cones. Several specimens up to 15 cm (6 in.) tall with caps up to 5 cm (2 in.) broad were found growing on a rotting log whose underside was exposed to the running water. A water-loving *Psilocybe* species, it primarily fruits in late autumn (see Figure 21, below), when short night frosts induce maximum possible fruiting. The brown caps are strongly hygrophanous and their color fades to a white-milky brown when dried. Its odor has been compared to anything from radishes to poppies. In my experience, the odor is highly variable and thus difficult to define. Young, dry mushrooms develop intensely blue stains in response to handling, while older fruiting bodies tend to be found at the location with dark blue stains already in place. It is remarkable that the mushrooms were fruiting at the same location near Poricko for so many years in a row, producing a large number of fruiting bodies each year. Unfortunately, in recent years the location was partially destroyed, due to construction of a road.

By late 1982, the mushroom species had been found at 51 locations in the former Czechoslovakia, with only seven of them located in Bohemia, 40 in Moravia, and four in Slovakia. Elevations vary from 200 m to 700 m (600 ft to 2,100 ft) above sea level, with only two locations known to exist above 700 m (2,100 ft). By this time, 112 collections had been reported, 44 of which came from the classic location near Sazava.

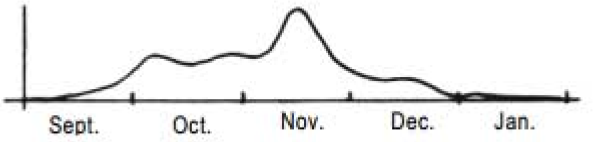

Figure 21 - Fruiting curve of ***Psilocybe cyanescens*** based on observations at several locations in the former Czechoslovakia

The mycelia make use of different kinds of plant debris and even grow on wet cardboard, where they develop into rhizomorphs just like they would in nature. Rhizomorphs are thick strands of mycelia that serve to transport nutrients and water. They also develop intense blue stains (see Figure 22).

Impressive Experiences

Psilocybe bohemica is a very psychoactive species. Its effects are vividly documented in the following account of one natural scientist's experience as part of controlled clinical trials in Prague:

About 30 mg of psilocybin in mushroom tissue was prepared in hot water, with effects already noticeable ten minutes after ingestion. I grew increasingly quiet. At first, my legs began to tingle, then my underarms as well. Aside from a deeper breathing rhythm, few other somatic effects were noted. Initially there were fits of laughter caused by unusual cognitive associations; this laughter also affected the two "sober" guides. A growing hyperacuity interfered with the ability to listen to music, so that Vivaldi's "Springtime" caused painful stabs inside the brain. I compared the pain to that caused by a "sawing knife". The experimenters appeared bloated and yellow... Existing bodily characteristics, such as thinning hair stimulated a person's illusionary transformation into a monk with tonsure. Their voices also appeared reverent and, from a somewhat paranoid point of view, these gentlemen at times seemed to be working a switching station that, for some reasons, was my enemy. At the same time, I found both of them to be quite likeable. During this time period, the other female subject perceived fantastic images of moving colors and saw visions of her whole life unfolding behind closed eyes. During this period, I had the distinct impression that an electrical current was flowing through my body, which was not an uncomfortable sensation. About three hours later, the gentlemen retired to the kitchen and the nature of the experience changed quite drastically.

> *At first I felt as if my legs were increasingly merging into the wall, a very comfortable experience. In a state of utter clarity of consciousness, I finally felt as if I had no body at all. I said. "The most descriptive expression is the experience of a pure soul". Using words as triggers, we were able to induce shared experiences of color visions and we travelled together around the word as well the spiritual realm. She made a clearly telepathic statement about my hometown, which I could not fathom or interpret at the time, nor could I do so later on. While under the impression that the thinking process itself was something supernatural, I was filled with confidence when I realized without a doubt that death itself was but a levitation of the soul, which may or may not entail looking down upon the "normal" world. I did, however, anxiously reject her offer to see into my future and tell me about what she learned. Yet I knew that she was already seeing such things.*

The above account vividly illustrates the cosmic-mystical aspects of the mushrooms' effects. Such effects have frequently been described following ingestion of high doses of hallucinogens, especially in cautious and protective environments ("setting") coupled with a positive, internal mood ("set") primed by careful preparation. Of course, the detailed content of such experiences varies across individuals. Pahnke's masterful study during Good Friday Services in 1962 has become a famous event in the history of research into these states of consciousness.

Three years later, a remarkable range of effects was observed in the same participant of an experiment conducted in Prague, where mycelia from *Psilocybe bohemica* were used. Due to an analytical error, the four participants each ingested 72 mg of psilocybin, plus some psilocin, instead of the intended dosage of 30 mg of psilocybin each:

> *Days before the experiment, I already began to suspect that this experience would not evolve as smoothly as it had three years ago, given the amount of personal stress I had suffered over the previous two months. However, I had faith in the expertise provided by psychiatric guidance. Prior to the experiment, I asked the psychiatrist about the possible causes underlying my seeming inability to fully experience the unfolding of visual imagery. He brushed aside my question with a short and terse reply: "Resistance", which only heightened my feelings of anxious tension.*
>
> *After ingestion of the hot preparation, fifteen minutes passed until the sudden onset of its effects. I ceased to perceive the music and sank into an autistic state devoid of visions which lasted for three hours. This state was subjectively experienced as one of confusion with a partial loss of consciousness as well as the loss of a sense of time and place. This torturous period, however, did not include any rough somatic disturbances. After I woke up, I felt like a broken machine; only the compassion of the other participants, which were also suffering, helped to clear my head temporarily. My experimenter attempted to counterbalance these effects and to provide a firmly*

> *grounded focus of reality, but his efforts were unsuccessful in the long run. I felt as if I was extremely drunk, except there was none of the aggression typical of alcohol intoxication. Soon afterwards, I began to project my emotions onto the psychiatrist. I saw him undergo illusionary changes; initially he appeared to be a dominant rooster which transformed into a punk rocker. Then I felt that he would understand what I was going through, given his extensive background and experience with psycholytic therapy. So I asked him, if the two of us could retire to another room. When he consented, I began to undergo a psychic split. The sound of my voice was strange and whiny. I felt as if part of me had split off and become an observer, while the rest of my prone body had assumed the position of an infant, sucking on a finger and crying, crumbling up tissue papers at the same time. On the psychoanalytic level, an extraordinary experience began to unfold. I became conscious of all recent and past conflicts, especially those involving my parents. This part of my personality articulated and worked through the emerging conflicts. Even though one might assume this process was facilitated by the psychiatrist, this was not the case. In the semidarkness I perceived him as my deceased grandfather, as a human skull and as an American football player, whose armor I recognized as a projection of my own uptight personality.*
>
> *Afterwards I looked at my reflection in a large mirror and reconciled my differences with myself as the two halves of my personality merged into one. I saw a soft and tearful face and soon realized that the person I was looking at was none other than myself, that I had learned to accept myself, in spite of all my problems. At the time I also noticed that my self-disciplined behavior was overly exaggerated, a trait generally judged as unfavorable by those around me. I resolved to become more relaxed and carefree in attending to my daily routines. I believed this psychological insight to be a revelation. With my eyes closed, I saw images of translucent vessels atop a brilliantly blue surface. In the weeks and months after the experiment, those around me noticed that my behavior had changed to become more relaxed, which was mentioned spontaneously on several occasions.*

The experience of an initial, painful delirium illustrates a resistance to dealing with the conflicts that invariably emerge in response to high dosages - conflicts that were resolved through an intense psycholytic catharsis (also see Chapter 9). A psychedelic experience ensued as both parts of the divided personality were merged into a whole. This is a decidedly positive outcome of a psycholytic episode with corresponding therapeutic benefits - a result that was entirely unintended (!). Personal stress prior to the experiment apparently facilitated the manifestation of deep-seated conflicts and issues that might otherwise never have been dealt with. With the exception of the attending psychiatrist, outside observers appraised this experience as a "bad trip". The subject, however, thought the experience to be enlightening and illuminating, even five years after it took place. Grof describes very similar reactions to LSD therapy. After "going through Hell", subjects proceed to reintegrate their personality at a higher level of consciousness, while experiencing visionary images of clear, bright lights and illumination.

Table 3
Concentrations of Psilocybin and its Derivatives in Psilocybe bohemica (% of Dried Mushrooms)

Specimen #	Weight (mg)	Psilocybin	Psilocin	Baeocystin
1	31	1.34	0.00	0.01
2	90	0.94	0.01	0.01
3	104	0.41	0.00	0.02
4	175	0.90	0.00	0.01
5	200	0.71	0.01	0.02
6	220	0.37	0.00	0.01

Distribution Patterns of *Psilocybe cyanescens* in the Wake of Environmental Changes

In 1973, Semerdzieva and Nerud first reported the existence and qualitative content of psilocybin in collections of *Psilocybe bohemica*. This research team reported psilocybin levels of up to 1.1% in dried samples. Results from my own studies also revealed variable levels of alkaloids in different mushrooms collected at the one location near Sazava.

In spite of the intense blue staining reaction, there is very little or no psilocin in mushrooms of the European *Psilocybe cyanescens* complex. By chemical-taxonomic standards, European collections are very different from *Psilocybe cyanescens* samples collected in the Pacific Northwest of the United States. The latter are known to contain up to 1% psilocin (dried mushrooms) as well as an equally high level of psilocybin (for a total alkaloid level of 2%), making it one of the most potent species in North America. The study of extracts derived from these mushrooms revealed that enough psilocin was present for the oxidized compound to be visible on a thin-layer chromatography plate. This was not the case when similar analyses were performed on mushrooms collected in the former Czechoslovakia. However, mushrooms from both countries contain similarly low levels of baeocystin.

Generally we can say that this potently psychoactive and conspicuous species is in the process of expanding its habitat across Europe. Increasing use of fertilizer, the acidification of the soil in many regions and the presence in any wet forest or park of a variety of fertile substrates, such as mulch, not dependent on the presence of dung, are all factors that will likely help *Psilocybe cyanescens* achieve a remarkably wide area of distribution in the future.

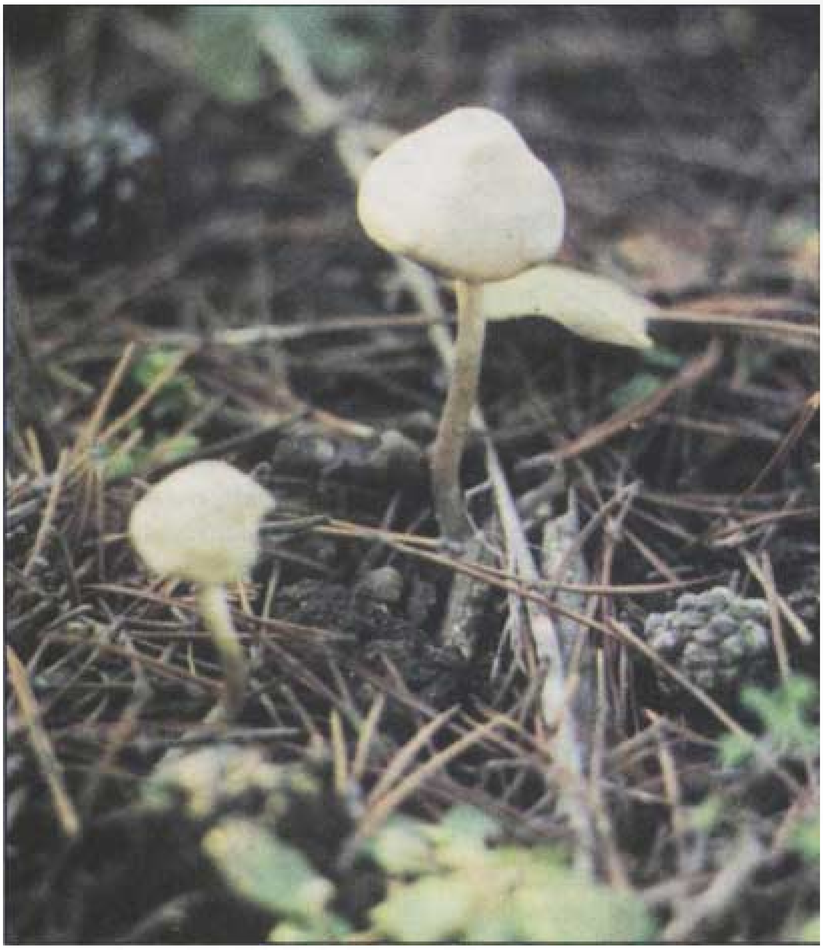

Figure 26 - ***Psilocybe bohemica*** on twigs and compost.

3.3 - *Panaeolus subbalteatus*: Mycology and Myths about the *Panaeolus* Species

Stories about involuntary intoxications with the dark-spread dung-inhabiting mushrooms (genus *Panaeolus*) in various regions of the world have been in circulation since at least the early 19th century.

> *In 1816, an impoverished man collected mushrooms in London's Hyde Park which he thought to be edible white mushrooms ("champignons ", Agaricus bisporus). Soon after ingesting these mushrooms, his field of vision darkened and he saw fog while feeling lightheaded and dizzy.*
>
> *Trembling, he sank into his chair. He felt all his strength draining from his body and he grew oblivious to his surroundings and no longer knew where he was. Some time later, the feelings of dizziness subsided, and his heart rate slowed down until he was finally able to fall asleep.*

The symptoms were later attributed to "*Agaricus campanulatus* Linnaeus ", which the man had mistaken for champignons. The same species had been responsible for a similar case of intoxication that happened about a year earlier. Both accounts are highly reminiscent of the 1799 intoxication with *Psilocybe semilanceata* from St. James Green Park (see p. 15). This would seem to be quite logical, as there are psilocybin-producing mushrooms even among the genus *Panaeolus*. However, the question which of the 15 European species actually produce the psychoactive substance is an issue that remains the subject of considerable scientific controversy. Even though I cannot offer any decisive or final evidence towards the resolution of this problem, there are some fairly conclusive results from modern biochemical analyses (see Table 4 below) of mushrooms that were clearly identified or obtained from herbariums, where certain species were known to have been deposited. Specifically, many American species within the genus *Panaeolus* do not appear to be the same as European species with the same name.

At this point, I would like to present some historic cases of *Panaeolus* intoxications. A typical hallucinogenic experience blamed on the accidental ingestion of *Panaeolus papilionaceus* (Bull.:Fr.) Quel. occurred in Maine, USA, in 1914.

Below is an abridged version of the description of effects by a Mr. W.:

> *On July 10, 1914, I gathered a good mess of the mushrooms (Panaeolus papilionaceus) and had them cooked for dinner. ... They were all eaten by Mrs. Y. and myself. Peculiar symptoms were perceived in a very short time. ... A little later, objects took on peculiar bright colors. A field of redtop grass seemed to be in horizontal stripes of bright red and green, and a peculiar green haze spread itself over all the landscape... Soon both of us became very hilarious, with an irresistible impulse to laugh and joke immoderately, and almost hysterically at times. ... I then had a very disagreeable illusion. Innumerable human faces, of all sorts and sizes, but all hideous, seemed to fill the room and to extend off in multitudes to interminable distances, while many were close to me on all sides. They were all grimacing rapidly and horribly and undergoing contortions, all the time growing more and more hideous. Some were upside down. The faces appeared in all sorts of bright and even intensive colors - so intense that I could only liken them to flames of fire, in red, purple, green and yellow colors, like fireworks. ... The entire experience lasted about six hours. No ill effects followed. There was no headache, nor any disturbance of the digestion.*

During the winter of 1915, a species of *Panaeolus* spontaneously appeared in a mushroom greenhouse in New York. These fruiting bodies were accidentally eaten together with the champignons that were cultivated there. This error led to cases of intoxications so remarkable that Murrill described the mushroom as *Panaeolus venenosus*. Some time passed before it was discovered that this species had previously been described as *Agaricus subbalteatus* B. & Br. from England in 1861. The combination term that is in use today, *Panaeolus subbalteatus* (B.& Br.) Sacc. was first published in 1887.

Other cases of intoxications with similar symptoms caused by the *Panaeolus* species have been reported in the United States (1917), as well as from Australia (after 1940), where the species involved was described as "*Panaeolus ovatus* Cooke & Massee".

In 1939, these reports induced Schultes, in agreement with Linder's classification experiments, to publish as *Panaeolus sphinctrinus* (Fr.) Quel. the *teonanacatl* mushroom described in the Mexican literature from the 16th and 17th centuries.

However, Wasson, Heim and their collaborators, as well as Singer, were unable to document the usage of *Panaeolus* mushrooms in Mexico, in addition to their reports about the usage of psychoactive *Psilocybe* species from the 1950s. By 1959, even Guzman referred to this species as "the false teonanacatl". So far, he has been unable to document native usage of any *Panaeolus* species in Mexico. In fact, the natives of Mexico consider bluing, hallucinogenic *Panaeolus* mushrooms to be poisonous.

Despite the poisoning case reported in England, the early German literature does not classify *Panaeolus* species as poisonous (see Figure 27). The *Psilocybe* species were treated similarly.

Figure 27 describes the mushroom's characteristics as accurately as Figure 3 (p. 6) depicts its habitus. More recent descriptions are usually less detailed and thorough than Michael & Schulz's from 1927.

In Germany, a case of intoxication with *Panaeolus* mushrooms was first reported in 1957 (see Figure 28). From today's perspective, it appears that the mushroom responsible for the intoxication was most likely *Panaeolus retirugis* (Fr.) Gill.

> *About 30 to 60 minutes after ingestion of the cooked mushrooms, the woman's field of vision began to quiver increasingly. At the same time, her pupils were extremely dilated. As she began to have difficulties breathing, she suffered a full-fledged anxiety attack. All objects appeared as if obscured by curtains. After the effects had subsided, no symptoms of lasting damage could be detected.*

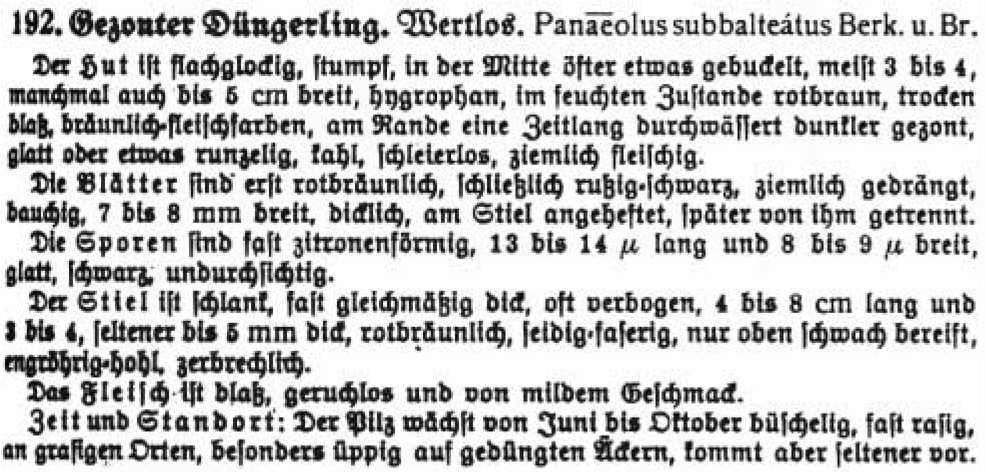
In 1970, another poisoning case with *Panaeolus subbalteatus* occurred in Leipzig. Similar to the 1915 incident in New York, the mushrooms spontaneously emerged among a culture of artificially cultivated mushrooms (*Stropharia rugoso-annulata* Farlow, in this case) and then were eaten by mistake. The description of its effects is somewhat peculiar.

Growing on Dung, Manure and Compost

The stories about intoxications as well as the very name "dung-inhabiting" mushroom offer clues about the kinds of habitats this species prefers to grow in.

At times, they grow directly on top of dung or on pastures that have been heavily fertilized. They are also found on trash heaps, on compost or on straw substrates where mushrooms are commercially cultivated. European *Panaeolus* species that produce psilocybin have a special attribute that differentiates them *Psilocybe* species: they very seldom develop blue stains when handled or injured. In his description of a Scottish case of intoxication in 1977, Watling mentions marked blue colorations along the caps of stems of *Panaeolus subbalteatus*, which also developed in reaction to pressure. According to my observations, the formation of blue stains is very rare. Reports from the Pacific Northwest United States also state that only one in a hundred mushrooms actually turns blue.

One controversial issue in the literature concerns the toxicity of one species: *Panaeolus foenisecii* (Pers.:Fr.) Kuhn. This species has previously been classified as *Psilocybe* as well as *Psathyrella*, and has been described as *Panaeolina* in contrast to *Panaeolus*, because it is a species that does not grow on dung, fruits only after the hay harvest, and develops spores that are purplish-brown and abrasive. Other *Panaeolus* species, however, have black spore prints when placed on white paper underneath a glass vessel to prevent dehydration. But, even the spores of *Panaeolus foenisecii* (Pers.:Fr.) Kuhn.do not all ripen at the same time, which can cause the gills to appear mottled. Due to the complications with taxonomic differentiation, there are certainly no reliable maps showing distribution patterns for the European *Panaeolus* species.



192. Gezonter Düngerling. Wertlos. Panaeolus subbalteátus Berk. u. Br.

Der Hut iſt flachglockig, ſtumpf, in der Mitte öfter etwas gebuckelt, meiſt 3 bis 4, manchmal auch bis 5 cm breit, hygrophan, im feuchten Zuſtande rotbraun, trocken blaß, bräunlich-fleiſchfarben, am Rande eine Zeitlang durchwäſſert dunkler gezont, glatt oder etwas runzelig, kahl, ſchleierlos, ziemlich fleiſchig.

Die Blätter ſind erſt rotbräunlich, ſchließlich rußig-ſchwarz, ziemlich gedrängt, bauchig, 7 bis 8 mm breit, dicklich, am Stiel angeheftet, ſpäter von ihm getrennt.

Die Sporen ſind faſt zitronenförmig, 13 bis 14 μ lang und 8 bis 9 μ breit, glatt, ſchwarz, undurchſichtig.

Der Stiel iſt ſchlank, faſt gleichmäßig dick, oft verbogen, 4 bis 8 cm lang und 3 bis 4, ſeltener bis 5 mm dick, rotbräunlich, ſeidig-faſerig, nur oben ſchwach bereift, engröhrig-hohl, zerbrechlich.

Das Fleiſch iſt blaß, geruchlos und von mildem Geſchmack.

Zeit und Standort: Der Pilz wächſt von Juni bis Oktober büſchelig, faſt raſig, an graſigen Orten, beſonders üppig auf gedüngten Äckern, kommt aber ſeltener vor.

192. *Panaeolus subbalteatus* Berk.u.Br.

The cap is broadly convex, obtuse, often with a slight umbo in the middle, usually 3-4 cm broad, sometimes up to 5 cm. Hygrophanous, reddish brown when wet, pale and brownish to flesh-colored when dry. Margins moist to watery at times, and banded with a dark brown stripe around the edges. Surface smooth or lightly wrinkled, bald, rather fleshy, no veil.

The gills are reddish brown when young, later on sooty or black, gill spacing is rather crowded and bulgy, gills are 7-8 mm wide and somewhat thick. Gills are initially attached to the stem, and detached later on.

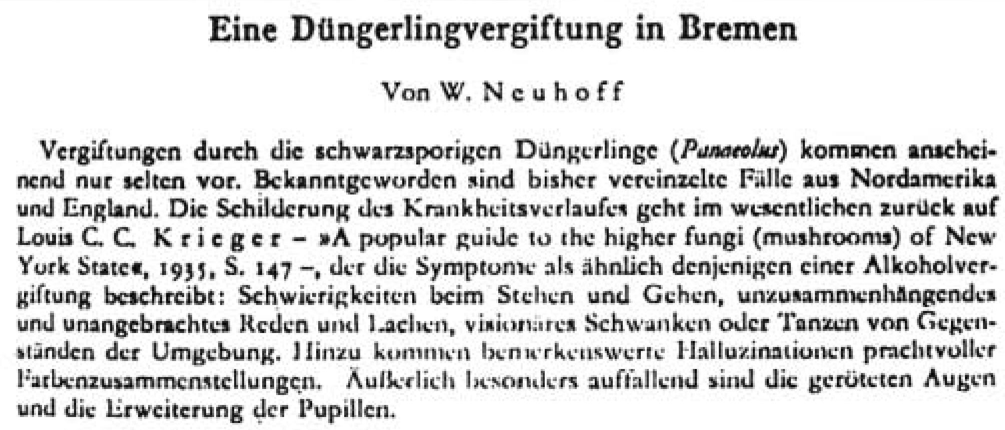
The spores are almost lemon-shaped, 13-14 µ long and 8-9 µ wide, smooth, black and opaque.

The stems are slender, 4-8 cm in length and uniformly thick (3-4 mm, sometimes up to 5 mm). Stems are often curvy and reddish brown in color; silky-fibrous with a slight ring at the top. Stems are narrowly tubular and break easily.

The flesh is pale and odorless with a mild taste.

Habitat and season: The mushroom grows cespitosely to gregariously from June through October in grassy areas. It particularly thrives on fertilized fields and pastures, but occurs there comparatively less often.

Figure 27 - Description of ***Panaeolus subbalteatus*** by Michael & Schulz from 1927 (with English translation below).



Eine Düngerlingvergiftung in Bremen

Von W. Neuhoff

Vergiftungen durch die schwarzsporigen Düngerlinge (*Panaeolus*) kommen anscheinend nur selten vor. Bekanntgeworden sind bisher vereinzelte Fälle aus Nordamerika und England. Die Schilderung des Krankheitsverlaufes geht im wesentlichen zurück auf Louis C. C. Krieger – »A popular guide to the higher fungi (mushrooms) of New York State«, 1935, S. 147 –, der die Symptome als ähnlich denjenigen einer Alkoholvergiftung beschreibt: Schwierigkeiten beim Stehen und Gehen, unzusammenhängendes und unangebrachtes Reden und Lachen, visionäres Schwanken oder Tanzen von Gegenständen der Umgebung. Hinzu kommen bemerkenswerte Halluzinationen prachtvoller Farbenzusammenstellungen. Äußerlich besonders auffallend sind die geröteten Augen und die Erweiterung der Pupillen.

Figure 28 - First description of a *Panaeolus* intoxication in Germany (1957). Symptoms are compared to those of alcohol poisoning, such as difficulties standing or walking, incoherent or inappropriate laughter and talking, and visions of objects moving or dancing. Other symptoms include remarkable hallucinations with splendid color combinations, as well as red eyes and dilated pupils.

Taxonomic Confusion

On May 25, 1986, in the village of Heringsdorf on the Eastern German Sea Coast, I found 147 fruiting bodies of *Panaeolus subbalteatus* in all stages of development. They were growing on a compost heap that originally contained horse manure. Unlike the *Psilocybe* species, *Panaeolus* mushrooms can be found anytime from spring throughout the fall season. The differentiation of *Panaeolus* species is further hindered because they are very hygrophanous, with caps whose colors can change from whitish to grey, or from reddish brown to a very dark black-brown. Older mushrooms on the compost heap had caps that had cracked with age, and margins that had curved upwards and were covered with spore dust. Only two mushrooms had blue-stained caps, and the stems did not change color in reaction to pressure. In the American literature *Panaeolus subbalteatus* has been labeled "*Panaeolus variabilis*", because some of the stems imitate the appearances of other mushroom species and thereby contribute to the taxonomic confusion. The species is also known to grow in the immediate vicinity of *Panaeolus foenisecii* (Pers.:Fr.) Kühn., creating more opportunities for mistakes, especially if the mushrooms are not closely inspected. The caps of *Panaeolus subbalteatus* become flat as the mushrooms age, a feature that is taxonomically significant.

The cap's long, watery marginal zone gives the mushroom its name. Only the psilocybin-producing species will be discussed in more detail below. Results from recent comprehensive analyses clearly show that *Panaeolus subbalteatus* is the most important psychoactive European species among the genus *Panaeolus*. Ola'h's world monograph about the genus *Panaeolus* was published in the 1960s and has caused much confusion, since he described a number of species as "latent psilocybin-producers". He proposed, for example, that *Panaeolus foenisecii* occasionally produces psilocybin. All *Panaeolus* species share one characteristic that differentiates them from all other species discussed in this book: They produce 5-substituted indole compounds, such as serotonin and its biochemical precursor, 5-hydroxytryptophan. Serotonin is a compound widely found in animals and humans. It acts as a neurotransmitter in the brain, even though not all of serotonin's effects have been entirely understood. It should be noted, however, that both serotonin and 5-hydroxytryptophan are completely inactive when taken orally. When performing paper or thin-layer chromatographies, both of these substances can easily be mistaken for psilocin. It is remarkable that Ola'h's results contradict current findings, in that his data frequently showed the existence of psilocin in *Panaeolus* species!

More recent studies of carefully identified mushroom material from the European *Panaeolus* species did not document substantial amounts of psilocin in these samples. Also, "chemical races" associated with specific species could not be established. I believe that almost all accidental intoxications can be traced to ingestion of *Panaeolus subbalteatus*, with the possible exception of one case caused by an imported tropical species. Very little is said in the literature about *Panaeolus retirugis*, its area of distribution and chemical composition. The intoxication case from Bremen, however, indicates that this species is psychoactive (see Figure 28). In 1985, I found two fruiting bodies in a pasture, whose dried weight contained 0.03 - 0.05% psilocybin, as well as serotonin. All of the mushrooms' features, such as wrinkled, fleshcolored caps, corresponded to descriptions of *Panaeolus retirugis*.

Based on his analyses, Stijve concluded that the dried fruiting bodies of *Panaeolus subbalteatus* contain about 0.1% psilocybin, regardless of location, as well as a tiny amount of baeocystin. Still, accounts of intoxications with consistently potent psychoactive effects would seem to provide evidence against such small amounts of alkaloids in *Panaeolus subbalteatus*. Indeed, dried mushrooms from the Pacific Northwest region of the United States have been reported to contain 0.16% - 0.65% psilocybin. Moreover, the first analyses of the species in North America (1959) led to the isolation of a water-soluble indole compound which is now generally thought to be baeocystin. My own analyses of mycelia and 19 fruiting bodies from the Heringsdorf location indicated levels of psilocybin that are fully compatible with the data from the United States:

Table 4
Ingredients Found in Mycelia and Fruiting Bodies of *Panaeolus subbalteatus* (% of Dried Material)

Ingredient	Mycelia	Fruiting Bodies
Psilocybin	0.07	0.08(stem)-0.70
Psilocyn	0.00	0.00
Baeocystin	0.00	0.05(stem)-0.46
Serotonin	0.10	0.08-0.30
Urea	0.00	1.80-2.30(cap)

Table 4 shows that the nature and relative amounts of the substances found are different in the fruiting bodies compared to the base mycelium, which was tested here for the first time.

As far as active ingredients are concerned, levels of urea are trivial. The substance does, however, have some significance in terms of chemo-taxonomy. Among species discussed here, urea is present only in *Panaeolus* and *Pluteus* species. Urea was detected "incidentally" during thin-layer chromatography testing intended to discover the presence of indole compounds. Stijve has collected and tested samples of *Panaeolus foenisecii* from eight countries across three continents (namely, America, Europe and Australia), but has consistently failed to find psilocybin in addition to 5-substituted indole compounds. My own analyses of 100 mushrooms from a wide variety of locations across Germany also failed to confirm the presence of this alkaloid and its derivatives. While the local European species that are discussed here also tend to occur on other continents (*Panaeolus subbalteatus*, for example, grows in Hawaii), there are tropical varieties of this genus which are highly psychoactive as well. Given the best possible climate conditions, these species may fruit adventively in Europe for short periods of time.

Panaeolus cyanescens is the most well-known representative of these species (see Figure 29). Like other tropical *Panaeolus* and *Psilocybe* species, *Panaeolus cyanescens* exhibits a strong blue staining reaction. The large number of existing synonyms for the species, as presented by Gerhardt (see Figure 31), again indicates substantial taxonomic confusion, as well as insufficient communication and exchange of information.

Panaeolus Experiences

Sometimes it is difficult to avoid the conclusion that many prominent mycologists are only too willing to disregard existing research results in order to attach their names to definitions of "new" species. Singer lists *Panaeolus cyanescens* separate from *Panaeolus* as belonging to the genus *Copelandia*, along with other species. Nowadays, this classification is becoming increasingly unpopular among mycologists, and many of them do not accept it. *Panaeolus cyanescens* is responsible for a number of remarkable intoxications which occurred on August 19, 1965 in Menton, located on the French Mediterranean Coast. The mushroom spontaneously appeared on compost which consisted of straw and decayed horse dung. The compost was intended to improve lawn quality. It should be noted that the horse dung came from a race track used by horses from tropical countries. Under these circumstances, it is quite likely that the species responsible for the intoxications was imported to the location from another country. On one occasion, in the early 1970s, *Panaeolus cyanescens* was found at the Budapest Fairgrounds next to the pavilions from Thailand and Vietnam!

About the course of the intoxications:

> *A woman and her two children ate a meal consisting of only about 60 g (2.1 ozs.) of the mushrooms. Within less than fifteen minutes after ingestion, she began to feel weak, followed by visual disturbances and marked dilation of the pupils. About one hour after the meal she developed dizzy spells that came and went in waves. Increasingly, all colors in her immediate surroundings coalesced into shades of green. The hallucinations were fearsome; the heads of monsters became visible and a wall opened up into an abyss. There was a succession of human figure with animal heads. The next day, everything was back to normal. The oldest child (age 14) also saw her parents' hair color turn green, had dilated pupils and watched geometric shapes appear on the wall. The youngest child (age 11) experienced cramps and lost consciousness.*

In 1960, Singer and Guzman suggested that *Panaeolus cyanescens* might contain psilocybin, because of the intense blue staining they had observed. It wasn't until after the intoxications in Menton had been publicized, that a research team working with A. Hofmann detected 0.2% of psilocybin in the mushrooms. Considering the powerful effects, however, this concentration appears to be too low to cause such impressive reactions. Later on, Sandoz Laboratories reported the level of psilocybin in dried samples as 0.8%, along with 1.2% psilocin. The level of psilocin, however, may have been falsely elevated by the presence of serotonin and its derivates in the mushroom sample that was being tested.

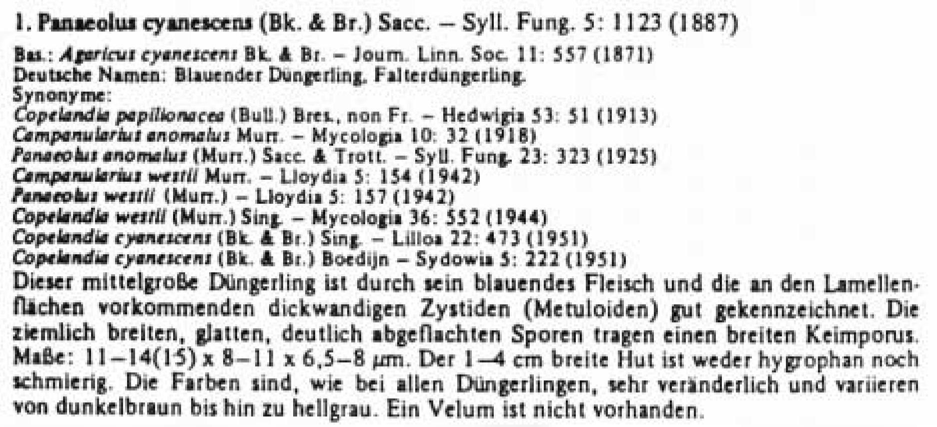
According to Stijve, a mushroom sample collected by J.W. Allen in Thailand contained 0.4% - 1.05% of psilocin, with only trace amounts of psilocybin; serotonin was present in large amounts, comparable to concentrations found in all *Panaeolus* species.

Apparently, *Panaeolus cyanescens* produces more psilocin than psilocybin. Still, I was able to detect 0.4% of psilocybin in mycelia cultivated on malt agar, with no other indole compounds present.

Discussion of the *Panaeolus* species would remain incomplete without pointing out that those subjectively terrifying psychoses reported in 1965 cannot be attributed to a specific mushroom ingredient, but were likely precipitated by the circumstances (set and setting) surrounding the incident. The effects described by J. Allen in Hawaii after eating 20 specimens paint a different picture altogether:

> *With radio music playing softly in the dark, euphoria began to come on in waves. After 20 minutes, visions became so intense that I tried to close my eyes. Whenever I did close my eyes, my eyelids felt as if they were being sprayed from the outside. Colors were sharp and clear, but I always quickly opened my eyes again. Colors were dancing like laser beams to the rhythm of the music. The stars in the sky assembled in clusters that reached all the way into my soul. I was a little scared at the idea that the ocean water might rush up all the way into our hut. Other than that, feelings of euphoria were overwhelming. At times, I was overcome by fits of laughter. That night, I slept like "a prince ". The following morning I gathered up my belongings and had to walk back across the pasture where I had collected the mushrooms the day before. I noticed a lot of new mushrooms that had grown during the previous night's rainfall. By way of a lingering after effect I felt that the mushrooms were sending me a message: "Don't forget us, come back, if you can".*

It is important to keep in mind that more comprehensive studies on taxonomy and biochemical composition are needed in order to fully understand the *Panaeolus* species. Perhaps A. Weil's suggestion that *Panaeolus subbalteatus* from America's Pacific Northwest induces comparatively stronger somatic effects than the *Psilocybe* species can be investigated chemically as well as toxicologically, in order to reject or support this hypothesis.



1. Panaeolus cyanescens (Bk. & Br.) Sacc. — Syll. Fung. 5: 1123 (1887)

Bas.: *Agaricus cyanescens* Bk. & Br. – Journ. Linn. Soc. 11: 557 (1871)
Deutsche Namen: Blauender Düngerling, Falterdüngerling.
Synonyme:
Copelandia papilionacea (Bull.) Bres., non Fr. – Hedwigia 53: 51 (1913)
Campanularius anomalus Murr. – Mycologia 10: 32 (1918)
Panaeolus anomalus (Murr.) Sacc. & Trott. – Syll. Fung. 23: 323 (1925)
Campanularius westii Murr. – Lloydia 5: 154 (1942)
Panaeolus westii (Murr.) – Lloydia 5: 157 (1942)
Copelandia westii (Murr.) Sing. – Mycologia 36: 552 (1944)
Copelandia cyanescens (Bk. & Br.) Sing. – Lilloa 22: 473 (1951)
Copelandia cyanescens (Bk. & Br.) Boedijn – Sydowia 5: 222 (1951)

Dieser mittelgroße Düngerling ist durch sein blauendes Fleisch und die an den Lamellenflächen vorkommenden dickwandigen Zystiden (Metuloiden) gut gekennzeichnet. Die ziemlich breiten, glatten, deutlich abgeflachten Sporen tragen einen breiten Keimporus. Maße: 11–14(15) x 8–11 x 6,5–8 µm. Der 1–4 cm breite Hut ist weder hygrophan noch schmierig. Die Farben sind, wie bei allen Düngerlingen, sehr veränderlich und variieren von dunkelbraun bis hin zu hellgrau. Ein Velum ist nicht vorhanden.

Figure 31 - Synonyms for ***Panaeolus cyanescens*** (according to Gerhardt).

3.4 - *Inocybe aeruginascens*: Fast-Spreading New Arrivals

On June 15, 1965, I. Ferencz discovered fruiting bodies known as "fibrehead mushrooms" in Osca, Hungary, county of Pest. The mushrooms' characteristics did not match those of any known species of the genus *Inocybe*, as described in the literature. That same year, as well as on several occasions later on, Ferencz and other mycologists found large numbers of mushrooms of the same species growing in different locations. Eventually, in 1968, these mushrooms were described as a new species named *Inocybe aeruginascens* Babos (see Figure 33, p. 47).

Strange Distribution Patterns in Hungary and Germany

In 1985, a few mycologists who specialized in the study of the genus *Inocybe* found fibreheads with greenish discolorations in 17 locations (46 specimens) across Hungary. In her 1983 article, Babos noted that *Inocybe aeruginascens* had become the most common mushroom of the Lower Valley's sandy areas around the Hungarian capital city of Budapest. The species is known to fruit across these areas, singly or in gregarious clusters on the sandy soil of the poplar forests, or in mixed forests that include poplars. They have also been found on meadows near poplar trees. The mushrooms are loyal to the location and grow there every year, climate conditions permitting.

In 1975, Kaspar collected the *Inocybe* species in Berlin (Köpenick District) as well. More detailed studies revealed that the mushrooms had previously been misidentified. As early as 1965, fruiting bodies of the species were found in the arboretum at Berlin (Baumschulenweg District). The species had been noted "in passing" by other mycologists with little interest in the mushrooms. Many species (about 160) of the large European *Inocybe* genus cannot be easily differentiated from each other, and therefore attract little interest from expert mycologists. The species are part of a large group of mushrooms that are nicknamed "LBMs" (Little Brown Mushrooms) in the American literature and as such they often entail considerable taxonomic problems. Other examples of mushrooms in this group are the *Panaeolus* species as well as those of the genus *Psilocybe*.

Whenever a "new mushroom" appears spontaneously, the question of its origin has to be addressed. Herink, the Czech mycologist, maintains that he had already discovered the species during the 1930s. He reportedly deposited samples in a herbarium, but the mushrooms have never been clearly identified as *Inocybe aeruginascens* on the basis of biochemical analyses. As fruiting bodies of the *Inocybe aeruginascens* were found simultaneously in Hungary and Germany, the direction of the species' geographical migration could not be determined. It is possible that the species was initially confined to a very small area and only began to attract attention after it had migrated into new habitats. We can only speculate about the possibility of mutations that may have evolved from known species over a relatively short period of time.

Finally, during the 1980s, a few fruiting bodies were collected at locations in Holland (1980) and the Rhone Valley (Wallis Canton) of Switzerland (1984).

In 1983, the species immediately attracted the attention of biochemists and clinicians, after G. Drewitz described mysterious psychotropic intoxications caused by these mushrooms in the city and district of Potsdam, Germany, during June and July, 1980. The observed range of effects was sensational for mushrooms of the *Inocybe* genus, because many of its species induce typical muscarine poisoning symptoms. Muscarine causes parasympathetico-mimetic symptoms, such as pupil contraction (miosis), increased salivation and saliva production. Muscarine has been identified in at least 40 species of the *Inocybe* genus. The first reports about deaths following ingestion of the potent muscarine-containing *Inocybe patouillardii* Bres. date back to the early 20th century.

Identification Errors

Below is a more detailed description of the effects of *Inocybe aeruginascens*:

> *On June 30, 1980 a teenager collected the mushrooms near Potsdam and misidentified them as fairy ring mushrooms (Marasmius oreades (Bolt. & Fr.) Fr.), a species known as a choice table mushroom. At home, the teenager's father sauteed the mushrooms in margarine, and they were subsequently eaten by both of them. The son ate only about one-third of the cooked mushrooms.*
>
> *About 35 to 45 minutes after the meal, both father and son began to experience initial symptoms. The son mainly reported colorful illusions and hallucinations. The woven pattern of his white handkerchief suddenly appeared as shining stripes of crimson red. With his eyes closed, he saw magically illuminated, abstract structures. He noticed his own state of foolish silliness that occurred for apparently no reason at all. Following his father's instructions, he soon found himself outside, in the pouring rain, running back to a near-by railroad embankment, still laughing and giggling, in order to gather more of the mushrooms that had poisoned him.*
>
> *The father's symptoms initially included yawning and a burning sensation of the face, as well as itching at the hairline and fatigue. He then experienced increasing numbness (paraesthesia) of the left half of his face and his left arm. Later on, these symptoms spread to the right half of his body. Fully conscious, he also noticed motor disturbances that disrupted his language ability. His psyche was increasingly dominated by images of depersonalization: For the duration of the experience he felt that he "was standing beside himself as an observer", while his voice sounded very strange to him.*

The second case of intoxication in Potsdam occurred on July 13, 1980:

> *Seventy-five minutes after ingestion of fibrehead mushrooms with greenish discolorations (Inocvbe aeruginascens), the woman began to experience hot flashes, nausea without vomiting, strongly dilated pupils, along with a marked sense of intoxication that she described as "mostly amusing". Spacial illusions were experienced in combination with striking feelings of weightlessness, distances appeared to be magnified. After several hours, these symptoms gradually faded without lasting consequences; only the dilation of the pupils persisted well into the next day.*

Based on these cases, Drewitz proposed that the mushrooms contain psilocybin or similar substances, a hypothesis that was later confirmed (see Tables 6 and 7, p. 49).

More cases of intoxications were reported in the years that followed and earlier cases could also be traced to this mushroom species. In each of these cases, the mushrooms were misidentified as fairy ring mushrooms.

Table 5
Accidental Intoxications with *Inocybe aeruginascens* in Eastern Germany

Year	# of People	Location
1977	3	Hohen-Neuendorf
1980	2	Teltow
1980	1	Potsdam
1984	4	Oranienburg
1984	2	Magdeburg
1985	3	Woltersdorf
1986	7	Potsdam

In all cases, the symptoms subsided after several hours, with no lasting side effects. A psychiatrist surely would have found these situations interesting - especially the last case involving an extended family - and would most likely have welcomed the opportunity to study the psychodynamics and social interactions during the period of collective intoxication.

In 1983, Babos reported another case of unintentional ingestion of *Inocybe aeruginascens* in Budapest, which had occurred on July 1, 1970. In this case, symptoms included subjective feelings of decreasing gravity, colorful hallucinations, spacial illusions and nausea without vomiting.

Flights of the Soul

In this context, the following account is of interest; it details the experience of a mycologist who took 2.4 g of dried mushrooms in the course of a test experiment:

> *The mushrooms tasted like ordinary table mushrooms. While reclining in a state of relaxation about 30 minutes later, a very comfortable feeling of loss of gravity set in, with no other somatic effects. Abstract hallucinations developed slowly, in the form of bursting colors and lights. Once a state of complete loss of gravity was attained, it was followed by a very vivid sensation of the soul in flight, coupled with feelings of euphoria. When looking out the window into the dark night of a forest landscape, visions of strange patterns and formations occurred, which were deeply impressive and seemed to impart an inkling of eternity. At the end of four hours, the effects had dissipated without dysphoria or any type of somatic side effect.*
>
> *A control experiment for comparison purposes was performed using 0.8 g of dried Psilocybe semilanceata. The onset of symptoms was much more sudden, including a heavy flow of tears, so that there was an initial phase of anxiety. Only in a later phase of the experience was it possible to perceive ornaments in the form of "underwater streamers", and to appreciate the aesthetically enhanced nature of these visions.*

The regular pattern of involuntary intoxications is a good indicator for the large scope of expansion of *Inocybe aeruginascens* into new habitats during the 1980s. For example, at the time of the initial intoxications - when the species was still restricted to a few easily quantifiable collections - the mushrooms had spread from Potsdam to the location known in 1982, and from there moved on to several other locations in the vicinity, where more than 150 mushrooms were found (see Figure 34).

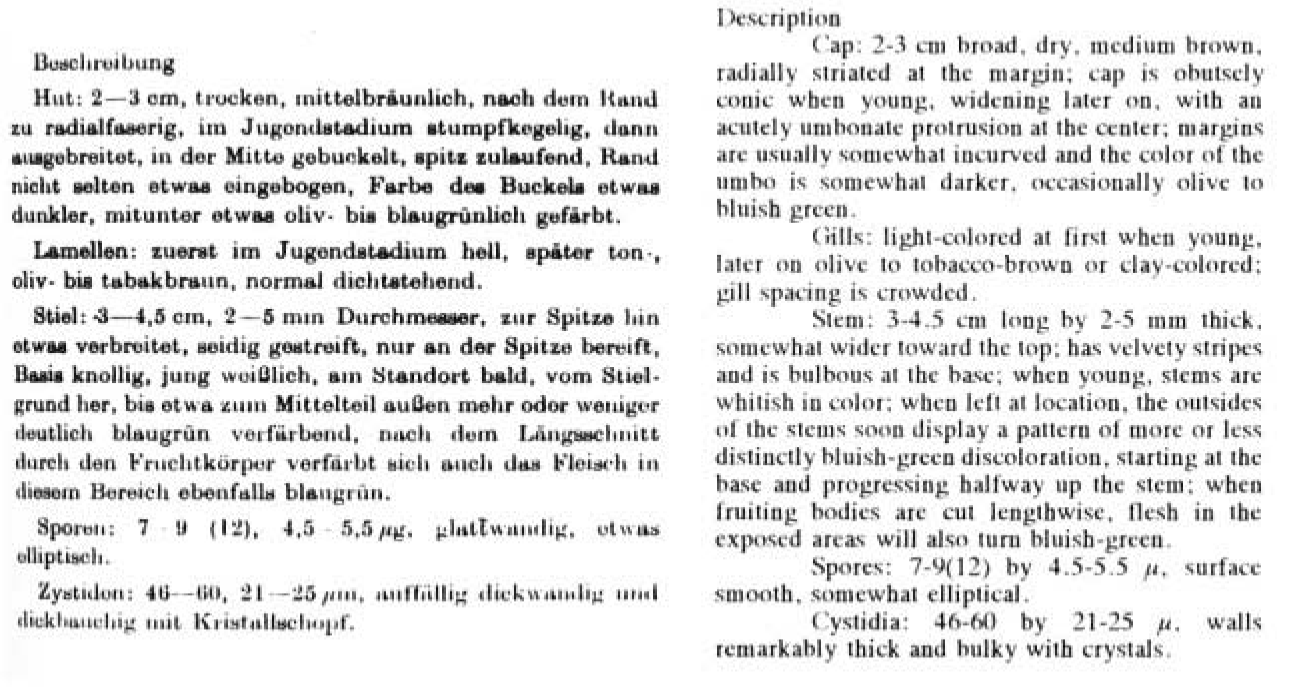
Symbiosis With Trees

Starting in late May 1984, fruiting bodies of the species could be found in abundance at countless new locations across the Brandenburg region of Germany. They tend to grow near the roots of different deciduous trees (*Populus, Tilia, Quercus, Betul*a), on lawns in parks and gardens, at the edges of trails and in the paved margin areas of tree-lined sidewalks (where they may even grow on bare, sandy soil) as well as amongst the greenery of residential areas in the suburbs and communities in and around Berlin.

Herein lies the most marked difference between *Inocybe aeruginascens* and other European psychotropic mushroom species: *Inocybe aeruginascens* grows only in areas of human development. Their prime locations are in the middle of villages and towns, where they grow locally much like other *Inocybe* species. They may temporarily produce mass quantities of fruiting bodies, in those locations that are typical habitats for the edible varieties of the fairy ring mushroom.

So far, the most abundant crop of fruiting bodies was observed in 1987, due to very wet weather conditions, which allowed the mushrooms to thrive. The following years were comparatively dry and the species hardly fruited at all. It wasn't until 1990 that a few mushrooms re-emerged at the classic location in Potsdam. Despite 1989 having been a bad year for mushrooms, it was the year when *Inocybe aeruginascens* was found for the first time at four locations in and around Rostock, a city located on the Eastern German coast, which is famous for its wet climate. Finding the mushrooms at these locations is evidence for a much wider expansion of the species. In coming years, we should expect the species to further migrate into areas with sandy soil.

The *Inocybe* species are mycorrhizal mushrooms, that is, in contrast to other psilocybin-containing species, they require a symbiosis with certain types of wood in order to fruit. Fruiting occurs at the time of greatest biochemical activity of the symbiotic partner trees. Following periods of extended rainfall, *Inocybe aeruginascens* grows in the trees' root areas from late May until October. The mushrooms are especially common in May and June, a time period during which *Inocybe aeruginascens* is easily differentiated from other species of fibreheads, as long as one pays close attention to locations, the characteristic greenish to bluish discoloration (e.g. if the mushrooms are stored overnight, especially in the refrigerator) and the description shown below (see Figure 32).



Beschreibung

Hut: 2—3 cm, trocken, mittelbräunlich, nach dem Rand zu radialfaserig, im Jugendstadium stumpfkegelig, dann ausgebreitet, in der Mitte gebuckelt, spitz zulaufend, Rand nicht selten etwas eingebogen, Farbe des Buckels etwas dunkler, mitunter etwas oliv- bis blaugrünlich gefärbt.

Lamellen: zuerst im Jugendstadium hell, später ton-, oliv- bis tabakbraun, normal dichtstehend.

Stiel: 3—4,5 cm, 2—5 mm Durchmesser, zur Spitze hin etwas verbreitet, seidig gestreift, nur an der Spitze bereift, Basis knollig, jung weißlich, am Standort bald, vom Stielgrund her, bis etwa zum Mittelteil außen mehr oder weniger deutlich blaugrün verfärbend, nach dem Längsschnitt durch den Fruchtkörper verfärbt sich auch das Fleisch in diesem Bereich ebenfalls blaugrün.

Sporen: 7—9 (12), 4,5—5,5 μg, glattwandig, etwas elliptisch.

Zystiden: 46—60, 21—25 μm, auffällig dickwandig und dickbauchig mit Kristallschopf.

Description

Cap: 2-3 cm broad, dry, medium brown, radially striated at the margin; cap is obutsely conic when young, widening later on, with an acutely umbonate protrusion at the center; margins are usually somewhat incurved and the color of the umbo is somewhat darker, occasionally olive to bluish green.

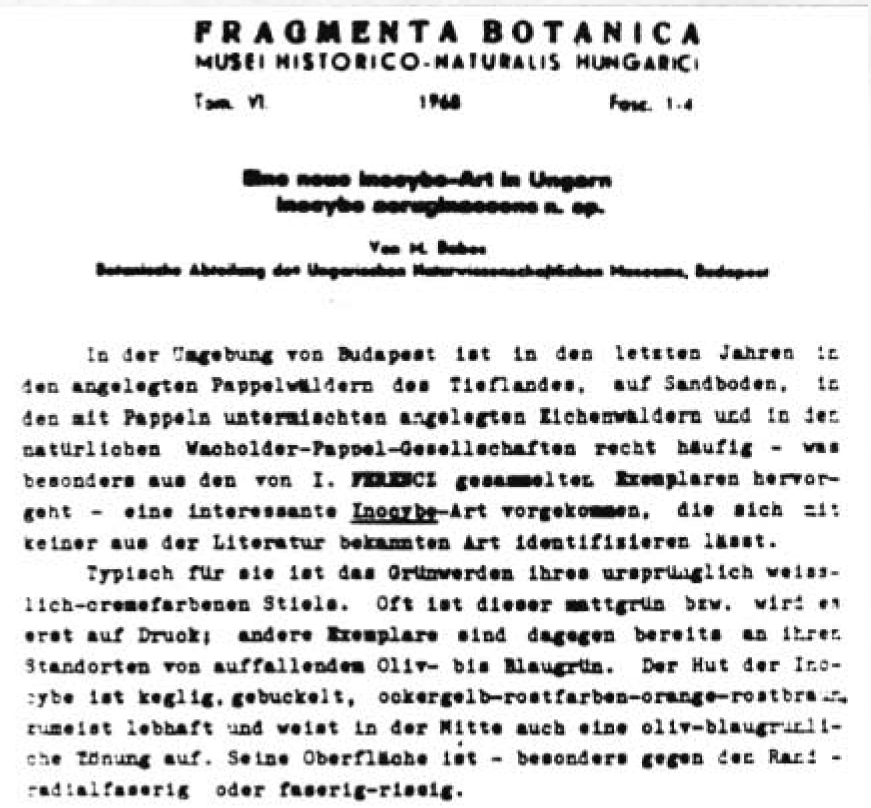
Gills: light-colored at first when young, later on olive to tobacco-brown or clay-colored; gill spacing is crowded.

Stem: 3-4.5 cm long by 2-5 mm thick, somewhat wider toward the top; has velvety stripes and is bulbous at the base; when young, stems are whitish in color; when left at location, the outsides of the stems soon display a pattern of more or less distinctly bluish-green discoloration, starting at the base and progressing halfway up the stem; when fruiting bodies are cut lengthwise, flesh in the exposed areas will also turn bluish-green.

Spores: 7-9(12) by 4.5-5.5 μ, surface smooth, somewhat elliptical.

Cystidia: 46-60 by 21-25 μ, walls remarkably thick and bulky with crystals.

Figure 32 - Description of ***Inocybe aeruginascens*** (Germany, 1986) with English translation at right.



FRAGMENTA BOTANICA
MUSEI HISTORICO-NATURALIS HUNGARICI
Tom. VI. 1968 Fasc. 1-4

Eine neue Inocybe-Art in Ungarn
Inocybe aeruginascens n. sp.

Von M. Babos
Botanische Abteilung des Ungarischen Naturwissenschaftlichen Museums, Budapest

In der Umgebung von Budapest ist in den letzten Jahren in den angelegten Pappelwäldern des Tieflandes, auf Sandboden, in den mit Pappeln untermischten angelegten Eichenwäldern und in den natürlichen Wacholder-Pappel-Gesellschaften recht häufig - was besonders aus den von I. FERENCI gesammelten Exemplaren hervorgeht - eine interessante Inocybe-Art vorgekommen, die sich mit keiner aus der Literatur bekannten Art identifizieren lässt.

Typisch für sie ist das Grünwerden ihres ursprünglich weisslich-cremefarbenen Stiels. Oft ist dieser mattgrün bzw. wird es erst auf Druck; andere Exemplare sind dagegen bereits an ihren Standorten von auffallendem Oliv- bis Blaugrün. Der Hut der Inocybe ist keglig, gebuckelt, ockergelb-rostfarben-orange-rostbraun, zumeist lebhaft und weist in der Mitte auch eine oliv-blaugrünliche Tönung auf. Seine Oberfläche ist - besonders gegen den Rand - radialfaserig oder faserig-rissig.

Figure 33 - First description of ***Inocybe aeruginascens*** in the mycological literature (M. Babos, 1968).

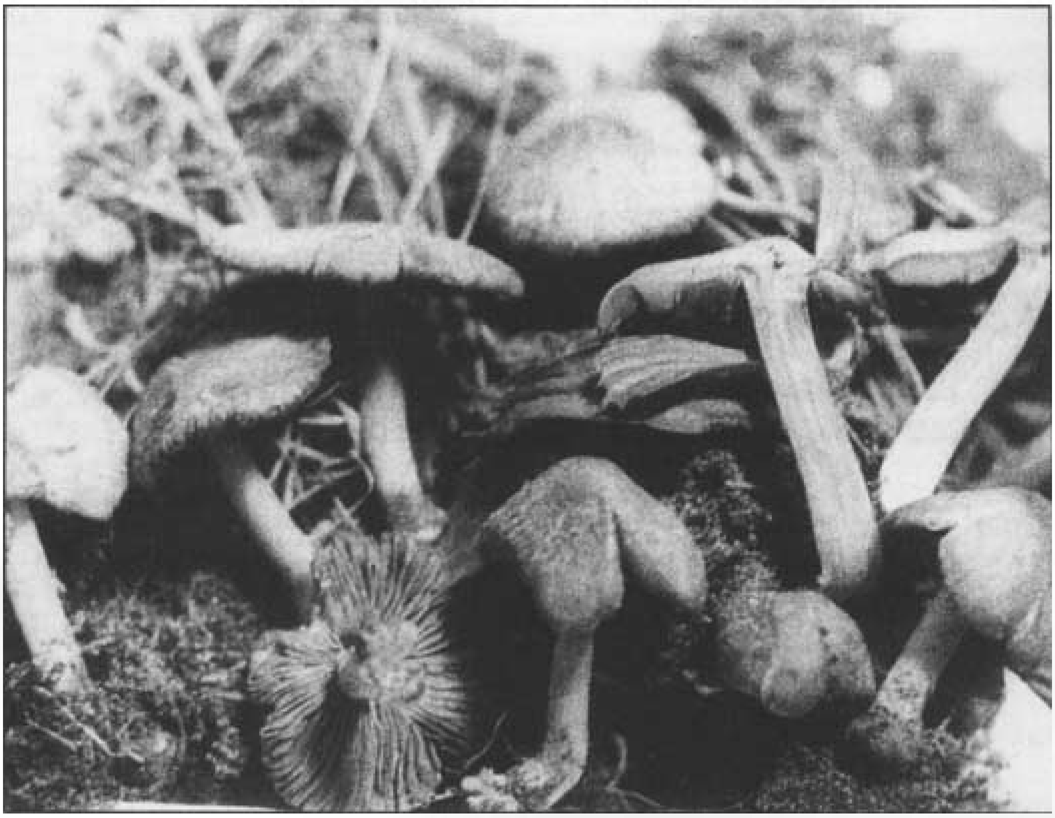


Figure 34 - ***Inocybe aeruginascens*** fruiting bodies from Potsdam, Eastern Germany.

Unlike species of thin-fleshed *Psilocybe* mushrooms that do not fruit until fall, *Inocybe aeruginascens* frequently suffers from fly larvae infestations, especially in older colonies. The resulting lesions are injured areas that turn greenish-blue. It must be noted, however, that of all species introduced here, *Inocybe aeruginascens* is most easily misidentified by laypersons, as it is of the same genus as the potentially lethal species that produce muscarine.

Drewitz's speculation that *Inocybe aeruginascens* contains psilocybin was supported by results from my own investigations in 1984. Extracts of more than 100 mushrooms collected in Hungary and Germany from 1967 to 1990 were examined. Quantitative analyses revealed that the fruiting bodies contained a fairly constant amount of psilocybin each, as well as some baeocystin. These results were first reported in February, 1985. Later that year, the presence of psilocybin in *Inocybe aeruginascens* was confirmed by research teams from the former West Berlin, Regensburg (Germany) and Switzerland. Known cases of intoxication seemed to indicate that the fruiting bodies contained small amounts of muscarine. But among all the samples that were tested - at all stages of development and from widely different collections - not one specimen contained even trace amounts of muscarine.

In collaboration with colleagues from Czechoslovakia, we were able to confirm that the average alkaloid content does not vary much, a finding based on analyses of extracts from several mushrooms. Moreover, the alkaloid content of fruiting bodies stored for prolonged periods declined only slightly over time:

Table 6

Psilocybin Content of *Inocybe aeruginascens* from Various Locations (% of Dried Samples)

Location	Year Found	Year Analyzed	Psilocvbin
Potsdam	1984	1984	0.38
Potsdam	1983	1984	0.34
Potsdam	1982	1984	0.33
Berlin	1975	1985	0.11
Hungary	1967	1985	0.22

Psilocybin levels in *Inocybe aeruginascens* are comparable to those found in *Psilocybe mexicana* Heim. Moreover, *Inocybe aeruginascens* contain traces amounts of psilocin at most. Baeocystin, on the other hand, is accumulated at levels comparable to those of psilocybin. The alkaloid content of the *Inocybe* species differs from those found in the *Psilocybe* species, which contain three to five times more psilocybin than baeocystin. The variation of alkaloid content across different samples of fruiting bodies is illustrated in Table 7, which shows the results from analyses of mushrooms collected at a location in Caputh near Potsdam on June 8, 1986 (see Figures 32 and 34).

Table 7
Psilocybin and Baeocystin Content in Single *Inocybe aeruginascens* Fruiting Bodies (% of Dry Weight)

Mushroom	Dry Weight (mg)	Psilocybin	Baeocystin
1	0.110	0.43	0.15
2	0.118	0.26	0.24
3	0.220	0.23	0.22
4	0.221	0.50	0.25
5	0.298	0.16	0.20

In addition, it should be noted that results from these analyses of mushroom extracts indicated the presence of a previously unknown alkaloid, which I have named *aeruginascin*. The molecular structure of this substance must be similar to those of psilocybin and baeocystin. It is a compound that is soluble only in polar solvents, such as water, methanol and acetic acid. The levels of concentration of *aeruginascin* found in the fruiting bodies is comparable to those of the other two alkaloids. The compound is characteristic of the *Inocybe* species, so that the analytical results of mushrooms extracts using thin-layer chromatography constitute a kind of fingerprint identification of *Inocybe aeruginascens*.

Of course, there is the question whether this substance contributes to the psychoactive effects of *Inocybe aeruginascens*. It is remarkable that all cases of involuntary intoxication induced a feeling of euphoria, despite a psychological state of mind likely to create extremely unfavorable internal conditions ("set") for having a "positive experience" (i.e. knowledge of being poisoned by mushrooms with unknown and potentially fatal consequences). In addition, these cases of intoxications happened in the course of pursuing normal, everyday activities, including appointments and other interferences ("setting") which should have precipitated a much more negative type of experience. Future research must focus first on the discovery of the molecular structure of *aeruginascin*, as well as its synthesis. Subsequent studies should investigate the potentially mood-altering influence of this substance in terms of the mushroom's psychoactive effects as a whole. Moreover, we cannot exclude the possibility that ingestion of the mushrooms may cause a slow release of alkaloids from the organic matrix, followed by their gradual resorption, a process suggested by the effects of the mycologist's test experiment described above. In the meantime, the presence of psilocybin along with baeocystin has also been confirmed in the following *Inocybe* species:

Inocybe corydalina Quel.
Inocybe haemacta Berk. & Br.
Inocybe tricolor Kuhner
Inocybe coelestium Kuyper

These species, however, are not significant contributors in terms of involuntary intoxications, because, for the most part, these *Inocybe* species are extremely rare and grow almost exclusively in forests. Also, their psilocybin levels were lower than those found in *Inocybe aeruginascens*.

Among these species, *Inocybe corydalina* is the most common. An analysis revealed a psilocybin content of only 0.011% - 0.1%, a concentration so low, that this species would become clinically relevant only if large amounts of the mushrooms were eaten.

As part of my own experiments, I also detected psilocybin in *Inocybe calamistrata* (Fr.:Fr.) Gill, a species whose lower stem area is blue. Other authors have not succeeded at confirming the presence of psilocybin in this species.

3.5 - *Gymnopilus purpuratus*: Magnificent Mushrooms from South America

Another controversy documented in the literature revolves around the psychoactivity of several species of the genus *Gymnopilus*.

More than 50 years ago, in October 1942, a remarkable case of intoxication occurred in Cleveland, Ohio, which was attributed to *Pholiota spectabilis*. Today, these mushrooms have been identified as *Gymnopilus spectabilis* (Fr.) A.H. Smith (USA). In Europe, they are also Known as *Gymnopilus junonius* (Fr.) Orton.

> *A woman had been out for a walk in the woods one afternoon and had taken a few nibbles from a mushroom that she found, feeling confident that she could distinguish the edible from the poisonous ones. As soon as she lay down, she began to experience the most glorious visions of color and sounds of music, but with no feelings of discomfort whatsoever. A friend who was with her felt that a doctor should be called immediately. When she consulted me about her symptoms, I told her that certain mushrooms are known to cause the symptoms she suffered. I added that these mushrooms were not classified as poisonous, nor did the effects last very long. Called that same evening and said that the hallucinations had soon passed and that she was feeling perfectly normal again. She added that if this was the way one was supposed to die of mushroom poisoning, she was all for it.*

Another case of poisoning was chronicled in Harvard, Massachusetts:

> *On September 9, 1966, at about 9 a.m., a 56-year-old retired mechanical engineer of Harvard, Massachusetts, picked a bunch of mushrooms clustered by the side of the road in front of his house. Under the mistaken impression that they were honey mushrooms (Armillaria mellea an edible species) he tasted the fresh flesh and found them to be slightly bitter. However, he took them home, where his wife washed them and fried them in butter. He ate two or three caps around noon and within 15 minutes began to feel disconnected and "woozy", head felt numb and his vision was blurred. The room seemed smaller, and the walls closer than usual. Objects were shimmering, and appeared yellow with dark areas in the center. The trees and grass were a vivid green, with spots of radiant purple. These sensations were not unpleasant. Everything seemed to be unnaturally colored, resembling the image of a color TV. Even though he was unable to collect his thoughts, his mind felt sharp and clear: he asked himself questions and immediately knew the answers. By contrast, after having put down a book, he was unable to find it again. After a few hours all three of the involuntary participants had recovered and were able to give a coherent account of their experience.*

In this case, the mushrooms involved were also identified as *Pholiota spectabilis*. This identification is questionable, however, because the species is generally described as having an extremely bitter taste. It was determined that there are significantly more species of the genus *Gymnopilus* in North America (73) than there are in Europe (15).

Mushrooms 24 Inches Tall!

Even though *Gymnopilus junonius* is one of the largest-sized species of mushrooms (with stems that have been observed to grow up to 24 inches [60 cm] tall), there are no known European cases of intoxications caused by *Gymnopilus* species. The extremely bitter taste typical of some *Gymnopilus* species is an effective deterrent to their ingestion as table mushrooms, anyway

However, the cases of intoxication in the U.S. prompted Hatfield and his collaborators to perform phytochemical testing on some of these species. From 1968 to 1971 this group of investigators reported that eight species, including *Gymnopilus junonius* contained inactive styrylpyrones, such as bis-noryangonin. In the wake of yet another case of unintentional intoxication with *Gymnopilus validipes* in the U.S., the same research team was able to confirm that this species contained psilocybin (0.12%). They also found the alkaloid in three other species, including *Gymnopilus spectabilis*.

Still, similar analyses of European *Gymnopilus* species continued to yield negative results.

It was only through a set of strange circumstances that the presence of psilocybin and its derivatives was finally confirmed in European mushroom species of the genus *Gymnopilus*.

As far back as May 1887, a new species of mushroom was found growing on a tree fern trunk in the botanical gardens at Kew, England (also see p. 30, bottom right). The discovery eventually led to the publication of these mushrooms as a new species named *Flammula purpurata* Cooke & Massee. In this context, we must credit Mordecai Cooke (1825-1914), a mycologist of outstanding competence and expertise, who studied a vast number of mushrooms species, including *Psilocybe semilanceata*. He was the first to formulate a hypothesis about the nature of the bluing phenomenon and to point out its physiological significance (also see p. 16, bottom right). He discovered *Inocybe haemacta* as well as several *Panaeolus* species and classified the *Flammula* species mentioned above. Remarkably, one of his first publications was a book of popular folk tales entitled "*The Seven Sisters of Sleep*" (1860), which just happened to be an interdisciplinary investigation of narcotic plants. Did he himself, perhaps, sample one of the psychotropic mushroom species? Most likely, we will never know the answer to this question. Eventually, the *Flammula* species came to be recognized as being native to Australia and South America (Chile), where the mushrooms fruit on dead tree trunks during the month of May. Later on the mushroom's name was changed to *Gymnopilus purpuratus* (Cooke & Massee) Sing.

Mushrooms on Compost Mixture of Wood Chips and Pig Manure

In 1983, a conspicuous mushroom was observed growing on discarded bark and wood chips near a particle board factory in Ribnitz-Damgarten on the Eastern German seaboard. The mushroom was initially classified as *Tricholomopsis rutilans* (Schaeff.:Fr.) Sing. However, this magnificent and beautiful mushroom was found to have spore dust colored orange to rusty brown, along with a well-formed, bright yellow cortina. It also turned blue in reaction to pressure and with age. Closer study revealed that the specimen was actually of the species *Gymnopilus purpuratus*, a mushroom that, after a hundred years, had once again been imported into Europe. The microclimate essential for the mushroom's growth had been created by mixing liquid pig manure with the discarded wood chips. A powerful composting process results from pouring the liquid manure onto heaps that are up to 20 yards long and several yards tall.The process is designed to eliminate both types of refuse. Measurements inside the heaps revealed temperatures of about 176° Fahrenheit. Consequently, the *Gymnopilus* species were able to thrive on the top layers of the heaps, along with other species from Asian and South American countries with warm climates.

There is, of course, the question of just how the *Gymnopilus* species got to Europe in the first place. In the late 1970s, large amounts of feed grain were imported from Argentina. Thus, it appears likely that some mushroom spores may have stuck to the grain from where they passed unharmed through the pigs' digestive systems and went on to colonize the compost heaps.

Even though the compost heaps are plowed at least twice a year and shipped as fertilizer to surrounding fields after about two years of storage, the mushrooms continue to grow on wood piles in new locations whenever its spores have reproduced (see Figure 30, p. 40). However, in the wake of changes in economic conditions and growing ecological awareness in Eastern Germany, it is likely that this composting process will soon be discontinued so that this mushroom species may disappear in Europe once again.

The following description characterizes the *Gymnopilus* species that does not have a bitter taste:

> *Cap*: 15-42 mm broad, occasionally larger sizes up to 20 cm in diameter. Flesh thin, broadly convex without an umbo. Evenly covered with pointy scales, purplish to ruby on yellow background, dry. Margin inrolled at first, incurved later, occasional blue stains.
>
> *Gills*: Close, golden yellow at first, rusty yellow later on due to maturation of spores, edges concolorous with lamellae and bald.
>
> *Stem*: Not hollow, 6-10 mm x 30-80 mm, very rarely up to 15 cm tall, cylindrical to slightly club-shaped, coarse fibrils, striated, lower stem area and base bruise grayish-blue to Greenish when injured and with age, found alone or in clusters of up to 22 mushrooms.

Cortina: Sulphur yellow, almost appendiculate along margin, fibrous at the apex without forming a true annulus, disappears with age.

Basidia: Approximately 35 µ long, club.

By 1969, Singer had noted that based on analyses performed by Cassels in Chile, the mushroom contained an indole derivative and that the species may be hallucinogenic because of the bluing reaction. By 1988, reports from Germany also confirmed the presence of psilocybin in mushroom extracts of the same species, as evidenced by the results of thin-layer chromatography testing (qualitative detection only). That same year, my own quantitative analyses of 26 mushrooms also revealed that psilocin and baeocystin were present in all fruiting bodies of the *Gymnopilus* species. So far, no other European species has been found to contain as much psilocin as *Gymnopilus purpuratus*:

Table 8
Alkaloid Content in Two Collections of *Gymnopilus purpuratus*
(% of Dry Weight).

Mushroom	Psilocybin	Psilocyn	Baeocystin
Sample Collected in 1988			
1	0.29	0.28	0.05
2	0.31	0.29	0.04
Sample Collected in 1987			
1	0.32	0.03	0.03
2	0.21	0.02	0.02

Table 8 illustrates the unstable nature of the psilocin molecule: during the one-year storage time until analysis in 1988, much of the sample's psilocin had already decayed.

Alkaloid concentrations were found to be higher in smaller mushrooms, as shown in Table 8. Larger mushrooms contained about 0.1% of both psilocin and psilocybin. I am not aware of any cases of accidental intoxication nor any self experiments involving *Gymnopilus purpuratus*.

Intoxicating Potions of the Yurimagua Indians

In light of the discovery of psilocybin as an active ingredient in a South American *Gymnopilus* species, numerous historic accounts also appear in a different light.

Jesuits of the 17th and early 18th centuries who had travelled to the western Amazon (Peru) reported that the Yurimagua Indians habitually prepared a potently intoxicating potion derived from a tree-dwelling mushroom. The mushrooms appeared on fallen trees as a kind of reddish growth with a spicy taste. The potion was said to be so potent that nobody who swallowed three mouthfuls of the brew was able to resist its effects. The mushroom was considered to be *Psilocybe yungensis* Singer & Smith. However, since *Gymnopilus* species are reddish in color (see description of *Gymnopilus purpuratus*, above) and tend to colonize dense tree trunks, those strange tree-dwelling mushrooms were most likely a *Gymnopilus* species. The *Psilocybe* species, after all, grow almost exclusively on wood sprigs and tree bark debris. On only one exceptional occasion did we discover a specimen of *Psilocybe bohemica* growing on a thoroughly rotted, wet tree trunk (see p. 31, top right). Most likely, the reddish-colored tree-dwelling species was closely related to *Gymnopilus purpuratus*. The discovery of psilocybin in a mushroom of the *Gymnopilus* species marked the first time this substance had ever been found in a member of the family *Cortinariaceae*.

The *Inocybe* species who were found to contain psilocybin later on, are also members of this family. Since the alkaloid had previously been found in *Psilocybe*, *Panaeolus* and *Conocybe* species - which are not closely related to each other - the hypothesis postulating psilocybin's significance as an important chemotaxonomical substance had to be abandoned.

Future research should attempt to verify the presence of psilocybin and its derivatives in other tropical and subtropical *Gymnopilus* species. Taxonomically, the genus has not yet been exhaustively studied, and mushroom lovers may want to watch out for occurrences of *Gymnopilus purpuratus* in certain European locations, such as botanical gardens or herbariums.

3.6 - *Conocybe cyanopus*: Tiny Mushrooms of Remarkable Potency

While studying the magic mushrooms of Mexico during the 1950s, R. Heim described a new species of the genus *Conocybe*.

Conocybe siligineodes Heim was reported to grow up to 8 cm (3.25 in.) tall, a beautiful, reddish brown to orange-colored mushroom that thrived on rotten wood and which was used as a psychotropic species by the Indians as well. However, the species did not appear again in the literature, nor were the chemical composition or the effects of these samples published. Even after decades of field research in Mexico, Guzman was unable to find the species there. Similarly, he did not discover native usage of any kind of *Conocybe* species. Heim's description however, aroused curiosity as to the chemical composition of this species. Approximately 55 European species which existed saprophytically were relegated to a shadow existence in the older literature. Also, the differentiation of these species is very problematic at times. For the most part, the mushrooms are small and fragile, decay quickly and grow mostly in grassy and mossy areas, where they are easily overlooked.

Around 1930, J. Schaffer discovered numerous *Conocybe* species growing in abundance on a fertilized grassy area near Potsdam. Intrigued by the mushrooms' extraordinary variety of forms and colors, he was inspired to undertake the kind of taxonomic classification that is essential to pursuing mushroom research. One species that he found in Potsdam, Berlin as well as in Germany's Harz Mountains showed bluish discolorations at the base of their stems. This "Galera" species was included by Kuhner as *Conocybe cyanopoda* in his 1935 monograph about the genus *Conocybe*. Today, this species is referred to in the literature as *Conocybe cyanopus* (Atk.) Kuhn. This species with a blue base had been previously discovered in the U.S. (Ithaca, NY) in 1918 and was judged by Kuhner to be identical with the European mushrooms.

The following is an adequate description of *Conocybe cyanopus*, because its bluish discoloration is a sufficiently unique attribute to allow differentiation of this species from other European *Conocybe* species.

> *Cap*: 0.3-2.5 cm broad, nearly hemispheric to convex, striated, ocher to dark brown without grey-green stains.
>
> *Stem*: 2-4 cm long, 1-1.4 cm thick, whitish at first, equal to slightly curved at the base, silvery later on, stains bluish-green - particularly at base - in reaction to injuries or with age.
>
> *Spores*: 7-10 x 4-5 µm.
>
> *Basidia*: 4-spored, pleurocystidia absent, cheilocystidia present, 18-25 x 6.5-10 µm.
>
> *Habitat*: On grassy areas or moss, summer through fall.

The *Conocybe* genus is a member of the *Bolbitiaceae* family, which is similar to the *Coprinaceae*, a family of dark-spored mushrooms that includes the *Panaeolus* species.

The *Conocybe* species are very rare in Europe. The mushrooms are hardly ever found among lists of mushroom discoveries from European countries. Aside from Schaffer's discovery, the mushroom was reportedly found or described only twice (!) within the territory of the former East Germany over the last 60 years (both discoveries were made during the 1980s). However, there are only few mycologists who specialize in the study of the *Conocybe* genus, due to its lack of attractiveness.

Even though the mushroom is very rare, I was able to include one picture of *Conocybe cyanopus* in this book (see Figure 36, p. 57). I also had the good fortune to obtain a dried *Conocybe cyanopus* sample for chemical analysis (see Table 9, p. 56).

Psilocybin was discovered for the first time in a sample of fruiting bodies of the species *Conocybe cyanopus* which had been collected on September 4, 1961 in Seattle, WA. No psilocin however mysterious they may remain.

In 1977, Repke and his research team reported the discovery of baeocystin, as well as psilocybin in a *Conocybe* species from the United States and Canada. Once again, no psilocin was found in these samples. Finally in 1982/83, Norwegian researchers confirmed the existence of trace amounts of psilocin, in addition to 0.33-0.55% of psilocybin, an alkaloid that was also reportedly discovered in Finnish samples. Finally, Beug and Bigwood reported 0.93% of psilocybin in samples collected in the Northwestern United States. Interestingly, the second sample ever discovered in Eastern Germany was found on July 2, 1989 near Potsdam, where several fruiting bodies of the *Conocybe cyanopus* species were growing in a grassy area on sand. The original area, however, where Schaffer first discovered the species 60 years ago, lay within the Potsdam city limits and its exact location can no longer be determined.

The sample collected in 1989 consisted of five mushrooms that were found to have concentrations of psilocybin and baeocystin similar to levels found in *Psilocybe semilanceata*:

Table 9
Selected Test Results on the Alkaloid Content of *Conocybe cyanopus*
(% of Dry Weight)

Mushroom	Dry Weight (mg)	Psilocybin	Baeocystin
1	5	0.84	0.15
2	6	0.73	0.12
3	7	1.01	0.20
4	10	0.91	0.16
5	12	0.89	0.14

Concentrations of psilocybin were strikingly similar to those found in samples collected in the Northwestern United States.

After several days, spores from one of the fruiting bodies germinated on malt agar and, compared to other species, proceeded to grow very slowly into their permanent forms or "sclerotia" (see Figure 35, p. 57). The sclerotia showed no blue discolorations, and were found to contain 0.25% psilocybin when dry, while no additional alkaloids were detected.

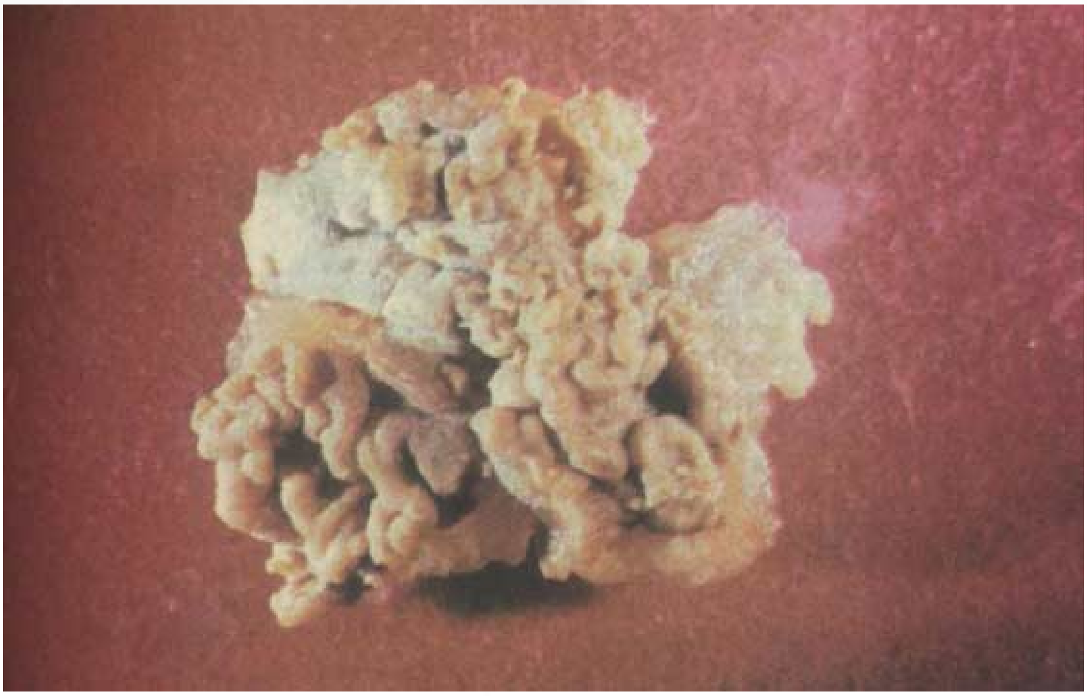

Figure 35 - Sclerotia of ***Conocybe cyanopus*** grown on malt agar.

In summary, it is reasonable to assume that due to its small size and extreme rarity, *Conocybe cyanopus* is a species that is not a significant contributor to intoxications in Europe, nor is it likely to gain such prominence in the future. My own analyses of other, nonbluing *Conocybe* species, such as *Conocybe tenera* (Schaeff.:Fr.) Fayod and *Conocybe lactea* (Lge) Metrod revealed the presence of physiologically inactive ingredients only.

Samples of *Conocybe* species from warm countries have not yet been analyzed and may yet yield remarkable results in terms of chemical composition and alkaloid content.

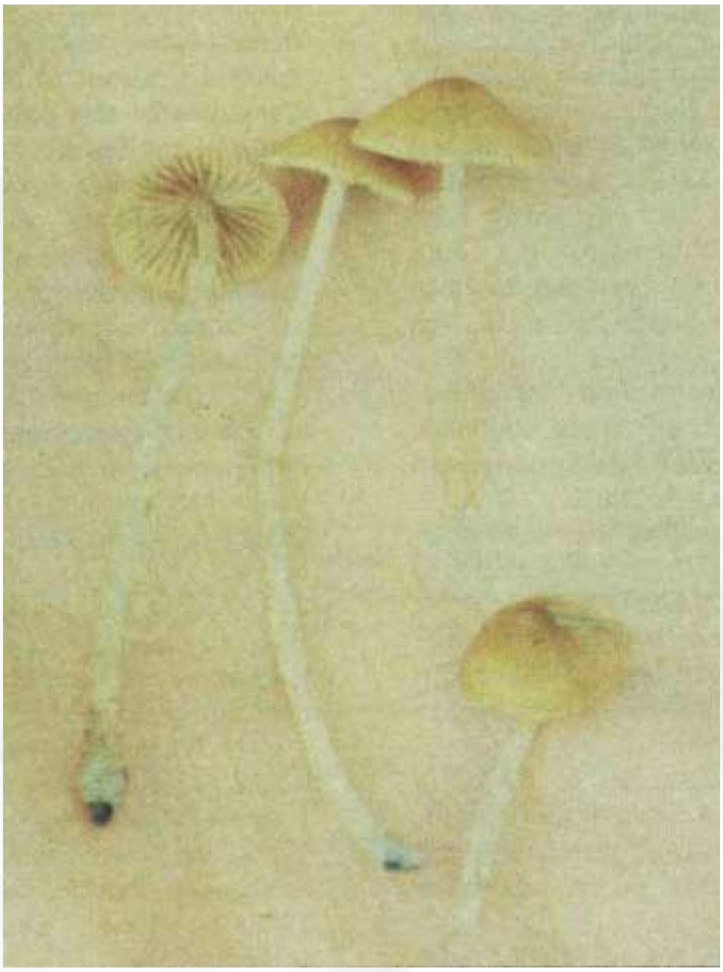

Figure 36 - Fresh ***Conocybe cyanopus*** fruiting bodies from the Pacific Northwest (USA).

3.7 - *Pluteus salicinus*: A Little-known Wood-Inhabiting Species

Within the Pluteaceae family, there are about 45 European species of the genus *Pluteus*, some of whom also produce psilocybin.

Historically, the *Pluteus* species were classified as belonging to the Amanitaceae family, which also include the "death cap" and its relatives, as well as the fly agaric mushroom, both of which belong to the genus *Amanita*. Unlike all the other psychoactive mushrooms mentioned here in this book, the *Pluteus* species are classified as light-spored mushrooms, because of their rose-colored spore dust.

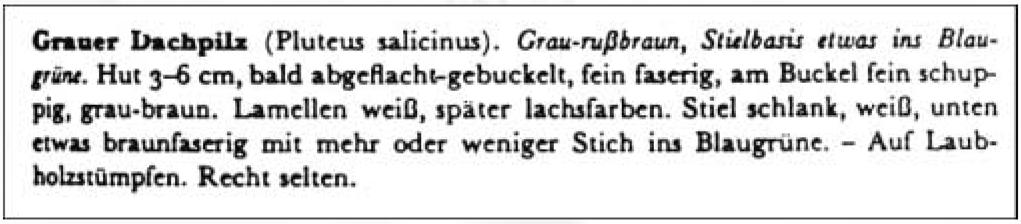
No accidental intoxications involving *Pluteus* species have been documented in the literature.

The first description providing qualitative evidence for the presence of psilocybin and psilocin was provided by Saupe in 1981, who examined extracts of *Pluteus salicinus* (Pers.:Fr.) Kumm. from Illinois. Surprisingly, psilocin turned out to be the alkaloid with the highest levels of concentration in the samples tested. This mushroom species had previously been described in Europe about 200 years ago. Since then, however, it has rarely been mentioned in the literature, and only briefly, if at all (see Figure 37, p. 59).

Some taxonomic methods of classification used earlier can still cause confusion today. For example, Ricken (1915) designated the mushroom as *Pluteus petasatus*.

By way of expanding the description from 1962 (see Figure 37), *Pluteus salicinus* is identified by the following characteristics:

> Medium-sized mushroom with a more or less intensely bluish to bluish-green coloration. Older mushrooms are sometimes colored olive green.
>
> Caps in some cases up to 8 cm in diameter, lighter colored around the margin, silver grey, hairy and felt-like, even hairier and felt-like towards the middle of the cap, often scaly.
>
> Stems up to 10 cm in length, with spontaneous grey-green or grey-blue discolorations at the base, colors intensify in response to pressure.



Grauer Dachpilz (Pluteus salicinus). *Grau-rußbraun, Stielbasis etwas ins Blaugrüne.* Hut 3–6 cm, bald abgeflacht-gebuckelt, fein faserig, am Buckel fein schuppig, grau-braun. Lamellen weiß, später lachsfarben. Stiel schlank, weiß, unten etwas braunfaserig mit mehr oder weniger Stich ins Blaugrüne. – Auf Laubholzstümpfen. Recht selten.

Figure 37 - Description of ***Pluteus salicinus*** from 1962 (Germany). See page 58 for description in English.

There are also mushrooms of this species that are white in color (see Figure 38, p. 60). However, these albino fruiting bodies have stems whose bases show a slight grey-green coloration as well, as do the apex areas of their caps. *Pluteus salicinus* has been described as being anywhere from "very rare" to "not rare" in the wet deciduous forests of Europe. The species of the genus *Pluteus* are final wood-destroyers, that is, they grow saprophytically on wood that appears rotten and discolored, because it has decomposed due to the presence of other mushrooms over the course of many years. *Pluteus salicinus* fruits from May to October on stumps of willows, alder-trees, lime-trees, beech-trees, poplars, maple-trees and possibly on the wooden remnants of other tree species as well. The fact that this mushroom has not been the cause of any intoxications may be explained by its fruiting bodies' occurrence on tree stumps as single mushrooms or in groups of very few mushrooms. Also, compared to other wood-inhabiting mushrooms, *Pluteus salicinus* is not very attractive in appearance. The mushroom's habitus is well illustrated by Figure 39 (p. 60).

For unknown reasons, Kreisel described all *Pluteus* species as "non-poisonous" in his 1987 handbook of mushrooms, despite the fact that psilocybin (0.35% of dried mushrooms) had already been discovered in samples of this species in 1981 (North America) and 1984 (Norway). The alkaloid was also found in mushrooms from Holland, Finland, Sweden and France. The latter tests, however, were limited to very few fruiting bodies in each case.

Whereas Stijve found an average of 0.25% of psilocybin in dried mushrooms from 20 samples collected in Switzerland from 1984 to 1986, my own analyses of non-bluing (!) mushrooms collected in Thuringen, Germany in 1986 yielded much higher alkaloid concentrations:

Table 10
Psilocybin and Urea Content of *Pluteus salicinus*
(% of Dry Weight)

Sample #	**Psilocybin**		**Urea**	
	Cap	Stem	Cap	Stem
1	1.38	0.48	2.50	Traces
2	1.57	0.71	2.60	0.00
3	1.57	0.71	2.60	0.00
4	1.22	1.14	1.40	0.00
5	1.39	0.64	2.40	0.43

Additional analyses of four bluing mushrooms collected in the Dubener marshlands (Eastern Germany) in 1988, confirmed the presence of only about 0.2 - 0.7% psilocybin in those mushrooms. This sample also contained very small amounts of baeocystin.

These results indicate that the variability in alkaloid content in *Pluteus salicinus* has not yet been sufficiently calibrated. Therefore, more analyses are needed. In contrast to the findings based on studies of mushrooms collected in America, it is certain that the European mushrooms produce only traces of psilocin at most.

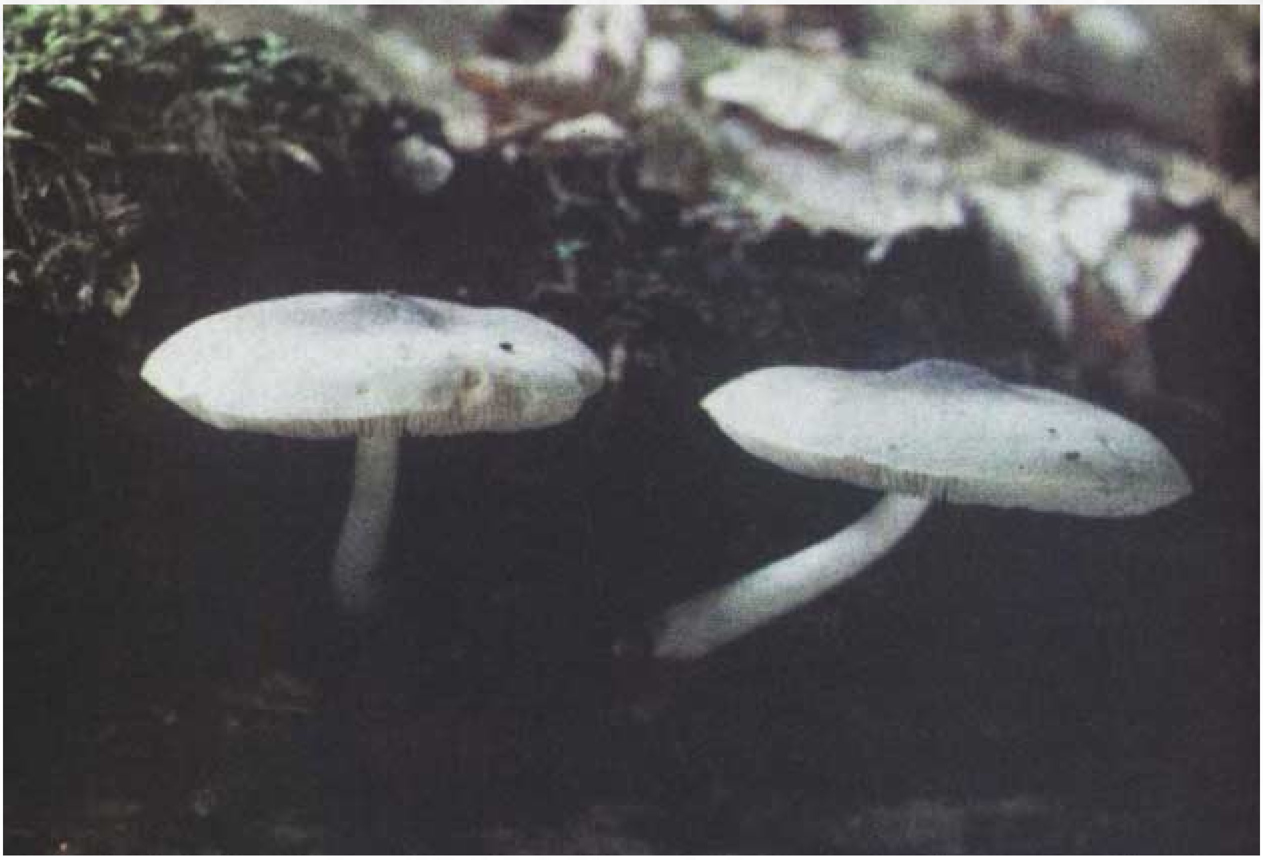


Figure 38 - ***Pluteus salicinus*** at a natural location (Germany).

Stijve and Bonnard were able to examine original material collected by Saupe in the United States. To their surprise, they discovered that the mushrooms were not identical to those found in Europe. They also did no longer contain any alkaloids. These findings show that mushrooms of the same name from different continents are not necessarily identical.

All other *Pluteus* species tested so far contained urea, a substance that can also been found in the *Panaeolus* species. However, the latter also produce compounds like serotonin, which do not occur in the *Pluteus* species. Hence, the different species are once again identifiable by their unique "fingerprints".

Other rare *Pluteus* species with bluish or violet discolorations are mentioned in the literature, such as a *Pluteus cyanopus* from Europe. However, so far, very small amounts of psilocybin (0.035% of dried mushrooms) have been found only in *Pluteus nigroviridis* Babos, an extremely rare species from Hungary.

Therefore, additional analyses of this fairly neglected genus are urgently needed.

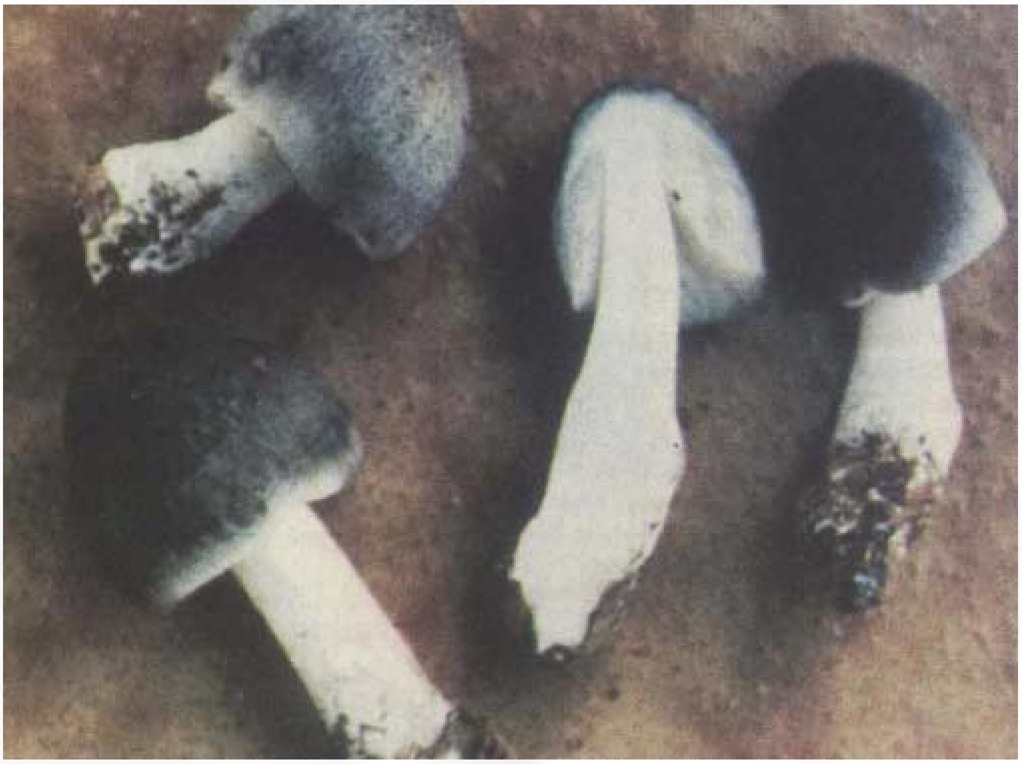

Figure 39 - Fresh ***Pluteus salicinus*** fruiting bodies.

CHAPTER 4

Mushroom Identification: Taxonomic Confusion and the Potential for Deadly Mistakes

> *On December 16, 1981, three teenagers hunting for psychoactive mushrooms on Whidbey Island, WA (USA) collected specimens of a* Galerina *species, in the mistaken belief that the mushrooms belonged to a* Psilocybe *species. All three of them fell ill after eating the mushrooms, but did not report their symptoms or seek medical help for another two days, afraid of being prosecuted for using psilocybin. After medical treatment, two of the teenagers made a full recovery. The third victim, however, a 16 -year-old girl, died on December 24, 1981.*

As presented by Beug and Bigwood, this tragic incident underscores the dangers inherent in careless or erroneous identification of mushroom species, especially when a situation is complicated by overzealous legislative and punitive measures. The psilocybin-producing species as well as culinary mushroom varieties often share some characteristics with many other species. Casual mushroom hunters and lay-persons are especially prone to making identification errors, suffering accidental inoxications as a result. Previous chapters included several case histories of such involuntary intoxications. To be sure, modern mycological keys are valuable tools when it comes to accuracy in deciding the family and genus of an unknown mushroom sample. It can be extremely difficult, however, to identify the specific species of questionable specimens, especially if the sample belongs to the vast category of "LBM"s, or "little brown mushrooms". We currently know very little about the "LBM" species, since their habitats and variations in habitus have not been studied in systematic detail. Not surprisingly, reference books are often limited by incomplete descriptions that lack the essential criteria for differentiating one species from others that are similar or related. I vividly recall my own first attempts to identify unknown samples by relying on what appeared to be precise definitions in standard mycological reference works. I found many of the listed traits to be descriptive of a wide range of sometimes very different species. As I compared my samples with the text, I noticed a tendency to disregard some of the finer details in the literature, so that "my mushrooms" would better match the descriptions. Naturally, this approach resulted in errors. Luckily, I would quickly discover and correct my mistakes upon consultation with my mycologist friends. In my experience, competence and expertise in the area of mushroom identification are skills honed over time through extensive fieldwork, consultations with established mycological experts, and careful analyses of samples based on information found in appropriate reference books.

The literature clearly indicates that *Psilocybe semilanceata* is one species that, at prime locations, can be easily identified without consulting a diagnostic key. *Psilocybe semilanceata* is known for its uniquely distinctive appearance, so that microscopic tests are not needed to distinguish this species from other pasture-dwelling mushrooms. The situation is different, however, for *Psilocybe* species that thrive on wood debris, as illustrated by the tragic story at the beginning of this chapter. Besides, compared to Europe, the North American mycoflora includes a much broader and varied spectrum of mushroom species to begin with.

Warning: Amatoxins are Lethal!

The *Galerina* genus includes a number of poisonous mushrooms. These species are dangerous, because they contain the same deadly amatoxins as the "death cap" (*Amanita phalloides*) and its relatives, "death angel" and "destroying angel". Their toxins are insidious, with no symptoms evident for about 12 hours. During this latency period, the toxins can cause major irreversible internal damage, which is why many cases are fatal in spite of treatment. A common North American species is *Galerina autumnalis* (Peck) Singer & Smith, which grows on wood debris in parks and forests, just like several of the *Psilocybe* species. At first glance, *Galerina autumnalis* resembles *Psilocybe stuntzii* Guzman & Ott, and the two species may grow side by side at the same location. The *Galerina* species, however, does not turn blue. I once discovered a grassy area that was home to a cluster of *Psilocybe stuntzii* specimens entangled with a *Galerina* species. The mushrooms had grown so entwined that individual fruiting bodies could be identified only by spore analyses.

Pholiotina filaris (Fr.) Sing. (also known as *Conocybe*) is another North American species known to contain amatoxins. At the same time, these toxins have not been found in European samples of this species. Thus, *Pholiotina filaris* (Fr.) Sing. most likely does not refer to the same species on both continents. Still, at least one European *Galerina* species (*Galerina marginata* (Fr.) Kuhn.) contains the same toxins found in the "death cap" mushroom. This species also grows on decaying wood substrate and its fruiting bodies contain about one-third of the amount of amanitines found in *Amanita phalloides*. Incredibly, older mushroom books list *Galerina marginata* as an edible species.

In a previous chapter on the *Panaeolus* species I illustrated the potential for identification errors associated with commercial cultivation areas that are "invaded" by outside species. Due to their rapid growth, the *Panaeolus* species in particular will often fruit in artificial growing areas long before the cultivated species that is grown there. Chapter 3.3 details the 1970 poisoning incident involving *Panaeolus subbalteatus* from a cultivation area in Leipzig. In that case, the intruding species was mistaken for *Stropharia rugoso-annulata* Farlow (the Giant *Stropharia*), based on information from a mushroom book. Apparently nobody realized the glaring differences between the book's description and the actual characteristics, except for the assumption that the sample's small size meant the mushrooms simply had not grown as tall as portrayed in the book. This flawed conclusion illustrates a type of judgment error common among amateur mushroom hunters who falsely believe that they are experts. Having been shown a single sample of wild mushrooms, for example, some mycophiles become convinced they will always be able to recognize the species in the future. That is how one such mushroom hunter accidentally ingested *Inocybe aeruginascens* specimens that he believed to be common fairy ring mushrooms. In a similar case of *Inocybe aeruginascens* intoxication, the mushrooms had been picked as white champignons, even though this common culinary mushroom bears no resemblance, either in size or form, to *Inocybe aeruginascens*. Overall, however, these unfortunate cases have also contributed to our understanding of mushroom biochemistry.

In this context, I want to emphasize once more that the hallucinogenic varieties among the *Inocybe*s can easily be mistaken for those muscarine-producing *Inocybe* species that are extremely poisonous.

As part of his investigation of the *Psilocybe* genus, Guzman noted a common trait among the hallucinogenic species, in addition to the bluing reaction: a flour-like smell or taste. Apart from the inherent subjective nature of our sense of smell and taste, a common odor is a trait that definitely does not apply to the European species (also see Chapter 3.2).

Mycophile or Mycophobe?

There are reports from the Western United States about people with expert knowledge of *Psilocybe semilanceata* - devoted mushroom hunters who can identify the species with drill and accuracy. At the same time, however, these experts cannot identify easily spotted common table mushrooms, nor are they able to differentiate the *Agaricus* species (champignons) from other mushrooms, even when these species grow on the same pasture. Such individuals, then, are not interested in species other than *Psilocybe semilanceata*. In my opinion, this attitude reflects a rare combination of mycophilia and mycophobia.

A mushroom's spore dust provides important information needed to determine identity. A spore print is left by the gills when the cap is placed on black or white paper (depending on spore color). As the process takes several hours, a glass vessel must be placed over the cap to prevent drying. While useful, information obtained from spore analyses has its limitations. For instance, spores derived from mushrooms belonging to different genera may have the same color, but reveal basic differences under the microscope. There is also a high degree of similarity among spores from different *Psilocybe* species. Thus, the only way to prevent grave errors and potentially deadly intoxications is to rely on experienced experts for mushroom identification, a process that must include analysis of available ecological data.

CHAPTER 5

The Bluing Phenomenon and Metol Testing: Reality vs. Wishful Thinking

As previously discussed in Chapters 3.1 and 3.7, the bluing reaction is characteristic of species that produce psilocybin. Still, for unknown reasons, some species or samples belonging to a genus that usually turns blue may not always change color, regardless of psilocybin content. Among the species that I have examined, *Psilocybe bohemica* displayed the most impressive bluing reaction. The caps of this species stain very quickly in reaction to pressure. Other species, such as *Psilocybe cubensis* (Earle) Sing. have stems that develop very intensely blue stains, while their caps do not exhibit the bluing reaction. By contrast, *Psilocybe semilanceata*, *Conocybe cyanopus* and *Inocybe aeruginascens* are species whose stems develop only slight stains in reaction to pressure and only after a relatively long time period has elapsed. With respect to time delay and intensity of the bluing reaction, *Gymnopilus purpuratus* is a species that falls in between these two extremes.

A Rich Color Spectrum

The colors range from green to a deep blue. *Psilocybe cubensis* is a species in which the latter color may also take on a blackish-blue hue. The mechanisms underlying the color reactions in these mushrooms has not yet been studied. I have already mentioned Cooke's speculation from the early years of the 20th century about the significance of the bluing reaction in *Psilocybe semilanceata* (see p. 16). In the 1950s, it was Singer and Smith who emphasized that discolorations observed in the psychotropic *Psilocybe* and *Panaeolus* species must somehow be linked directly or indirectly to the mushrooms' active ingredients. Eventually, in 1958, A. Hofmann and his collaborators reported the successful isolation of these ingredients. They were the first to observe that pure psilocin grows unstable when exposed to oxidizing agents such as air and that solutions of psilocin turn bluish-green in an alkaline range.

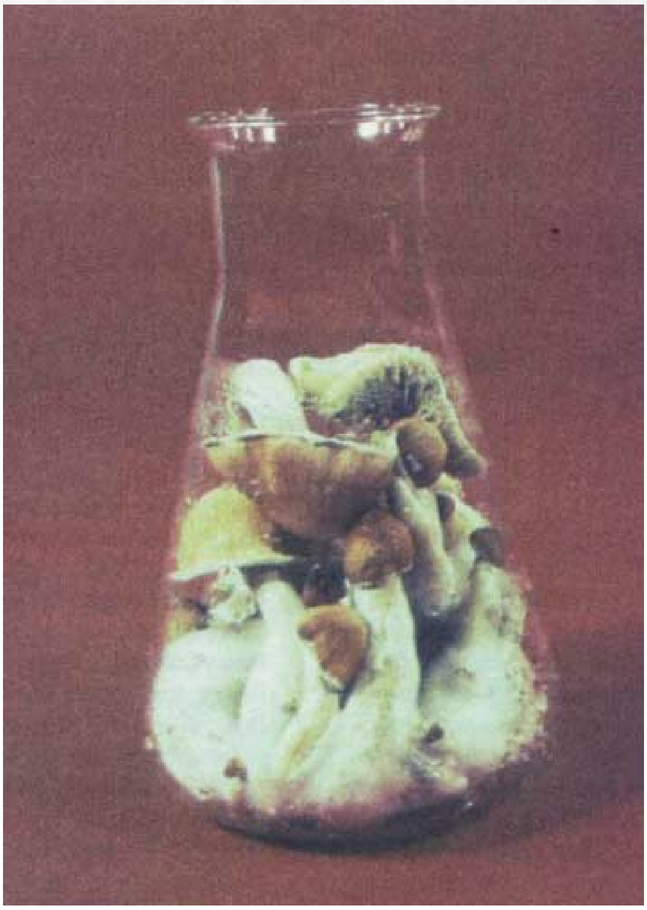

Figure 40 - ***Psilocybe cubensis*** fruiting bodies whose growth was accelerated with plant hormones.

These results provided proof that the bluing reaction resulted from a mushroom ingredient's breakdown by oxidation. From 1960 on, Blaschko, Levine and Bocks, as well as Horita and Weber performed in-vitro studies of the biochemical reactions of psilocybin and psilocin. They concurred that only psilocin can be oxidized into a product of bluish-green color. The phosphate group prevents direct oxidation of this alkaloid (see Figure 19, p. 27). However, the typical bluing phenomenon does occur when this protective group is removed by enzymes, such as various phosphatases, which are very common in human as well as in mushroom tissue. I also observed the bluing reaction following removal of the phosphate group from baeocystin. Observations from in-vitro experiments explain why *Psilocybe bohemica* displays a strong bluing reaction, despite the fact that levels of psilocin in this mushroom are low or nonexistent: Apparently, the enzymatic removal of the phosphate group from the psilocybin molecule occurs quite quickly. This is how psilocin is formed in reaction to injuries to the fruiting bodies. Immediately afterwards, psilocin continues to break down and disappears completely, while a number of blue-colored substances are created. In addition, some enzymes were discovered which accelerate the breakdown of psilocin. Cytochrome oxidases and laccases are examples of such enzymes. The latter has also been found in the mycelia of *Psilocybe cubensis*. Most likely, the enzymes are also formed in those mushrooms that display bluish discolorations in reaction to metol testing. Trace amounts of Iron ions accelerate the bluing reaction as well. The structure of the blue-colored compounds has not yet been investigated. Apparently, they are quite unstable and involve a type of chemical bond known as chinones. Many pigments are known to have this basic structure.

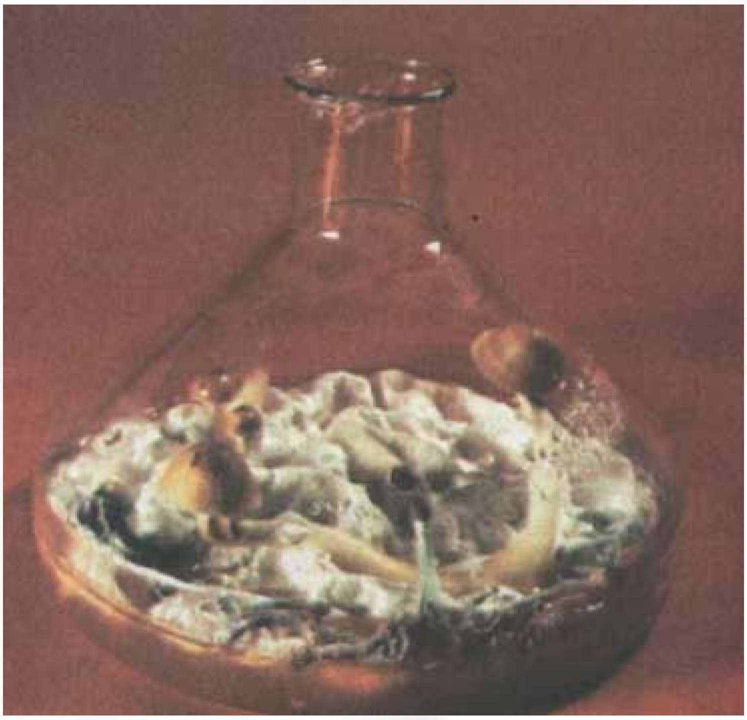

Figure 41 - Mycelial culture of ***Psilocybe cubensis*** on malt extract (3% solution).

The *Agaricales* as Alkaloid Producers

Even though the blue discoloration does not occur in all mushroom species that produce psilocybin and psilocin, we can say that, conversely, all species of the order *Agaricales* (gilled mushrooms) displaying this reaction are capable of producing alkaloids. Historically, this problem associated with the bluing reaction did not particularly impress early mycologists, because there were a number of boletes which turned blue in reaction to pressure and were thought to be among the most valued culinary mushrooms. Indeed, the mushrooms' color reaction is based on ingredients that are physiologically inactive. The boletes also do not display the kinds of spontaneous discolorations with age that are frequently noted in the psychotropic species.

As results of my own analyses have shown, the alkaloid concentrations in *Psilocybe semilanceata* and *Panaeolus subbalteatus* - whose fruiting bodies showed a slight degree of discoloration at most - are within the same orders of magnitude as those found in mushrooms that do not turn blue. Evidently, the pigments involved have a high degree of intensity; the tiny amounts that were produced did not measurably contribute to the destruction of the active ingredients. On the other hand, my own experiments revealed that levels of psilocin and psilocybin in very old and strongly discolored fruiting bodies and mycelia of *Psilocybe cubensis* were considerably lower in comparison to younger specimens. In 1948, Singer was the first to describe the intensification of the bluing reaction, including a change in color towards violet, in samples of *Psilocybe cubensis* which had been moistened with an aqueous solution of the photographic reagent metol (p-methylaminophenol). Ten years later he reported further examinations of some psychotropic *Psilocybe* species whose stems usually turned purple through contact with this reagent. Since 1970, various "field guides" intended to aid in the identification of North American *Psilocybes* have also described this reaction as specific to the *Psilocybe* species. For practical purposes, however, this guideline is all but useless. The metol merely reacts with the laccase enzyme (several structural types) contained in the mushrooms and it is not a reagent able to confirm the presence of psilocybin and its derivatives. Even the brown and white varieties of the commercial champignon mushroom change colors when exposed to a metol solution, just like many other mushrooms do as well.

The Limitations of Reagents

The discovery and usage of different color reagents as a means to differentiate certain species or even genera has been attempted for quite some time, with only moderate success, for the most part. Melzer's Reagent is a well-known mixture whose usage was propagated as a method for identifying the *Psilocybe* species. For this purpose, however, it turned out to be just as nonspecific and worthless as metol.

G. Drewitz discovered that the application of iron chloride to fruiting bodies of *Inocybe aeruginascens* caused a deep blue discoloration, while the muscarine-producing species of the same genus did not change color. Iron chloride is a salt that reacts with different phenoles to form intensely blue molecules. The underlying mechanism of this reaction is more realistic than the others, because psilocin will also react as a phenole. Independent of this color formation, mere trace amounts of iron ions will suffice to accelerate the oxidation of psilocin by air.

However, *Inocybe aeruginascens* is a species that produces only trace amounts of psilocin; therefore, it is very likely that the iron salt reacts with other phenoles in this mushroom species.

In summary, only those bluing reactions that are spontaneous or caused by injuries provide reliable clues as to the presence of psilocybin and its derivatives in *Agaricales*. The presence of the bluing phenomenon itself, however, reveals nothing about the type and quantity of any specific indole compound that may be present in gilled mushrooms.

CHAPTER 6

Mushroom Cultivation: Classic Findings and New Techniques

While conducting research on the Mexican mushroom species during the 1950s, R. Heim and R. Cailleux determined the basic conditions essential to the cultivation of various mushrooms. Before providing additional details, I would like to briefly summarize the nutritional requirements and characteristics of fungal growth, to the extent that these issues are of interest here.

Extraterrestrial or Earthly Organisms?

In terms of cultivation parameters and nutrients, the psychotropic species are no different from table mushrooms and other common gilled mushrooms. For that reason, Oss and Oeric's speculations about extra-terrestrial origins of these species clearly belong into the realm of fables. In addition, psilocybin and psilocin are substances that can be derived from tryptophan by means of discernable reactions; indeed, the amino acid tryptophan in its free form has been found in a large number of mushroom species.

The natural propagation of higher mushrooms is linked to their basidiospores, which are produced on the gills of developing fruiting bodies and which are eventually cast off. Once the spores have been dispersed - by the wind, for example - they will germinate when conditions are favorable (nutrients, temperature, moisture, lack of competing organisms) and finally, they gradually colonize available substrates. Initially, a monokaryotic mycelial thread (i.e. a mycelium with only one nucleus per cell) grows out of the spore and superficially penetrates the nutrient substrate. When two of these hyphae meet, they form a mycelium with two nuclei, or a dikaryotic mycelium ("mycelial network"). Later on, these mycelial strands go on to differentiate into spore-producing fruiting bodies ("fruiting"). Eventually, their spores disperse and germinate once again.

During most parts of the year, the dikaryotic mycelium grows unnoticed in its natural substrate and remains purely vegetative, that is, it continues to spread and to utilize new nutritional resources without producing mushrooms, provided there is sufficient moisture and temperatures do not drop below freezing. ln its dormant state, the mycelium can weather droughts and the cold temperatures of winter, only to begin to grow anew. Some species have mycelia with thick strands that are visible within the substrate (e.g. the rhizomorphs of *Psilocybe cyanescens*), while other species, such as *Psilocybe semilanceata*, develop comparatively thin strands that are hardly visible at all.

The Secret of "Overnight" Growth

Every mushroom collector knows that there are years of maximum mushroom yields. Other years, mushrooms are scarce and dry periods may pass with no apparent crops of gilled mushrooms or boletes. For the majority of mushroom species, the specific conditions required to reach the fruiting phase have not yet been determined.

The saprophytic species (including the hallucinogenic ones except the *Inocybe* species: mycorrhiza with trees) generally fruit after optimal mycelial growth has been induced by appropriate nutrient substrates, as long as the following environmental conditions are maintained:

1. Decrease of the temperature until time of optimal fruiting.
2. Increase of the humidity to 95-100%.
3. Decrease of carbon dioxide concentration through increased air circulation.
4. Exposure to light may be necessary for fruiting.

The last two items already touch upon the essential requirements for mushroom cultivation, since these conditions are always present in Nature, but often need to be specially created for mushroom cultivation inside glass containers or enclosed rooms.

It is no coincidence that the saprophytic species almost always fruit during the fall. Plant substrates such as twigs and leaves fall to the ground during this time and they are immediately colonized by available mycelia from mushroom spores as part of the natural cycle. The concurrent drop in temperature and increase in humidity are preconditions for fruiting. The proverbial rapid growth of mushrooms "overnight" is a function of mycelia that have previously massed together into knots, followed by a differentiation process into primordia, with progressive divisions into caps and stems. The whole mushroom is then ready to develop very rapidly, given sufficient moisture and ideal temperatures. Figure 42 illustrates a comparable in-vitro fruiting process that took about a week, with mycelia from *Psilocybe cubensis* (Earle) on an agar substrate.

Cultivating High Yield Strains

Artificial cultivation is an attempt to imitate and optimize the natural conditions essential for mushroom growth, and may even result in the discovery of additional nutrient substrates on which these species cannot grow in Nature. From the outset, this method of cultivation requires a sterile environment, in order to eliminate often fast-growing organisms such as bacteria and molds. For this purpose, laminar flow hoods are used in mycological laboratories. A small sterile space is created inside these containers by installing a filtration system that removes germs from a stream of air. The sterile space is used for the performance of tasks such as isolation of strains, and the production of sterile cultures and spawn for fruiting experiments. Antibiotics such as gentamycin (0.01%) are often added to the nutrient media, especially in the early stages of this process.

Two methods are used to produce sterile cultures of fungal mycelia.

The first method mimicks the mushrooms' natural reproductive process. Spores that fell off or were removed from the gills are suspended in sterile water. With microscopic control procedures in place, the spore solution is germinated on nutrients of various compositions that have been thickened with agar. One commonly used nutrient medium contains 3-6 malt extract along with 1.5% agar. It induces spores from many different species to germinate in a matter of several days. Prior to germination, all substrates are placed in autoclaves and sterilized with steam. The simultaneous germination of a large number of spores will result in the growth of monokaryotic mycelia which spontaneously combine and go on to form dikaryotic mycelia. Alternatively, one can attempt to systematically fuse selected monokaryotic strands in order to develop vigorous strains for cultivation (criteria: rapid growth, high yield). This is a standard technique that is widely used in the cultivation of champignons (*Agaricus bisporus*).

At the same time, such cross-breeding experiments enable the grower to determine whether mushrooms from different locations belong to the same species. Using this method, I was able to establish that mycelia obtained from *Psilocybe bohemica* and from *Psilocybe cyanescens* (collected in the U.S.) can never be fused together, which means that these two mushrooms are not of the same species.

The second method of cultivation requires cutting a piece of tissue from the inside of young, unopened fruiting bodies, using a disinfected knife in a sterile environment. The piece of tissue is then placed onto nutrient agar medium. In most cases, visible mycelial growth will occur within a few days. This method has the advantage of all mycelia being genetically identical to the mushroom from which they originated, unlike mycelia grown from spore samples. Therefore, this method makes it easy for the grower to reproduce high yield strains of saprophytic species. Some wild strains obtained from various species do not fruit at all when cultivated, or else, they do so very late, with a yield of fruiting bodies that is sparse at best.

Such differences in response to attempted cultivation were also observed by R. Heim with various strains of *Psilocybe mexicana* Heim. As early as 1956, he took spore sprints from a number of fruiting bodies in Mexico. Later on, in Paris, he was able to germinate the spores and isolate mycelial cultures of five different species. In collaboration with R. Cailleux, Heim succeeded at growing fruiting bodies of the species *Psilocybe mexicana*, using compost substrate as a medium. This type of substrate is the most widely used nutrient soil for commercial mushroom cultivation (champignons). The fruiting bodies grown by Heim and Cailleux provided the dried material that A. Hofmann and his collaborators used to isolate psilocybin and psilocin for the first time. In Basel, it was also possible to cultivate mycelia from different species on liquid solutions of malt extract. The mycelial tissue was found to produce psilocybin without having to go through the fruiting process.

This important discovery became the basis for harvesting large amounts of alkaloids. Unlike the fruiting process, which yielded five harvests over the course of several months, a species' mycelial cultures produced much larger amounts of mushroom tissue in only four weeks (see Figure 41). The cultures were grown on stationary malt extract (4-6%) with 0.2% agar added for increased viscosity.

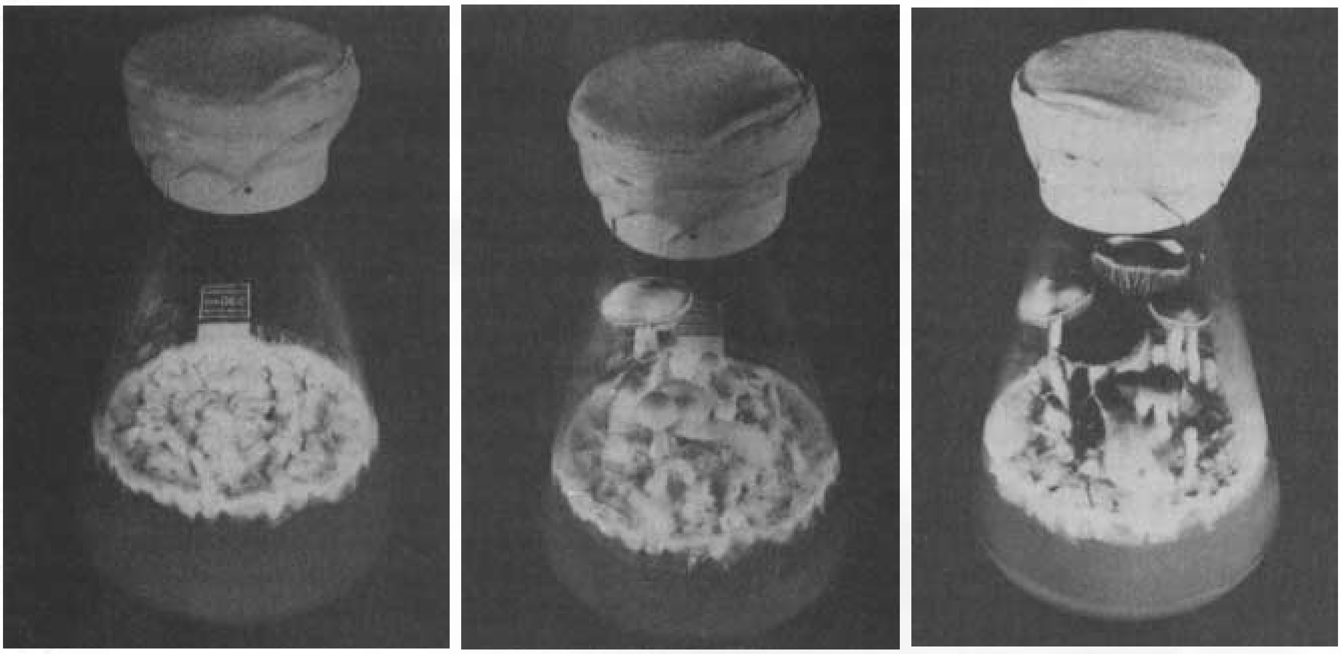

Figure 42 - One-week growth progression of ***Psilocybe cubensis*** cultivated on a malt agar (2%) substrate.

This kind of saprophytic surface cultivation can be easily adapted for growing species which are difficult to fruit under in-vitro conditions, such as *Psilocybe zapotecorum* Heim, permitting cultivation of these species for alkaloid production. Even though the mycelial tissue grown from the Mexican species contained only half as much psilocybin (0.1-0.2% of dry weight) as the mushrooms did, high yields (approximately 20g/l) along with easy and rapid cultivation of mycelial tissue more than compensated for the lower psilocybin content. It is interesting to note that mycelia from the North American species of *Psilocybe cyanescens* will turn blue and accumulate psilocybin when grown on a medium of solid malt agar, while both of these traits disappear completely when the same strain is cultivated on the type of liquid medium described above, even if levels of nutrients are identical. The reasons for this inconsistency remain a mystery.

When mycelial cultures are kept in the dark, the mycelial forms may become partially permanent (sclerotia). Sclerotia may be hardened, are largely dark to black in color and they contain psilocybin as well. The formation of sclerotia was initially observed as part of the first-ever attempt to cultivate psychotropic mushrooms on an agar medium. In 1935, H.J. Brodie reported permanent formations of bluish-green tissue while cultivating *Panaeolus subbalteatus* on malt agar.

Initially, he believed that his nutrient substrates had been contaminated by molds, because *Panaeolus subbalteatus* is a species that almost never spontaneously turns bluish-green. Figure 47 shows a distinct sclerotia formation of the species *Psilocybe semilanceata*. The formation of these permanent structures with *Conocybe cyanopus* has been described in a previous chapter (see Figure 35, p. 57).

Heim and Cailleux primarily described the fruiting of *Psilocybe mexicana* and *Psilocybe cubensis* on agar (0.05-2% malt extract) and on compost. During their experiments, *Psilocybe mexicana* produced the highest yields, while *Psilocybe cubensis* fruited quite vigorously as well. At about the same time, R. Singer had also started mycelial cultures derived from six mushroom species. Singer and his co-workers soon concentrated on *Psilocybe cubensis* in their efforts to induce fruiting. Soon after, in the early 1960s, R. L. Kneebone reported that this robust mushroom species, which thrives across subtropical climate zones, can also be induced to fruit on a rye-grain medium.

Counter-Cultural Expertise Gains Mainstream Acceptance

In the mid-1960s, *Psilocybe cubensis* became the species of choice for experiments that made use of submersed fermentation to investigate the biosynthesis of psilocybin from tryptophan and other precursors. We should note in this context that around the same time, this technique was also used to obtain mycelial pellets of the species *Psilocybe baeocystis* Singer & Smith, providing the material for the first-ever isolation of baeocystin from mushroom tissue.

From the 1970s on, a growing number of books were published in the United States that distributed information acquired by members of the counter-culture on the cultivation of psychotropic mushrooms. The scope of these books soon narrowed, with a primary emphasis on *Psilocybe cubensis*, which may be explained by the fact that, initially, only R. Heim's research results were published, thus making them available to a larger audience.

In 1971, new results were published about the champignon's ability to fruit on a rye grain medium, provided a cover layer was added on top. It wasn't long before these findings were applied to the cultivation of Psilocybe species.

By 1932, J. Sinden had already published a patent for a cultivation process that involved the inoculation of mushroom mycelia derived from champignons into horse dung compost (a medium widely used for cultivation purposes) but only after the mycelia had already grown to permeate a medium of sterilized grains. Since that time, this process has mainly been used in the production of table mushrooms, specifically, for manufacturing the spawn to be placed onto the compost without inducing fruiting on grain. *Psilocybe cubensis* fruits after about three to eight weeks on this substrate.

If a moist cover layer is added (e.g. a peat moss/lime mixture, 2:1), the yields may double. However, this process is risky, because over-saturation can render the containers non-sterile and invite contamination from bacteria and molds. Most authors prefer a mixture of rye and water that has been inoculated with mycelia from an agar culture. Still, rice, barley, wheat and other grains have also been used with varying degrees of success. Figure 52 shows that, after about five weeks, small mushrooms even grew on wet pages of a newspaper that used to be the official print medium controlled by the former East Germany's SED Party ("Sozialistische Einheitspartei Deutschlands" or "Unified Socialist Party of Germany").

Some Recent Findings

Today, *Psilocybe cubensis* is clearly one of the most easily cultivated mushroom species around and it can thrive on a large variety of substrates. Naturally occurring specimens are most often found growing on cow dung. Generally, the species tends to grow on dung and straw as a primary decomposer, but the mushrooms can also utilize nutrients previously converted by other organisms, such as various types of compost, among others (see Figure 53, p. 77).

Within the scope of this book, it is impossible to discuss all details pertaining to the fruiting process of psychotropic mushroom species. P. Stamets and J.S. Chilton are the authors of two outstanding books that deal with all the technical and practical aspects of mushroom cultivation. The psychotropic species are included along with information about many kinds of culinary mushrooms. Still, I would like to make special note of the fact that *Psilocybe cubensis* cultures benefit when horse or cow dung is added to the original nutrient mixtures, as evidenced by the mushrooms' relatively faster growth rate and the development of comparatively more robust specimens (see Figure 45, p. 71 and Figure 49, p. 74). Before adding the dung to the nutrient mixture, however, it must first be suspended in water and autoclaved, which considerably reduces the risk of contamination. Only then should the suspension be added to the rye grain substrate and sterilized once more.

In spite of numerous claims in the popular literature, most attempts by laypersons to cultivate fruiting bodies of *Psilocybe cubensis* on rye grain substrate are thwarted by the presence of contaminating agents such as bacteria and molds. Even though mushrooms are organisms that do not perform photosynthesis and thus are no longer thought of as plants, some mushroom species, including *Psilocybe cubensis*, are heliotropes, meaning they will grow toward stationary sources of light. All *Psilocybe* species examined to date require light to promote the biochemical process in the mycelia that will induce fruiting. Additional exposure to light is needed, if the fruiting bodies are to develop into normal shapes and produce spores.

Apart from a series of interesting physiological experiments performed by E.R. Badham during the 1980s, there are a few other noteworthy substrates for cultivation of *Psilocybe cubensis* fruiting bodies. For instance, we were the first to discover that a new type of plant hormone (brassinosteroids) will accelerate fruiting of the mycelia (Figure 40, p. 64). During these experiments, we were also able to completely suppress the formation of psilocybin and psilocin through high concentrations of phosphate. It is now possible to design future physiological experiments to study different hallucinogenic mushroom species under these conditions.

In recent years I have also succeeded at cultivating the European hallucinogenic mushroom species.

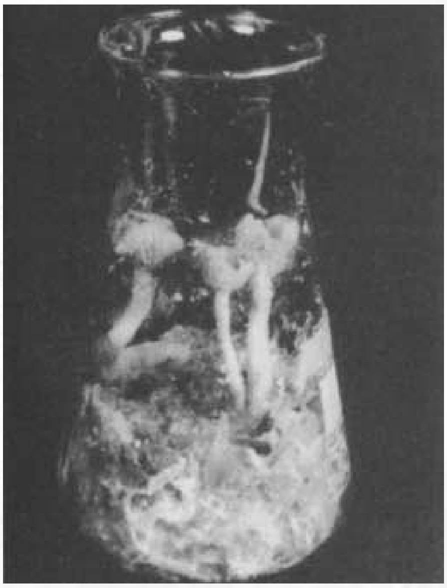

Figure 43 - ***Gymnopilus purpuratus*** fruiting on wet rice and saw dust.

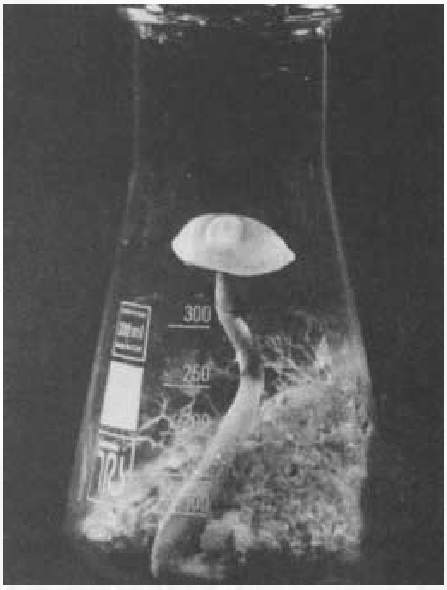

Figure 44 - ***Psilocybe bohemica*** on a rice substrate.

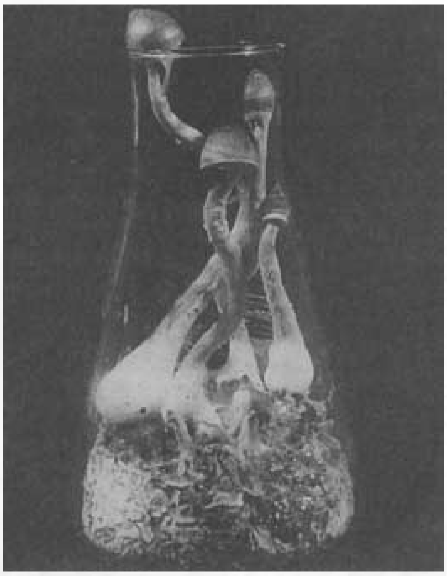

Figure 45 - ***Psilocybe cubensis*** fruiting bodies grown an a mixture of cow manure and rice.

Psilocybe semilanceata is a mushroom species whose mycelia grow at a significantly slower rate than the mycelia of *Psilocybe cubensis*, *Gymnopilus purpuratus*, *Panaeolus subbalteatus* and *Psilocybe bohemica*. Despite the fact that only a few strains of *Psilocybe semilanceata* actually fruited, cultivation of this species succeeded with different substrates. After a mycelial growth period of three to four months, the mushrooms emerged on compost (see Figure 46) as well as on a mixture consisting of grass seeds, dung, and rice (see Figure 66, p. 116). Four flushes of fruiting bodies were observed.

Panaeolus subbalteatus also fruited after 92 days on a mixture of cow dung and damp rice. The physical appearance of these fruiting bodies differed considerably from specimens of the same species that had grown on naturally occurring substrates (Figure 3, p. 6 and Figure 51, p. 76).

According to Stamets and Chilton, *Panaeolus cyanescens* is a species that does not fruit without a cover layer. However, this statement does not seem very plausible, considering the species can be found, much like *Psilocybe cubensis*, growing on top of dung under natural conditions.

Psilocybe bohemica was another species that fruited on damp rice after two or three months. These in-vitro specimens also appeared to be much hardier in comparison to fruiting bodies collected at a natural location near Sazava, Bohemia (Czech Republic). The cultivated specimens even developed two (!) rings, yet these robust mushrooms did not fruit until after an exposure to the shock of cold temperatures (see Figure 44, p. 71).

At about the same time, *Gymnopilus purpuratus* fruited on a moist mixture of rice and saw dust after six to eight weeks (see Figure 43, p. 71). In this case, however, the cultivated mushrooms turned out to be smaller than fruiting bodies that developed from fruiting mycelia on wood shavings at a location outside the laboratory

(Figure 30, p. 40).

During the 1980s, there were also reports about success in cultivating psilocybin-containing sclerotia of *Psilocybe mexicana* and its close relative *Psilocybe tampanensis* Guzman & Pollock. In both cases, the sclerotia form after three to twelve weeks, preferably in the dark on a substrate of lolium (rye grass) seeds. All strains of *Psilocybe tampanensis* originate from a single fruiting body that was found near Tampa, Florida in 1977. Sclerotia from this species have also been cultivated on a straw substrate. Compared to lolium seeds, soft rice has the advantage of not drying out as fast, so that the sclerotia will form more evenly than they would on rye grass seeds. A photograph of *Psilocybe tampanensis* sclerotia is shown on page 117 (Figure 69).

Psilocybe natalensis, which we first discovered in South Africa in January 1994 (see Chapter 7.6), is another species that easily fruits, within four to eight weeks, on compost or on straw with potting soil for a casing.

In closing, I would like to comment on the mycorrhiza problem. Due to the close interrelationship between mushroom mycelia and their symbiotic partner trees, there exists a unique exchange of growth hormones and other products - substances whose study has only just begun. For this reason, all attempts to fruit these species in-vitro have remained unsuccessful. Nonetheless, we were able to start mycelial cultures from some of these species, but in most cases, growth rates remained very slow. As a result of my own investigations, I was able to isolate sterile cultures from *Inocybe aeruginascens* (see Figure 50, p. 75), which grew and developed greenish sclerotia at the same time. The dried mycelial mass contained about 0.1% psilocybin, Figure 48 (p. 74) shows three *Inocybe aeruginascens* fruiting bodies whose mycelia grew naturally. These mycelia were found to contain no baeocystin and less psilocybin (0.05%) than the fruiting bodies shown in Figure 48.

Several months after these mycelia had been isolated from spores and fruiting body tissue samples, they began to degenerate and lost their ability to sustain growth, most likely because information available about conditions and requirements for optimal growth was insufficient.

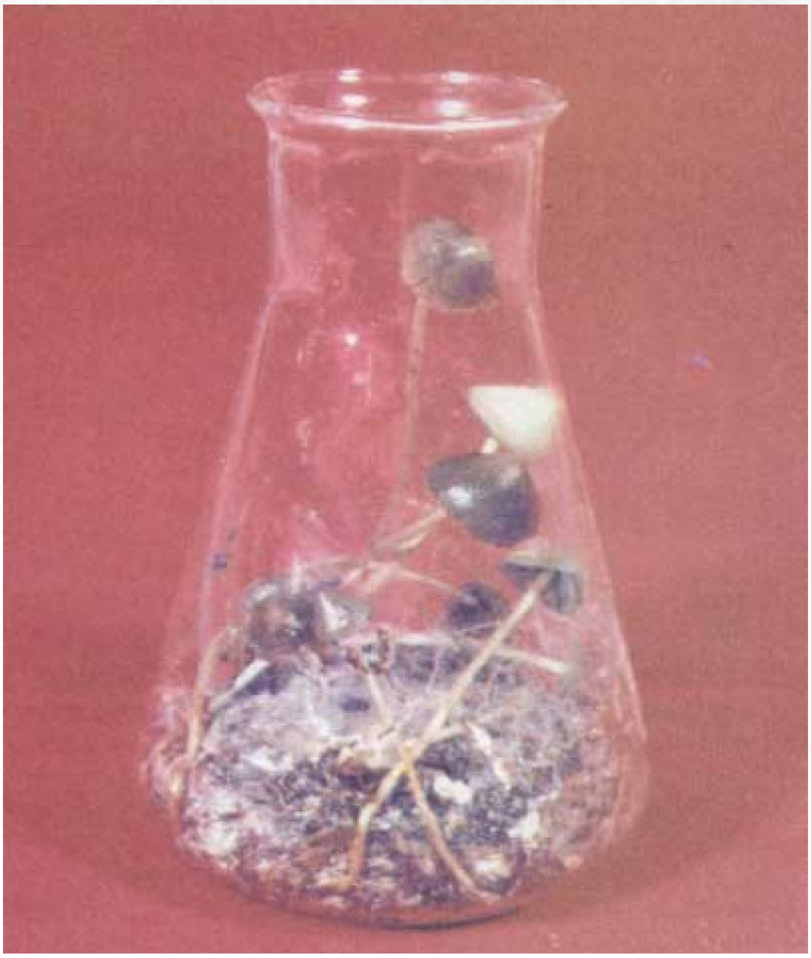

Figure 46 - ***Psilocybe semilanceata*** on compost.

Incidents of mycelial degeneration in saprophytic species have rarely been described in the literature. However, this condition can be easily prevented through usage of more than just one type of nutrient media; thus, the specific composition of a medium should be changed from time to time. In addition, only fast-growing mycelial threads (rhizomorphs) should be selected for propagation. By contrast, prolonged degeneration of strains can be caused by new inoculations of material taken from agar-based portions of mycelia whose texture is somewhat like wool. The kind of viruses known to appear in champignon cultures - where they have already caused a lot of damage - have so far not been found in cultures of the *Psilocybe* and *Panaeolus* species.

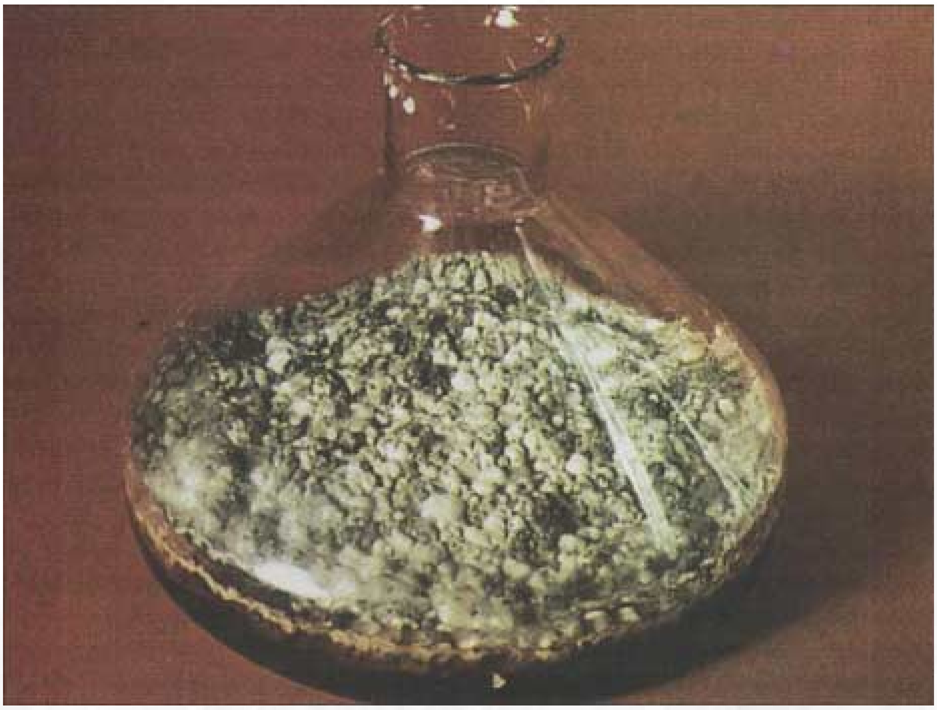

Figure 47 - Surface culture of ***Psilocybe semilanceata*** (with sclerotia formation).

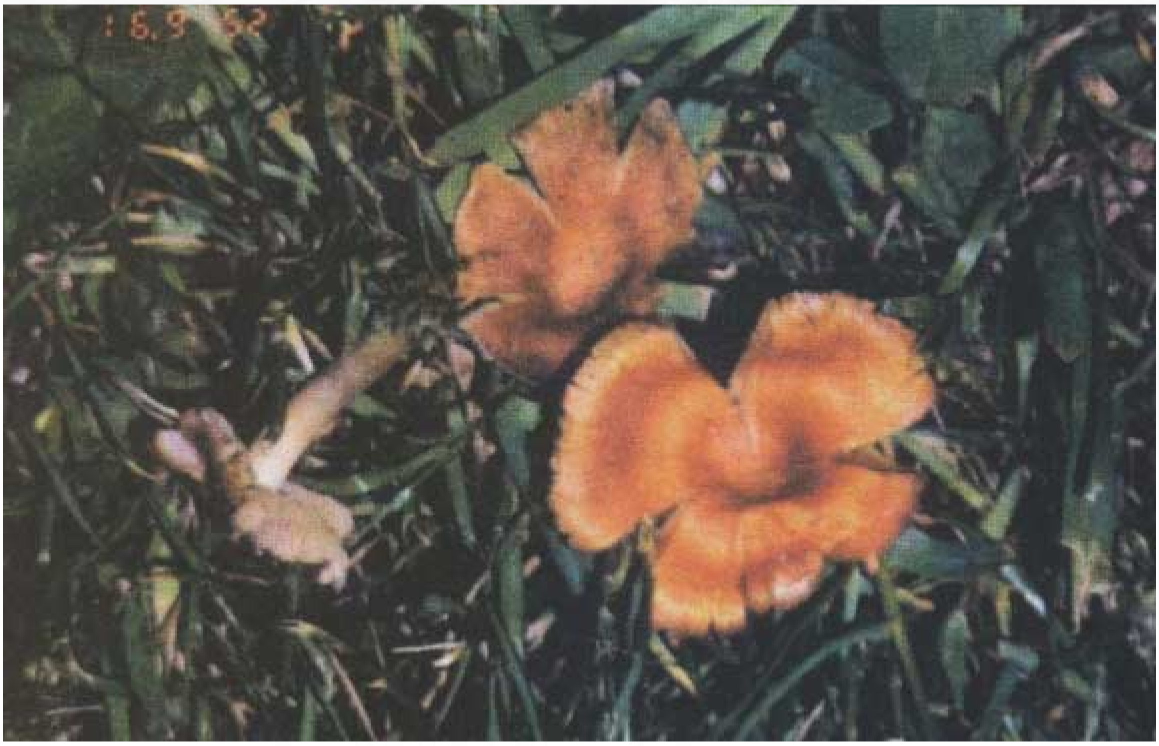

Figure 48 - ***Inocybe aeruginascens*** on grassy soil.

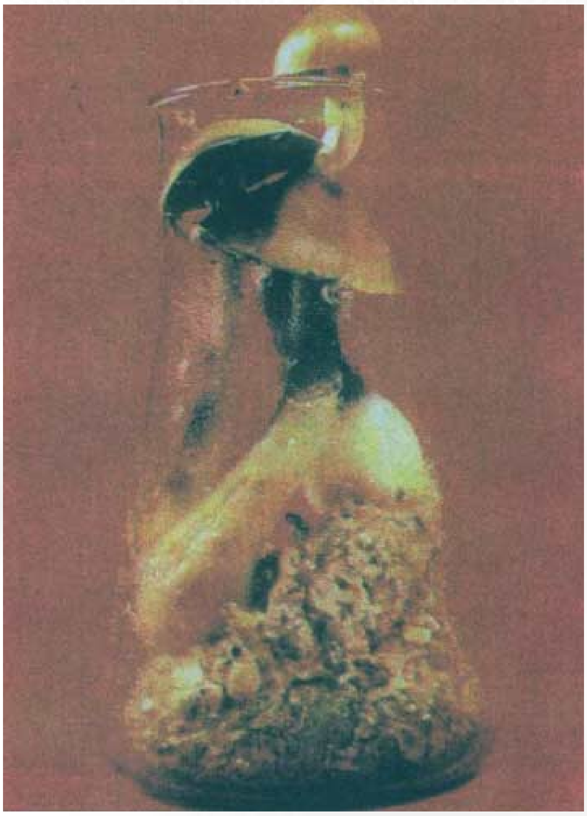

Figure 49 - ***Psilocybe cubensis*** on horse manure and rice.

It is safe to say that we currently know a great deal about the nutritional requirements of *Psilocybe cubensis*. To a lesser extent, such information is available about other species as well. Armed with this knowledge, future researchers may well discover new insights into physiology of these species, as well as the biochemical changes that occur during fruiting.

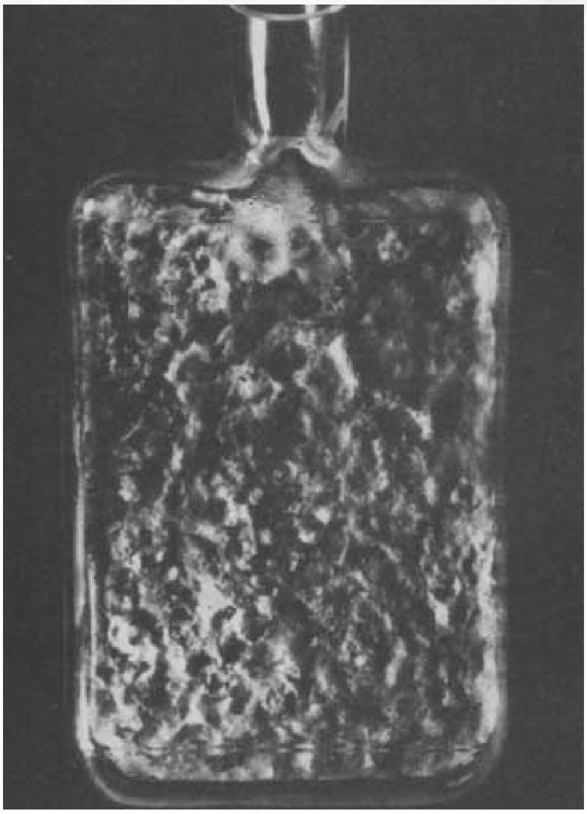

Figure 50 - Surface culture of ***Inocybe aeruginascens*** on a liquid nutrient medium.

In my experiments, it has already been established that the process of differentiation whereby mycelia are transformed into sclerotia or fruiting bodies is linked to increased production of psilocybin as well as psilocin, especially in *Psilocybe cubensis*.

Due to the relatively complex methodology and the type of equipment needed to isolate and maintain sterile cultures, it appears unlikely that cultivation of *Psilocybe cubensis* mushrooms by laypersons will significantly heighten the mushroom's popularity or widen its area of distribution anytime soon.

However, since the early 1980s, growing numbers of mycophiles in North America and Europe have successfully used "natural outdoor cultivation" to fruit *Psilocybe cyanescens* and similar species. This process involves selection of natural wood substrates striated with mycelia (rhizomorphs) that usually turn blue in response to handling. The mycelia are then transferred onto fresh wood chips or commercial mulch (not from cedar trees). After several months of growth, the mycelia fruit during the fall season.

7.1 - Spotlight on North America and Hawaii

In 1961, V.E. Tyler became the first investigator to report the detection of psilocybin in *Psilocybe pelliculosa* (Smith) Singer & Smith, a North American mushroom species. One year later, two research groups, working independently, discovered psilocybin, as well as psilocin, in samples of *Psilocybe baeocystis* Singer & Smith from the Pacific Northwest region of North America. Additional chemical and taxonomic findings on that region's mycoflora have been published up to the present day. This area includes the states of Washington (USA), British Columbia (Canada) and western Oregon (USA). The region is considered a major center of psychoactive mushroom use in North America. Some areas along the U.S. Gulf states have acquired similar reputations.

In 1966, Heim and his colleagues reported that an unknown *Psilocybe* species had been confiscated in Canada. The mushrooms appeared to be very similar to *Psilocybe semilanceata*. Shortly thereafter, A.H. Smith determined that the same mushroom species was popular among students in Vancouver. It wasn't long before *Psilocybe semilanceata* was recognized as a species quite common throughout the Pacific Northwest. Moreover, the mushrooms turned out to indistinguishable from European *Psilocybe semilanceata* samples.

The Spread of *Psilocybe semilanceata*

From the late 1960s onward, *Psilocybe semilanceata* usage increased, particularly in areas between the Pacific Ocean and the Cascade Mountains that range from Southern Oregon north to British Columbia. It is likely that during these years, Tom Robbins's popular book "*Another Roadside Attraction*" significantly contributed to the mushroom's increasing popularity. Today, *Psilocybe semilanceata* is the most widely used species in the Pacific Northwest, and its habitat is expanding into pasture lands east of the Cascade Mountains.

As in Great Britain, the mushroom is referred to as "Liberty Cap" in the United States. *Psilocybe semilanceata* has the reputation of being one of the most potent species without generally causing unwanted physical side effects (also see Chapter 3.1). As indicated in previous chapters, recurrent claims about different types of effects from different psychoactive species should be systematically studied, including comprehensive biochemical analyses. These research efforts will likely uncover new biodynamic ingredients.

Another factor that accounts for different types of effects is the variability in levels of alkaloid content. In the course of casual experimentation it is also not uncommon for a number of expectations to become self-fulfilling. The assumption that *Psilocybe baeocystis* (see Figure 72, p. 119), a strongly bluing species, causes a comparatively larger number of physical problems than other species is undoubtedly rooted in the mushroom's "reputation" as being the only *Psilocybe* species to date responsible for the only known fatality involving *Psilocybe baeocystis* - a child who died after eating some of these mushrooms (see Chapter 8 for more details on this incident).

Psilocybe baeocystis primarily grows in inland areas of the Pacific Northwest, on top of wood debris and on lawns in parks. It is a species that can often be found and collected on school and university campuses. *Psilocybe pelliculosa*, a mushroom mentioned in previous chapters, is a species also known as "Liberty Cap". Macroscopically, it is extremely difficult to distinguish from *Psilocybe semilanceata*. Unlike the latter species, however, *Psilocybe pelliculosa* will grow in forests on wood chips and sawdust.

Beug and Bigwood were able to furnish analytical proof in support of the claim that *Psilocybe pelliculosa* is weaker in its psychotropic effects than comparable species. *Psilocybe pelliculosa* contains about 30-50% of the amount of psilocybin found in *Psilocybe cyanescens* (slang names: *Blue wavy, Cyan, Grandote*), a species common across the Pacific Northwest. It fruits primarily in parks, forming partial fairy rings. This species did not become popular among users until the mid-1970s.

A New Psychoactive Mushroom

Several additional *Psilocybe* species have been found in the Pacific Northwest, even though the taxonomic classification of most of these species remains inadequate, despite the fact that monographs such as those by P. Stamets offer quite detailed descriptions of the psychotropic mycoflora. In the mid-1970s, Guzman and Ott reported a rather spectacular event concerning the spread of a "new" mushroom species. During the fall of 1972, large numbers of a strongly bluing gilled mushroom with a distinct ring pattern were found at the University of Washington in Seattle. The fruiting bodies were found growing on bark mulch, which came from a central distribution point and which had been spread widely across the campus by gardeners. Due to the bluing reaction, students at the university assumed that the mushroom contained psilocybin, a belief that was confirmed later on. The sudden appearance of massive numbers of fruiting bodies quickly inspired students at the university to use the mushrooms as a hallucinogen.

In my opinion, it is still uncertain if the mushroom really appeared spontaneously, or whether it fruited on bark debris simply because the substance had previously been mixed with spawn derived from fruiting bodies that originated elsewhere.

In any case, in 1976, the mushrooms were named *Psilocybe stuntzii* Guzman & Ott (slang name: "blue veil" or "stuntzees", (see Figures 54 and 71). Today, the species can be found growing on bark and on lawns in parks, on golf courses, football fields and gardens in numbers so large that it is considered the second most important species in terms of usage, after *Psilocybe semilanceata*. In addition, *Panaeolus subbalteatus* is another regionally important mushroom species (slang name: "red cap"), even though its users believe it to be slightly more poisonous than the *Psilocybe* species. Still, the mushroom is used quite frequently, because it begins to fruit during the spring. The *Psilocybe* species, on the other hand, do not appear until fall and continue to grow into early winter, when temperatures consistently drop below freezing, which inhibits further fruiting of the species. Under favorable conditions, only *Psilocybe stuntzii* can fruit year-round, even though this species still fruits most abundantly in the fall.

Mushroom Trips as a Popular Sport

In 1977, J. Ott estimated that several tens of thousands applied dosages of psychotropic mushroom material are harvested and used each year, particularly in the Pacific Northwest. Despite these quantities, there have never been reports of fatalities or serious physical damage as a consequence of using the *Psilocybe* or *Panaeolus* species. Local papers merely mentioned occasional panic reactions that subsided as soon as the acute effects of the mushrooms had worn off.

The usage of psychotropic mushrooms in the United States tends to cluster geographically in areas that are considered mushroom Eldorados. For example, the city of Redmond, WA used to be known as the "bicycle capital". Since 1978, several newspapers have renamed this city the "psilocybin capital".

Since the late 1960s, the usage of *Panaeolus cyanescens* and its closest relatives has become fashionable in Hawaii, even though the taxonomic differentiation of the *Panaeolus* species from each other is extremely difficult. There were initial attempts to preserve the fresh mushrooms by freezing them with dry ice (solid carbon dioxide) for export to the Pacific Northwest and Southern California. Apparently, these entrepreneurs were unaware of the fact that psychoactive ingredients will remain stable, as long as the mushrooms are dried and stored at temperatures below 50°C (122°F). Such export efforts were soon abandoned, because freezing the mushrooms turned them to mushy pulp that was difficult to transport. In addition, several local species had been discovered in the Pacific Northwest. During the early 1970s, fruiting bodies of the *Panaeolus* species preserved in honey began to appear on the black market in Hawaii and, on occasion, in North America. Again, this method fell short, because mushrooms could be preserved for only short periods of time.

Panaeolus subbalteatus grows in several areas in the Hawaiian Islands, but it is used less frequently than other *Panaeolus* species. Even though one often hears about "Hawaiian strains" of *Psilocybe cubensis*, the species is not native to The Islands and should grow there only under conditions of artificial cultivation. Any spawn used for cultivation, however, must have been isolated from fruiting bodies that originated elsewhere. In Hawaii, the extent of adverse reactions was also limited to a few panic reactions observed in recreational users who had ingested mushrooms of the species *Panaeolus cyanescens*. In 1972, an apparent fatality was definitely not caused by ingestion of mushrooms, but instead was most likely the consequence of a heroin overdose, as reported by J. Allen, who has researched this incident extensively.

The legislatures in North America and Hawaii do not pay very much attention to the usage of psychoactive mushrooms. The identification of species is often quite difficult, so that police enforcement activities primarily target misdemeanors such as parking violations and the willful destruction of fences around pastures. The latter is not uncommon during attempts to force entry into areas where *Psilocybe semilanceata* can be found.

In December 1979, the High Court of British Columbia ruled that the Canadian Narcotics law prohibits psilocybin only in its pure form, whereas mushrooms containing the alkaloid as a natural ingredient are exempt from the law. This decision seems both realistic and reasonable, considering the substantial, uncontrollable spread of these mushrooms and an ongoing battle against truly addictive drugs that requires all available efforts and resources.

Even though the extent of prosecution of drug law violators in Canada and the U.S. varies from state to state, psilocybin-containing mushrooms are only a minor factor in the overall "war on drugs". In California, however, mushroom cultures are illegal, as well as spore prints (!) from the *Psilocybe* species. Spore prints, however, are impossible to control. *Psilocybe cubensis* is common across the South, and *Panaeolus subbalteatus* grows across the Southwestern U.S., where the mushrooms are used extensively. By one estimate, there were 100,000 "Magic Mushroom People" in the state of California alone, a number likely to be much higher today. The demand created by this growing market is probably being met through cultivation of *Psilocybe cubensis*. These users ingest psychotropic mushrooms as a form of recreation, or incorporate them in the ritual practice of natural mysticism. Other users prefer mushrooms as an aid to meditation or to attain communication with the realm of the divine. Regardless of motivation, users tend to lead secluded, self-sufficient lives in close proximity with Nature. Across North America, the total number of magic mushroom consumers is likely close to one million, quite possibly higher.

By the early 1980s, prominent experts in the field had estimated that the number of hallucinogenic mushroom users in the United States outnumbered LSD users for the first time, a trend that went hand in hand with a rise in environmental awareness. In this context it is interesting to note that the Drug Abuse Warning Network (DAWN), which collects data from throughout the United States, documented only 31 cases of clinical interventions for usage of psilocybin-containing mushrooms in 1982. In some of these cases, the mushrooms were used in combination with other substances, confusing the pharmacological picture. In comparison, LSD was involved 1,498 times, while marijuana was cited in 5,295 cases. It should be noted that the high number of marijuana cases cited appears inflated and suspect, in light of data from other studies.

It is interesting to note that T. Leary's psilocybin experiments during the early 1960s provoked severe reactions of a moralistic-puritan nature, while medical reports about prolonged psychoses and other such side effects did not appear until the "LSD era" some years later.

North America's mushrooms offer many opportunities for additional taxonomic work and many more still remain to be discovered. To illustrate, a new mushrooms species was recently reported from Oregon. The mushroom, *Psilocybe* azurescens Stamets & Gartz is unusually large and very potent due to its high psilocybin content. North America's rich mycoflora, particularly in regions of wet climates in the eastern and midwestern United States is wide open for further research efforts that may well yield valuable and amazing new results.

As early as 1909, Murrill described "*Inocybe infida*", a mushroom with "narcotic" effects from New York. In 1911, Ford named "*Inocybe infelix*" as a species that also caused strange effects, without inducing symptoms of muscarine poisoning. These descriptions immediately bring to mind the psilocybin-producing fibreheads, even though visionary experiences are not expressly mentioned.

In the future, we should expect an increase in usage of local, psychoactive species from locations across the U.S. and Canada.

7.2 - Mycophilia in Central and South America

Compared to the time of Wasson and Heim's discovery, recent decades have brought significant changes to several regions of Mexico in terms of how local Indians relate to the psychotropic *Psilocybe* species. In many remote parts of the country, mushroom cults still exist in their specific contemporary forms which combine Christian views with elements from pagan and pre-Christian Nature religions.

By contrast, in other parts of the country, mushroom rituals have fallen into disuse in the wake of interaction with Mexico's "modern life" and its tourism industry. When Guzman investigated the taxonomy and geographic distribution of *Psilocybe aztecorum* Heim in 1978, he noted that several active "curanderas" had been the focal point of sacred mushroom worship 20 years earlier. Today, the next generation of Indians no longer ingest the mushrooms and consider the hallucinogenic species to be nothing but a popular trading commodity for Western tourists.

Starting in the 1960s, large numbers of young people from industrialized nations ("hippies") began to visit the centers of mushroom worship as tourists, favoring the state of Oaxaca. They came mostly from the United States, and initially their main destination was the village of Huautla de Jimenez, to visit Maria Sabina, who guided R.G. Wasson during his first mushroom session in 1955. To the extent that magic mushrooms have been labeled "fool's mushrooms" or "joker's mushrooms" in Europe, it is interesting to note here that Maria Sabina herself repeatedly referred to the mushrooms as "clowns" and called herself "chief of the clowns" or "lord of the clowns". In Mexico, magic mushrooms are also known as "mushrooms of pure laughter".

Today we know that this run on Mexico's mushrooms helped destroy the cultural identity of the native Indians, causing discontent and rising crime rates in several villages. Self-appointed "curanderas", with no traditional roots, presided over mass ceremonies with magic mushrooms. Participants who had panic reactions did little to ease tensions among the local population. Finally, the police and the army were called in to put an end to the resulting turmoil. Mushroom tourism in Mexico dropped off rapidly, especially after similar species were discovered in other countries. Despite legal prohibitions, however, various *Psilocybe* species are still being sold to tourists in some areas of the country today. This phenomenon is not limited to Mexico. In the mid-1970s, Lowy reported from Guatemala that Indian children near the capital city were offering *Psilocybe mexicana* Heim for sale to foreigners, a trading practice that has been observed in other parts of the country as well.

Experts on bluing gilled mushrooms, who traveled to South America and the Caribbean, discovered several psychotropic species (e.g. *Panaeolus cyanescens* in Jamaica), even before mycological research established the existence of these species. According to those few scientific publications on taxonomic identity, the two most commonly used species are *Psilocybe cubensis* and *Panaeolus cyanescens*. Around 1970, tourists who had previously been looking for *Psilocybe* species in Mexico learned that they are abundant among Colombia's mycoflora as well. Consequently, knowledge about these mushrooms spread quickly among Colombian youngsters, possibly as a result of Central America's Indian tradition. Thousands set out in search of these species in and around their areas of residence. Special communes were formed, situated in idyllic regions of the Andes Mountains. The most famous among them was known as La Miel ("honey"). *Psilocybe cubensis* and the *Panaeolus* species were also found to be common across those regions of Amazonia where Colombia, Peru and Brazil share common borders. The archaeological park at San Augustin near Bogota has been dubbed "heart of the magic mushroom land". These species have also been used in Peru. During the 1980s, road side signs proclaiming "No To San Ysidro Drugs!" were a common sight. The slogans referred to *Psilocybe cubensis* under an old name. South America's problems, however, cannot be solely blamed on the ingestion of indigenous, non-lethal mushrooms. Socio-economic problems are rooted in poverty and destitution, epidemics, civil warlike conditions in some parts, as well as the rampages of the cocaine mafia. Today, Argentina and Brazil are two countries where magic mushroom use is still common. In 1975, Pollock reported the practice of mixing a drink from milk, honey, bananas and magic mushrooms.

In terms of interdisciplinary research in Central and South America, there remains the vast challenge of uncovering additional clues about ritual usage among early cultures, coupled with efforts to trace and analyze more recent kinds of uses. Chapter 3.5 already included one historic account of magic mushroom use several centuries ago. A large number of golden pendants in a variety of mushroom shapes have been found in

Colombia, suggesting that magic mushrooms have been used there for centuries. At the same time, research into the taxonomy and chemistry of South American psychotropic species has barely just begun.

7.3 - Australia's Mycoflora Attracts Attention

In 1934 J. Cleland publicized the existence of 12 mushroom species of the genus *Psilocybe* in South Australia. Up to that time, there had been no accounts about psychotropic intoxications from the fifth continent.

Cleland was probably the most renowned Australian mycologist of the 20th century. As early as 1927 he had already described a new species named *Psilocybe* subaeruginosa. This mushroom grows in New South Wales, Victoria and South Australia and turns bluish-green with age or in response to pressure. During the 1940s several accounts surfaced which detailed a series of "hysterical psychoses" caused by *Panaeolus ovatus* Cke. & Mass. (also see Chapter 3.3).

In 1958, Aberdeen and Jones described the geographic distribution of *Psilocybe cubensis* across the southeastern valleys of Queensland and New South Wales. They speculated that this was the mushroom responsible for the cases of intoxication, not the *Panaeolus* species. They proposed this hypothesis, because the mushrooms in question were thought to have been champignons, who resemble the fleshy *Psilocybe* species much more closely than any of the *Panaeolus* species. In addition, the *Psilocybe* species had been described as being much more common in the area. Under wet climate conditions, the *Psilocybe* species can be found growing in abundance on cattle dung, especially along the sunshine coast of Queensland, in the open valleys around Brisbane and in areas that used to be rain forests, but have now been transformed into pastures. It is quite likely that the species was brought into the country by its early settlers. It wasn't until the early 20th century that land in Australia's subtropical and tropical regions was converted into pastures.

Today, it is generally thought that the mysterious *Panaeolus ovatus* species was, in reality, *Panaeolus cyanescens*.

It wasn't until the early 1970s that the latter species was identified. Soon after, the *Panaeolus* species were recognized as being very common throughout Northern and Southern Australia.

Despite the widespread geographic distribution of psychotropic species in Australia, there were only a few efforts to publish information about their chemical composition. In 1970, Picker and Rickards reported the isolation of 0.45% of psilocybin from dried fruiting bodies of *Psilocybe* subaeruginosa, but failed to find any psilocin in that sample. Later on, other authors reported only about one-tenth of this amount of psilocybin, a number that I believe to be too low, considering reports about the mushrooms' strong psychoactive effects.

Psilocybin was also found in Australian samples of *Psilocybe cubensis* (see Figure 2, p. 5), while *Panaeolus cyanescens* was reported to contain psilocybin, along with even higher levels of psilocin and serotonin as well.

Starting in the late 1960s, popular, widespread usage of psychotropic mushrooms began to catch on in Australia. At the same time, these accounts of mushroom use were the only comprehensive reports that originated in a country other than Mexico.

In the summer of 1969, a 4,000-hectare-region near the coast of Queensland gained notoriety because of its *Psilocybe cubensis* crop that grew there after the rainy season. Interested collectors flocked to the area in droves. Media reports at the time gave the impression that the mushrooms were an entirely new discovery, completely disregarding Central American traditions. *Psilocybe cubensis* conquered the black market, where the mushrooms were sold for about U.S.$1 per fruiting body. In the wake of an above-average rainy season, the species fruited so abundantly that special transportation companies were founded for delivery of the mushrooms to Australia's large cities.

However, even here the mushrooms did not grow in heaven: the epidemic subsided somewhat, and the usage of psychotropic mushrooms became endemic across all of Australia. On May 8, 1971, the governor of the conservative state of Queensland prohibited possession of *Psilocybe cubensis* and the species fell under the same legal guidelines as *Cannabis sativa* (hemp) and *Papaver somniferum* (opium poppies).

Still, usage of the *Psilocybe* species continued, despite harsh penalties for possession and use (a total of 74 individuals were sentenced in 1972, and 27 in 1973).

Also, those interested in mycological field research continued to study *Psilocybe* subaeruginosa and even discovered the species in the northern part of the country. Like *Psilocybe cubensis*, this species is also known by the colloquial name of "gold top", whereas *Panaeolus cyanescens*, a species that wasn't discovered until later, acquired the nickname "blue meanies" within the counterculture (an expression that refers to a collection of several fruiting bodies). It is likely that these mushrooms were named after the small blue men featured in the classic psychedelic Beatles movie "Yellow Submarine", which was released in 1968.

In colloquial Australian English, "mushies" is a commonly used short form for "mushrooms".

Next to fresh mushrooms, "processed" preparations also began to appear on the black market: In Hobart, Tasmania, for example, dried and ground up mushrooms packaged in gelatine capsules were sold for $6 a fruiting body. The availability of mushroom-based hallucinogenic substances drastically reduced the market share of LSD, which was generally a lot more expensive. By 1972, LSD had almost disappeared from the black market.

Based on Southcott's (1974) writings, it is likely that the unpleasant taste of fresh specimens of *Psilocybe cyanescens* was the main reason for the processing of the fruiting bodies.

Bizarre Reactions

Considering the widespread use of psychoactive mushrooms in Australia, there were only a handful of reports about medical complications, amounting to only minor complaints from a few individuals. Symptoms were almost exclusively limited to panic reactions due to excessively high doses. These reactions were precipitated by bizarre psychic sensations, which the person was unable to integrate. *One 17 year old teenager, for example, developed a panic reaction when she suddenly felt like a banana that was being peeled* (Southcott). In all cases, symptoms disappeared within several hours as the psilocybin wore off. While a few cases included complaints such as stomach cramps and kidney pain, these symptoms are not characteristic of the *Psilocybe* species and their relatives. It is likely, that other, poisonous, mushrooms, such as muscarine-producing species, were to blame for these syndromes.

I would like to close this chapter with a report from an Australian mushroom lover, who illustrates the reasons and circumstances of psychoactive mushroom use in Australia (Southcott).

Report about the effects of a "gold top " mushroom:

> *The mushrooms which were prepared in a broth and boiled for about two minutes may be used to induce an extremely powerful hallucinatory trip. When eaten raw, the effects can take up to two hours to come on, but taken in soup form they can begin to occur within five to ten minutes of being eaten. The first noticeable effect is a tingling sensation from head to toe, followed by extreme warmth or cold throughout the body. Mild hallucinations begin to occur within a quarter of an hour and become stronger as the trip reaches its peak. This peak can be a terrifying experience for the novice; individuals may not know what to expect and may believe they have gone insane. In many cases, this "insanity" can also be pleasurable and can cause a person to lose all fear of things which had previously seemed impossible to bear. Everything material and otherwise is laid out in front of you for examination and nothing is beyond human comprehension. In my opinion and experience, these mushrooms, when used by persons capable of understanding the tremendous power contained within them, can only be beneficial in their effects.*
>
> *I have found them (Psilocybe subaeruginosa - Southcott) growing in flatbottomed valleys and on gentle slopes. They thrive in moist, grassy soil and can range in size from a quarter of an inch up to two or three inches in diametre. In regard to an overdose of these mushrooms, this user feels that it is not really an accurate term for this condition. It is more an extreme fear of certain things or people that causes "freak-outs". The trip can change from one of fear and hysteria to one of pure ecstasy in a matter of a second, if a person is treated correctly. The police, in my opinion,*

> *are the cause for more bad experiences than all other factors combined. I myself have almost lost all fear of everything I previously dreaded. I intend to continue the use of these mushrooms and see where it leads me, whether it be a good (lawful) or bad thing....*
>
> *Description: The mushrooms (Psilocbe aeruginosa Southcott) have caps colored yellow to dark brown on top, and cream-colored to almost yellow underneath. If picked fresh, the stem and parts of the cap will turn green and blue or sometimes violet. This discoloration does not occur until after the mushrooms have been picked.*

7.4 - European Customs and Conventions

The first report ever published in a scientific European journal about usage of *Psilocybe semilanceata* in Europe was written by M. Carter and appeared in *New Scientist* in September 1976.

"Mushrooms Are Mushrooms"

The mushrooms quite suddenly emerged in the spotlight of public attention in 1976, when Judge Blomefield of Great Britain's High Court handed down a verdict of "not guilty" in the trial of a man accused of possession of psilocybin in the form of dried fruiting bodies from the species *Psilocybe semilanceata*. According to Carter's report, the acquittal was justified as follows: "*Psilocybin is a chemical and mushrooms are mushrooms*". In the wake of this decision, however, a few individuals in Britain were nonetheless sentenced for possession of psilocybin, because the British legal system is based on the principles of common law, which means that the High Court decision was not necessarily binding in cases that went to trial in lower courts after the man had won his acquittal in the High Court.

Despite its Celtic ancestry and the practice of Nature religions, England is among those countries whose population has traditionally been quite mycophobic in its attitudes toward mushrooms, which have always been thought of as poisonous, slimy and moldy. It is therefore quite remarkable that these values appear to be changing with the current younger generation. Could it be that England's Celtic heritage is making a reappearance after centuries of dormancy?

In 1978, C. Hyde and his collaborators reported several cases of voluntary intoxications with *Psilocybe semilanceata* from a medical perspective, describing symptoms experienced by mushroom collectors that range from typically visionary experiences to the manifestation of acutely delirious states. The authors emphasized that the mushrooms were well-known within the hippie subculture of Manchester. Thirty to forty *Psilocybe semilanceata* mushrooms were considered an appropriate dose to attain a fully hallucinatory state.

According to British users, the effects of *Psilocybe semilanceata* include intense visuals without any of the negative feelings that may be caused by LSD. British colloquial names for the mushroom are quite poetic, such as:

- Liberty Cap
- Magic Mushroom
- Blue Legs
- Pixie Caps

Contrary to common opinion, "liberty cap" is not a new name, since M.C. Cooke mentioned it in his writings that date back to the 19th century.

Due to the widespread distribution of this *Psilocybe* species across England, particularly Scotland and Wales, *Psilocybe semilanceata* appears to be more popular in England than in any other European country, with the possible exception of Norway. This is an opinion echoed in numerous scientific and medical articles published on the subject in Great Britain. In my opinion, these publications contain the most detailed descriptions of casual use of psilocybin-containing mushrooms species by laypersons anywhere in the world.

One analysis by P.R. Mills and his collaborators described seven Scottish patients with symptoms caused by ingestion of *Psilocybe semilanceata* mushrooms during the fall of 1978, when the species fruited abundantly in the Glasgow area after heavy rainfall. Four of the seven men had eaten no less than one hundred mushrooms each, which meant they had taken about 50 mg of pure psilocybin a person. It is not surprising, then, that such dosages should cause visions that lasted several hours, along with marked somatic symptoms.

Mega Mushroom Festival

While there is talk about "hippies" in the report from Manchester, a 1980 newspaper article from Wales describes a "new kind of gypsy", whose exploits included a mushroom celebration near Cardiff with 100 participants. The occasion was the discovery of yet another bumper crop of *Psilocybe semilanceata* in that area. Nineteen of the revelers felt so seriously ill they had to seek medical treatment.

It appears that in the early days of mushroom usage in Great Britain, massive amounts of *Psilocybe* mushrooms were consumed on several occasions, which caused a higher number of panic reactions than elsewhere in the world.

However, it is clear from articles published in medical journals that these cases were merely "the tip of the iceberg", that is, they were a small group of users whose reactions to the acute stages of mushroom intoxication attracted attention because they included clinically relevant symptoms such as states of pathological depression with no recognition of surroundings.

In an attempt to describe patterns of usage of the *Psilocybe* species in the Tayside area near Dundee, Scotland, N.R. Peden and his collaborators found that the typical user was much younger there than in Manchester or Wales. The authors examined 27 patients, whose ages ranged from 12 to 24 years. I have previously cited accounts about accidental intoxications indicating that children can have abnormal reactions to psilocybin, such as cramps or loss of consciousness. Teenage use of hallucinogens and other psychoactive substances, including alcohol and nicotine can have disastrous consequences.

The results of a survey at two Scottish schools of 59 children aged 14 to 15 years revealed that 66% of them had already heard about the mushrooms' effects. Also, a paper published by R.E. Young and his research team in 1982 found that the mushroom users in the Glasgow area as a group are quite young. In 1981, these researchers treated 49 children and adults aged 12 to 28 years. These authors are correct in pointing out that the mushrooms cannot be eradicated due to their large area of distribution. At the same time, however, they demand that fungicides be sprayed on mushroom fruiting areas that are easily accessible!

This is a baffling and incomprehensible proposition - to acutely endanger all residents of a certain area by exposing them to poison, simply because there were a few mild cases of mushroom intoxications, with symptoms that soon disappeared. If anyone is to blame, it is the users for their carelessness and recklessness. Fortunately, these crypto-schizophrenic proposals were never implemented.

On the other hand, there are interesting statistics available from the poison center in London, about reported cases, where medical attention was required following ingestion of *Psilocybe semilanceata*. The numbers below show how many people received therapeutic treatment in Great Britain in a given year:

1978 - 33
1979 - 47
1980 - 96
1981 - 142

The average age of the mushroom collectors was between 15 and 19 years. Reports mostly came in during September and October of each year, which corresponds to the mushroom's fruiting period. Cases that were reported during other months of the year had been caused by ingestion of dried mushroom material.

In 36% of these individuals, the mushrooms caused significant visual distortions and visions. Five people acted aggressively without experiencing perceptual alterations. Dosage varied from half a mushroom (effects?) to up to two or three pounds. If the latter amounts have been reported truthfully, those individuals ingested about 1 to 1.5 g of pure psilocybin, assuming an alkaloid content of 0.1% in fresh mushrooms. However, in cases where whole mushrooms had generally been eaten according to the Mexican tradition, liquids removed via stomach pumps largely contained whole mushrooms. Failure to carefully chew the mushrooms before swallowing means that only a fraction of the available amount of alkaloids is extracted from the mushrooms and absorbed by the body.

Panic Reactions

In cases when intoxications were caused by eating 'normal' amounts of mushrooms and the ingestion of potentially deadly species could be excluded, pumping the patients' stomachs turned out to be a procedure that was both too drastic as well as unnecessary. In younger, hyper-suggestible patients, the procedure can precipitate extremely aggressive behavior. In addition, it often doesn't work, because the mushrooms tend to clog the pumping apparatus.

Therefore, panic reactions after ingestion of *Psilocybe semilanceata* is a condition that, in some cases, may be aggravated or even induced by improper treatment of the patient at hospitals and clinics. After evaluation of the statistics on *Psilocybe semilanceata* usage in Great Britain, J. Francis and V.S.G. Murray emphasize that there has not been a single fatality among some 318 poisoning cases - in fact, no severe somatic symptoms were noted, nor have there been incidents of misidentification of the mushroom species. According to the authors, intoxication can be a quite unpleasant experience for the individual. Panic reactions pose the only significant hazard, which may endanger the individuals as well as their surroundings for the duration of the mushrooms' effects.

As an ideal treatment, they proposed that patients be moved to a darkened, beautiful room, and that they be watched until the effects have subsided. If necessary, tranquilizers such as diazepam should be administered.

R. Watling mentions a non-fatal case in Scotland, where *Inocybe geophylla* (Sow. & Fr.) Kumm., a muscarine-containing species, had been mistaken for the *Psilocybe* species.

In the 1980s, *Psilocybe semilanceata* was named as the mushroom species that caused by far the largest number of intoxications in Great Britain. Today, usage of this psychotropic species in that country is not quite as popular anymore as it was 10 years ago. Also, mushroom eaters are no longer prosecuted.

By comparison, a short report by a medical student from Manchester was not convincing. The report claimed that a 24-year old patient suffered from severe depression with somatic side effects for three months ("persistent psychiatric symptoms") and that these symptoms had been induced by ingestion of *Psilocybe semilanceata*. At the time, the patient was experiencing personal stress and had also taken other substances as well. Despite the wide distribution of psychoactive mushrooms around the world, there have been no reports of similar episodes.

The usage of *Psilocybe semilanceata* in Norway was first described during the fall of 1977, in Sandnes, near the Rogaland area. Up to that time, the Norwegian literature had depicted *Psilocybe semilanceata* as merely a small, inedible mushroom known to grow in grass interspersed with other, similar, species. Apparently, the experiences in England and the United States inspired the use of these mushrooms in Norway, as well as in other European countries. However, it is also possible that a report published in 1976 about the discovery of psilocybin in Norwegian collections contributed to subsequent usage of the mushrooms.

Knowledge about the mushrooms spread quickly around Norway, especially in the fjord areas, were the species fruits most abundantly. Daily and weekly papers as well as underground magazines dealt with the mushrooms at length. Only a small number of panic reactions were known to have occurred in Norway, with some individuals requiring temporary clinical attention. Nonetheless, in December 1981, the mushroom species was classified under Norwegian narcotics law as an "absolutely forbidden substance". The same classification applies to the potentially dangerously addictive drugs of the heroine type, as well as to the pure hallucinogens, such as LSD, mescaline and psilocybin, all of which are pharmacologically completely different from any of the heroine-type drugs. By contrast, Figure 57 illustrates that other European nations have attitudes similar to those found in British Columbia, which form the basis for my own analytical work with mushroom materials.

Compared to Norway, there is less information about usage of *Psilocybe semilanceata* from other countries. The year 1981 has been named as the starting date of usage in Finland; by 1984, there had only been one patient who required medical attention.

There are additional countries where the mushrooms are being used and collected, more or less sporadically: The Netherlands, Austria, Denmark, Sweden, Belgium, Germany, Switzerland, and recently Russia near the St. Petersburg area. The mushrooms have even been found in Siberia. In some areas, where the mushrooms thrive in abundance, a more comprehensive mode of usage can be observed, without attracting much additional attention over a longer period of time.

Costly measures, such as the deployment of helicopters over pastures in the Jura Mountains of Switzerland to flush out mushroom collectors have rarely been used and were quickly abandoned.

Switzerland is another country where *Psilocybe cubensis* is being cultivated and used without attracting much attention. Below is an account provided by a Swiss friend about his first ever experience with this species:

> *Intense, kaleidoscope-like colors are being generated. I begin to dive in and out of other realities, followed by the painful loss of ego, death and life. Suddenly I find myself inside a wooden box. My body is a black mass full of low-level pain. I have the black plague. I was put inside the box, because I was thought to be dead, but I am still alive. I am being carried to and placed on top of cart so that I can be transported to be burned. Few others are being given such a box. At first I am in despair, but then I know that the end is near, anyway. Death is a liberation for me. I remember: I see my house in the city center of Metz, where I used to live until now. Then came the plague. My years of selfish dedication of helping sick, degenerate, stinking, hungry and dying people.*
>
> *I provide comfort and companionship, as well as medication that remains ineffective. I continuously make house calls, there is no end in sight. I become ill myself. At first I deny this fact, but now I am inside this wooden box, in a state of semi-consciousness. I know that the end is here.*
>
> *I know that I am a physician named Claudius Vinzen and that the year is 1427.*
>
> *I wake up in the reality of winter, 1990. Metz, where is Metz? Later on, I locate the city on a map of France and until this day, I have been trying to verify if this physician lived there during the Middle Ages. I am reminded of my long years of professional work with criminal and drug-addicted youngsters. I sense the common elements of these two realities (karma?), the sacrifices of selfless helping.*

Such deeply moving experiences do not appear to be unusual (compare to reports of experiences with *Psilocybe semilanceata* in Chapter 3.1) and should always be studied in all seriousness.

Only France seems to engage in elaborate activities designed to locate collectors of psychotropic mushrooms. Despite its grand mycological traditions, France is a country that has a rather absurd prohibition against the exhibition of *Psilocybe* and *Stropharia* species (European *Stropharia* species do not produce psilocybin) at scientific conventions. As a consequence, French mycologists have been avoiding the use of the genus *Psilocybe*. Nowadays, at mycological conventions, *Psilocybes* are exhibited under the old name of *Geophila* (Quelet), which appears to have gotten around the problem of breaking the law.

According to my personal communications with mycologists, the usage of *Psilocybe semilanceata* in Italy began in about 1980/1981 and has been rising steadily since then. At the same time, there have been no clinically relevant cases, nor any legislative action on the matter. Towards the late 1980s, usage of psychoactive *Psilocybe* species began in the former Czechoslovakia, for instance, around the region of Brno. It appears that *Psilocybe bohemica* is used more often in this country than *Psilocybe semilanceata*, as the former species is quite common there.

Very little is known about European usage of mushroom species from other genera. In the mid-1980s, Spanish youngsters near Barcelona were observed using *Panaeolus* mushrooms.

The well-known booklet authored by Oss and Oeric about the cultivation of *Psilocybe cubensis* has been translated into several European languages and published in different countries. It is almost certain that the book is being used as a cultivation guide in Europe, however, there are no available data about the success rate of these experiments. In many cases, commonly occurring contaminants probably prevent fruiting of this subtropical species on rye substrate.

I won't risk making predictions about the extent of future usage of indigenous European psychoactive mushroom species, nor am I able to predict which species may or may not gain in popularity. However, it is possible to speculate that the increased geographic distribution of species such as *Inocybe aeruginascens* and *Psilocybe cyanescens* may lead to more unintentional intoxications, which, in turn, may result in creating a generally deeper knowledge base about the attributes of these mushrooms.

Senefelderstr. 26

In Beantwortung Ihres Schreibens vom 15.12.1982 erlaube ich mir Ihnen die 5. Durchführungsbestimmung zum Suchtmittelgesetz zu übersenden, in der bereits einige der von Ihnen aufgeworfenen Fragen berücksichtigt sind.

Danach werden Festlegungen für "Cannabis", Papaver bracteatum und Papaver somniferum getroffen.

Gesetzliche Regelungen für den Cocastrauch sind nicht im Gesetz enthalten, da dieser bei uns weder wildwachsend vorkommt noch angebaut wird. Ebenso ergab sich bisher keine Notwendigkeit für gesetzliche Regelungen für Lophophora will. oder Psilocybe mex., für die es auch keine Regelungen in den internationalen Konventionen gibt.

Ich hoffe, Ihnen mit der Beantwortung Ihrer Fragen geholfen zu haben.

Mit kollegialen Grüßen

PhR Dr. rer.nat. E.-M. Schneidewind
- Leiterin des ZSB -

Figure 57 - A letter from the "Central Bureau of Substance Abuse" in the former East Germany, detailing some legal restrictions on psychoactive plants. At the time (1983), ***Psilocybe mexicana*** was not a controlled substance and no restrictions applied to its use.

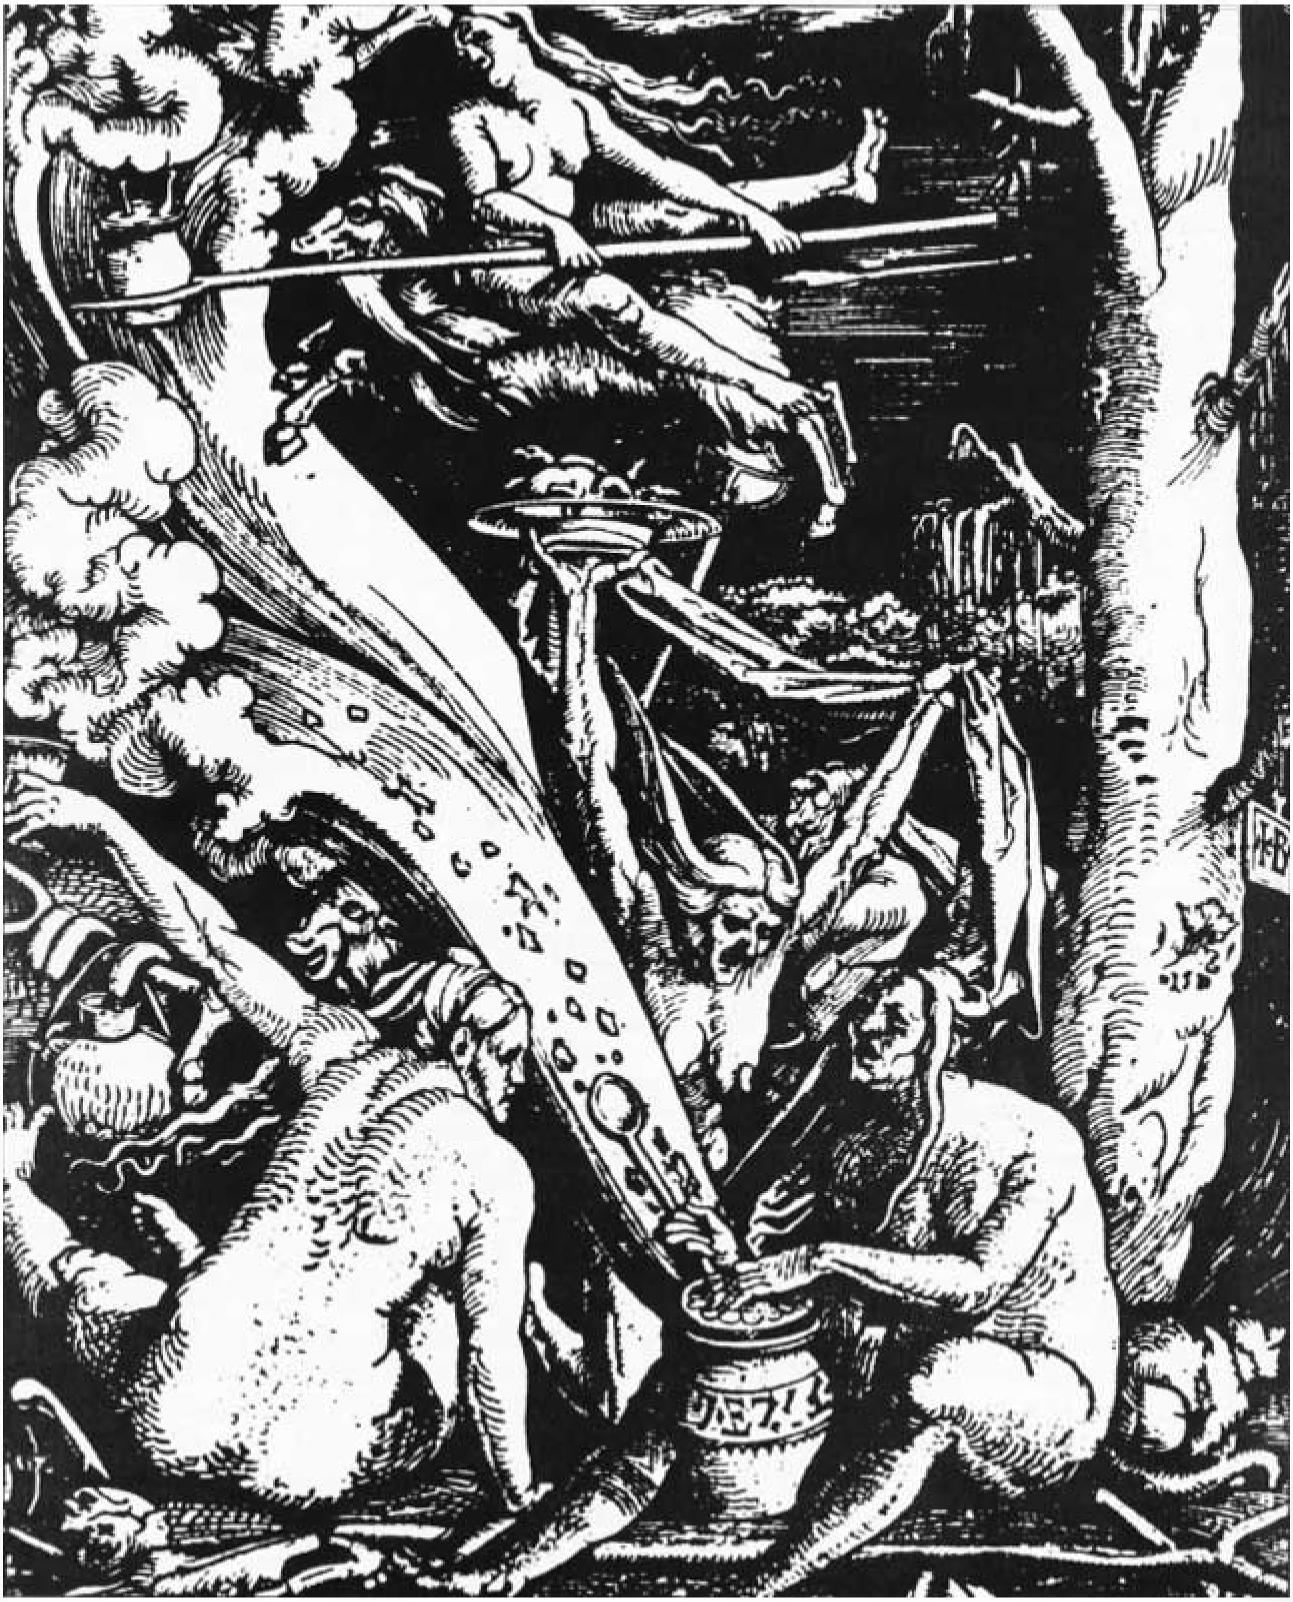

Figure 58 - Woodcut entitled "Cooking Witches" by Baldung Grien (1514). Such cultural practices undoubtedly included familiarity with psychotropic mushrooms, even though such knowledge was considered pagan at the time. The practice of "witchcraft" was maligned and accused witches were persecuted, tortured and executed, as the Christian Inquisition was desperate to suppress pagan beliefs and wisdom.

7.5 - Japanese Experimentation

Mushroom species containing psilocybin are also found in Japan. Tales about the infamous "Laughing Mushroom" date as far back as the Middle Ages. An account from the 11th century became famous:

> *Several lumberjacks from Kyoto got lost in the woods for reasons that remain unknown. Suddenly they encountered four or five Buddhist nuns, whose behavior did not at all conform to expectations: instead of immersing themselves into their inner selves in a quiet quest for Nirvana, the search for Absolute Nothingness, these daughters of Buddha were found dancing and laughing. It turned out that the nuns had also gotten lost in the woods and dealt with their hunger by eating some delicious mushrooms. The faithful nuns soon discovered, however, that they could not stop dancing and laughing. The lumberjacks's stomachs, in the meantime, had also begun to growl and, thinking that what was good for the nuns was good enough for them, the lumberjacks ate some of the mushrooms as well. Soon after, they also succumbed to overwhelming fits of laughter and the urge to dance....*

The linguistic moral of the story: since that time, the mushrooms in question have been referred to in Japanese as

- "maitake" (Dancing Mushrooms)
and later on
- "waraitake" (Laughing Mushrooms).

For a long time, the species thought to be responsible for these symptoms were identified in the mycological literature as *Panaeolus papilionaceus* and as *Gymnopilus spectabilis* ("giant laughing mushroom"). However, today we know that the former is a species from Europe and North America which does not contain any psychoactive substances, while even Japanese authors have been unable, since 1980, to confirm the existence of psilocybin and its derivatives in the latter *Gymnopilus* species. Only inactive substances have been found in *Gymnopilus spectabilis*.

In Japan, the investigation of these mushrooms has a long tradition: There is evidence that mushrooms have been cultivated in Japan for no less than 2,000 years, by collecting naturally grown mycelia of *Lentinus edodes* (Berk.) Singer and transferring onto pieces of wood selected to serve as new substrates.

Incidentally, literary sources from China also attest to knowledge about mushrooms from that country, where such mushrooms were said to be the cause of a (temporary) "disease of dry laughter".

Still, the reports about an irresistible urge to dance constitutes a rather unusual effect of psilocybin, from our current point of view. While psilocybin is initially known to cause fits of laughter, this phase is generally followed by a state of relaxation and a drop in levels of physical activity. It is likely that, in this case, medieval Japanese mentality was a cultural factor that modified the specific expression of an altered state of consciousness.

Aside from the two disputed mushroom species mentioned above, several psychoactive *Psilocybe* species can be found in Japan. There are several known cases of accidental ingestion that occurred during the 20th century, resulting in psilocybin syndromes without inducing fits of dancing.

For example, in 1932, S. Imai described cases of intoxications from 1929 and 1931 which involved his newly classified species *Stropharia caerulescens*. Later on, the species was named *Stropharia venenata* Imai, which grows on top of wood and dung. Today, it is being classified within the genus *Psilocybe* as a close relative of *Psilocybe cubensis*.

Imai mentions an event that occurred on June 21, 1929:

> *A 43-year-old woman collected about 13 oz. of a type of mushroom that she erroneously thought to be honey mushrooms (Armillaria mellea). The following day, she prepared a tasty mushroom meal and served it to her family. As family members began to notice the effects, they immediately*

> *went to see a doctor, who determined that the woman was experiencing the most potent effects: Her stomach was pumped without delay and laxatives were administered, but she still had muscle twitches, followed by hallucinations and a comatose (?) state. The son, who had eaten the soup only, experienced hallucinations as well, because the cooking process had served to extract the water-soluble compounds from the mushrooms.*

No Danger from *Psilocybes* in Japan

Unfortunately, Singer and Smith mistakenly cited these incidents in their (1958) monograph about the *Psilocybe* genus as examples of the mushrooms species' fatal effects. For that reason, this species was unjustly branded for decades in the literature as a highly dangerous poisonous mushroom.

There are other psychoactive mushroom species that grow in Japan, such as the bluing species *Psilocybe subcaerulipes* Hongo and *Psilocybe argentipes* Yokoyama. These species also caused intoxications in three people, who mistook the mushrooms for the honey mushroom. These cases brought about the isolation of psilocybin in crystalline form from dried fruiting bodies of the species, as well as recognition of the species' wide area of distribution. In 1973, Yokoyama published the results from systematic experimentation with *Psilocybe argentipes*. No "urge to dance" was noted in these investigations as well. Below are some excerpts from his research protocols:

> *J.H. (a 24-year-old male) ingested four cooked mushrooms at night, after a meal (!), and then ate another three fresh mushrooms 30 minutes later. This was followed by regurgitation, and 45 minutes later, he started to sweat profusely all over his head and body. His pulse rate and breathing were accelerated, but slowed down later on. He laid down and experienced visual hallucinations, which caused him to panic and to run a distance of about 1,200 ft. to consult the nearest doctor. The physician noted widely dilated pupils, and proceeded to have the patient's stomach pumped and then prescribed laxatives. Three hours later, the abnormal state had largely subsided; by the next morning, there was no evidence of any other side effects.*
>
> *M.K. (a 22-year-old male) ate just one fresh mushroom, which had no effects at all.*
>
> *K.Y. (a 31-year-old male) ate five mushrooms. Regurgitation occurred 30 minutes after ingestion, followed by sweating around the head and body; his extremities appeared to be slightly paralyzed. This paralysis persisted for another three hours. During this time, the subject had great difficulties handling a pen for writing, his mood was depressed and he experienced hallucinations, such as colorful lights flooding down from the sky. By the following morning, all of these effects had dissipated. The fresh fruiting bodies were bitter, a taste that disappeared after the mushrooms had been cooked in water.*

The above experiments are rather amateurish, and the descriptions of results are heavily influenced by a simplistic perspective which assumes that the mushrooms' pharmacological effects proceed along a single, narrow track. Still, these accounts demonstrate that comparable dosages of Japanese mushroom species have psychotropic effects similar to those caused by *Psilocybe* species found on other continents.

Much work still remains to be done in the areas of phytochemistry and taxonomy before the body of knowledge about psychotropic mushroom species in Japan can grow to become adequate. The geographic distribution and ingredients of the Japanese *Panaeolus* species must also be studied further. For instance, *Panaeolus subbalteatus* is one of the species that are growing on several Japanese islands today.

7.6 - Intoxications and the Oldest Known Mushroom Cult in Africa

So far, the mycoflora of the African continent has been studied only peripherally and remains largely unknown. During the late 1980s, Italian mycologist G. Samorini and Terence McKenna, working independently, found evidence for the oldest known mushroom cult in Africa. Their discoveries were not just sensational, but most surprising as well. On the other hand, it really shouldn't come as a surprise that the oldest traces of human contact with mushrooms were found on the very continent known as the cradle of humanity.

10,000 Years Old

From 9,000 to 7,000 years ago, the area of the Sahara - between Tassili (Southern Algeria), Acacus (Libya) and Ennedi (Chad) - was populated by human beings who created magnificent rock drawings, a pictorial legacy that preserved for posterity impressive images of everyday life. These pictures tell about a time when the Sahara was still a blooming garden, a time when no one even suspected that processes of erosion and desolation, starting about 3,500 B.C., would turn the area into a desert quite hostile to human life.

The rock drawings date from as far back as 10,000 B.C. up to the present. Among the drawings from the Stone Age (7,000-5,000 B.C.), there are those described as typical of the so-called "round head phase". They include pictures of pasture animals as well as evergreen and deciduous trees. On top of a Sahara plateau, at an altitude of 6,500 ft., there exist pictures of mythical beings with anthropomorphic and zoomorphic attributes which are reminiscent of early Mexican images: many scenes depict tiny horned dancers alongside mushrooms. Deities with masks and horns are seen holding mushrooms in their hands; sometimes the mushrooms are shown attached directly to body parts. In addition, those Stone Age artists created images of anthropomorphic beings with mushroom-like heads. There are many other indications pointing toward the existence of a comprehensive mushroom cult.

Among the most striking renditions at Tin-Tazarift, Tassili District (Algeria) is a picture of masked anthropomorphic beings engaged in ecstatic dancing. (See Figure 5, p. 8). This figure, "Anthropomorphic Beings Engaged in Mushroom Dance", includes several dashed lines, which are most interesting, because they connect the mushroom with the center of the head. At the same time, these lines represent a flow of energy, maybe even the mushrooms' influence on the human soul. This picture is clearly indicative of psychotropic mushroom use. It seems quite remarkable that, as early as 9,000 - 7,000 years ago, the head was apparently considered to be the seat of consciousness. By contrast, four or five millennia later, during the European era of classical antiquity, the brain's role was merely thought to be similar to that of a kind of cooler. Other rock drawings also depict mushrooms as being mythologically linked with fish.

These images, then, furnish powerful evidence for the usage of psychoactive mushrooms within a mystical-religious framework. The rock drawings consistently show two kinds of mushroom shapes: one of them resembles *Psilocybe semilanceata*, in that the caps are drawn with an acute umbo on top, while the other shape represents larger mushrooms with a habitus much like that of the *Amanita* or *Stropharia* species.

Despite their age, the rock drawings' colors have retained brilliant hues. Pictures of mushrooms were drawn in white as well as several shades of ochre. Also, a few mushrooms were drawn in blue colors. While this is the exception, it may well be a representation of the so-called bluing phenomenon.

In Nature, these colors are associated with the bluing *Psilocybe* and *Panaeolus* species. These mushrooms could have grown on several substrates, such as fallen twigs and raw compost, grounds littered with the remains from evergreen and deciduous trees or dung left behind by pasture animals. Among the mushroom species that may have grown in the area thousands of years ago, the most likely candidates are relatives of *Psilocybe cubensis* and *Panaeolus cyanescens* (dung-inhabiting species), *Psilocybe semilanceata* (a nitrophilic species) as well as *Psilocybe cyanescens*, a species that grows on top of raw compost.

Considering the impressive nature of existing historic evidence, the obvious question would seem to be whether any of these species can currently be found in Africa, where the cradle of mankind is located.

African Species Related to *Psilocybe cyanescens*?

Interestingly, on October 24, 1912, R. Maire first collected several specimens of bluing, dark-spored mushrooms which he found growing on raw compost underneath some cedar trees in Algeria, at Chrea Pass near the city of Blida south of Algiers. He collected additional specimens every year up until 1926 and published his findings in 1928, naming the species *Hypholoma cyanescens* nov. spec.

Later on, G. Malencon classified a number of similar specimens from his own samples collected in the Central Atlas Mountains (Morocco) as belonging to this species. In 1973, Singer then classified the species as

Psilocybe mairei Sing. Krieglsteiner, however, considered this species to be identical with *Psilocybe cyanescens* Wakefield, as found in Europe. Thus, bluing *Psilocybe* species can still be found in Africa today.

In his monograph on *Panaeolus* mushrooms from the 1960's, Ola'h mentions two *Panaeolus* species that are strongly psychoactive:

- *Panaeolus africanus* Ola'h and
- *Panaeolus tropicales* Ola'h.

There are also accounts from Africa about typical hallucinatory intoxications, caused by mistaken identification of a yellow *Stropharia* species as a culinary mushroom. In 1945, E.R. Cullinan and D. Henry described 22 cases in Nairobi, which occurred in July of that same year.

> *The symptoms started one hour after ingestion of the mushrooms, peaked within three hours and then persisted for 24 to 48 (?) hours. Symptoms consisted of emotional imbalance, fits of mirthful and irresponsible laughter alternating with depressive moods, during which patients felt they wanted to die. Patients were unable to sleep, due to nightmarish feelings that descended when they closed their eyes... They remained conscious throughout the experience and their speech, while somewhat uncontrolled, was rational.*

In 1957, A.D. Charters reported additional cases of intoxication from Nairobi:

> *On May 18, 1949, a man and his wife - both Europeans who resided in Nakuru, ate generous portions of mushrooms for lunch. Within 30 minutes, both of them developed mental symptoms, along with pupil dilation and a tingling sensation in the fingers.*
>
> *The man experienced visions of pink colors and a sense of euphoria in association with delusions. He felt that he was passing into the next life and he could see his own body. He stated that he realized "we are in the process of working toward our next life".*
>
> *His wife also reported delusions, and she felt that she was inside the tube that was part of the apparatus used for pumping her stomach at the time. She believed that she was going to die and she was afraid of death. She had laughing fits and felt sensations that alternated between happiness and depression. Both patients had their stomachs pumped and recovered completely within six hours.*

Given sufficiently wet climate conditions, *Psilocybe cubensis* can often be found in other parts of the world growing on pastures in areas located up to 30° north as well as south of the equator. Therefore, it is likely that the yellow *Stropharia* species from the Highlands of Kenya may actually have been *Psilocybe cubensis* mushrooms or at least a close relative of this species.

In January 1994, M. Smith and myself were collaborating in South Africa, where we discovered a bluing *Psilocybe* species in Natal Province. It was the first psychotropic *Psilocybe* species ever found in the area. This species is generally whitish in color and does not have an annular ring. The mushrooms are comparable in size to *Psilocybe cubensis*, but do not grow directly on top of dung in cow pastures. Having been compared with samples of known *Psilocybe* species, the new species is currently being published under the name *Psilocybe natalensis* Gartz, Reid, Ecker & Smith.

The mushroom samples and reports of intoxications described in this chapter indicate that psychoactive species do occur in Africa, which, in turn, supports the hypothesis of an ancient mushroom cult on the African continent. However, additional work is needed with respect to the African species, including their areas of distribution, their taxonomic classification and the essence of their active ingredients.

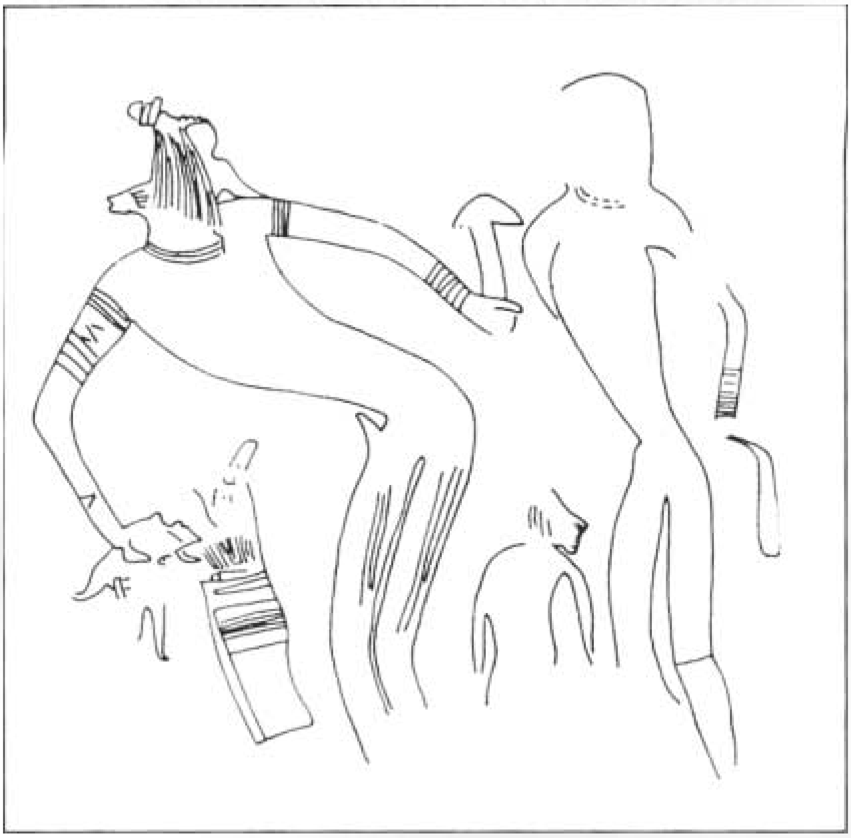

Figure 59 - Outline of a rock drawing from Tassili, Algeria (ca. 7,000 B.C.). The figure on the left clearly is holding a mushroom-shaped object.

7.7 - Usage in Southeast Asia and the South Pacific Islands

Since the late 1960s, the custom of using psilocybin-containing mushrooms has been evolving in various countries across Asia and the Pacific Islands. However, there is no conclusive evidence indicating that mushroom usage was endemic among native cultures prior to the discovery of the Mexican species. Most likely, global tourism has been the most significant factor behind increasing knowledge about relevant mushroom species among the populations of these countries, especially after searches for strongly bluing gilled mushrooms were successful. These mushrooms, most notably those found growing on pasture land, strongly resembled similar species from other continents.

Neo-Mycoflora

Western amateur mycologists helped disseminate information about these species and published articles on the mushrooms in various publications of their home countries. However, little or no efforts were made to identify and describe specific mushrooms species found growing in Asia and the South Pacific Islands. There have also been no research efforts to investigate the overall mycoflora in this part of the world. Thus, during the 1970s, a group of teenagers in Samoa discovered the psychoactive effects of *Panaeolus cyanescens*. At first, the police took measures to suppress the practice. But persecution by law enforcement agencies was halted when it became apparent that ingestion of the mushrooms did not pose a significant health risk. According to Cox, the teenagers' parents considered their children's mushroom experience "a foolish, but totally harmless episode and a part of normal teenage development". In light of such a reasonable frame of reference, the historic label "fool's mushrooms" (Chapter 2) immediately comes to mind.

By contrast, customs of psychoactive mushroom usage in New Zealand evolved around the same species found in Australia, with criminal penalties also modeled after Australian measures of law enforcement. However, in contrast to *Psilocybe semilanceata* and *Panaeolus cyanescens*, *Psilocybe cubensis* is not a species native to New Zealand, and all psychoactive species are generally referred to as "magic mushrooms".

To date, we do not know about all those geographic regions where the discovery of bluing mushroom species was an event that did not attract much attention, yet contributed to the mushrooms' growing popularity and an ever-increasing number of "silent" users. Scientific-mycological investigations of a small number of samples provided clues to the identification of psychoactive species relevant in this context: the two dung-inhabiting species *Psilocybe cubensis* and *Panaeolus cyanescens*, as well as *Panaeolus tropicalis*, a close relative of the latter species. In most cases, the differentiation of the two *Panaeolus* species is an extremely difficult task.

Panaeolus cyanescens Omelettes

During the seventies and eighties, the mushroom restaurants of Bali became quite famous, since interested tourists could order mushroom omelettes made with *Panaeolus cyanescens* - house specialties, and all completely legal to boot. At first, local children collected the mushrooms needed to prepare the dishes. In response to increasing demand for this culinary specialty, however, commercial cultivation of the *Panaeolus* species began, using the method of transferring dung with naturally-grown mycelia onto fresh buffalo manure.

Apparently, no major complications ensued, and this type of mushroom usage remained unchallenged for a long time. In Bali, ingestion of mushrooms has been limited, for the most part, to visiting tourists. In 1992, a German tourist reported that, if anything, the number of restaurants had increased compared to the 1980s. The number of restaurant patrons, however, appeared to have decreased, indicating an increasing familiarity with psychoactive mushrooms species in the tourists' countries of origin.

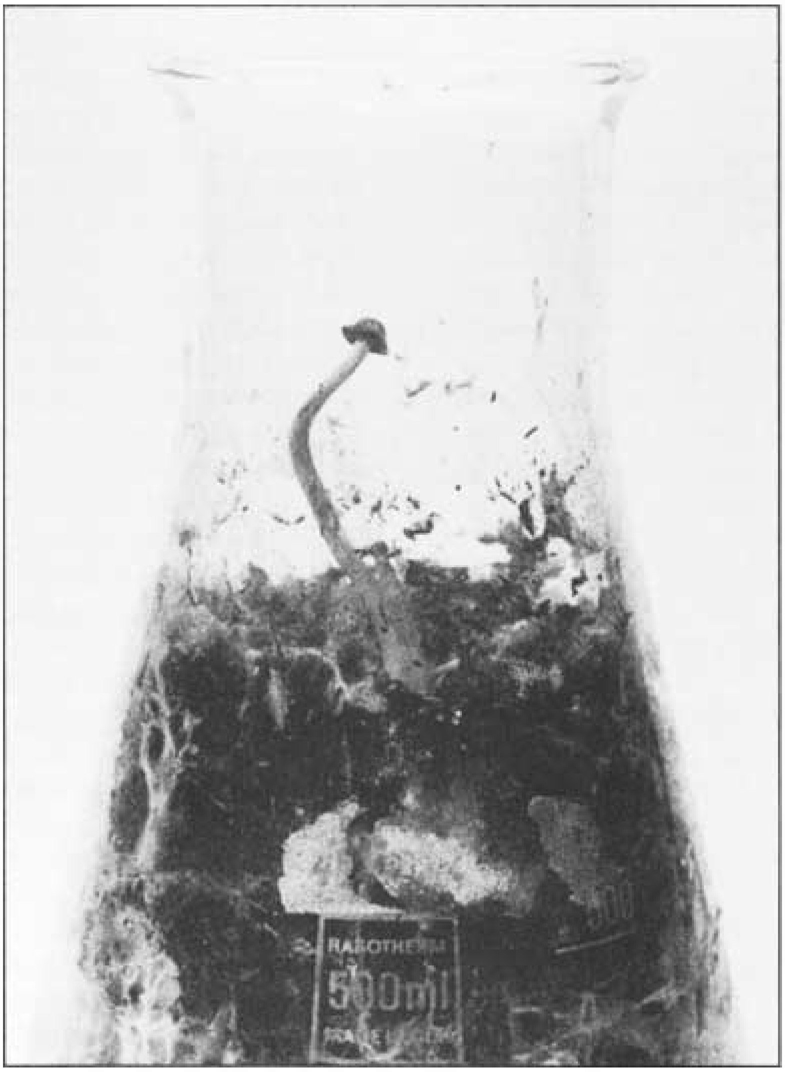

Figure 60 - ***Psilocybe samuiensis*** on a mixture of rye and horse dung.

Similar stories about mushroom specialties exclusively prepared for tourists have also been reported from Sumatra, Java and The Philippines.

Those mushroom species described above are based on samples collected from islands; thus, it is quite logical to expect finding those same species growing on the Asian mainland as well. Soon after Earle published his description of *Stropharia (Psilocybe) cubensis* in a 1906 edition of a Cuban agriculture journal, Patouillard proposed the species name *Naematoloma caerulescens* for his own samples of the same species, which were collected in Tonkin (Vietnam) in 1907. In Thailand and Cambodia, Heim found fruiting bodies of the species *Psilocybe cubensis*, providing the first sample from outside of Mexico used by Hofmann and his collaborators to confirm the presence of psilocybin in the fruiting bodies.

Such positive results inspired the proposal that psychoactive *Psilocybe* and related species thrive on all continents, a hypothesis that has been fully confirmed.

Other mushroom species from the genus *Panaeolus* have been found in mainland Asia as well. For example, Ola'h's monograph describes a bluing mushroom named *Panaeolus cambodginiensis* Ola'h & Heim, a species - as its name suggests - found only in Cambodia. According to Ola'h, all of the species's fruiting bodies contain psilocybin.

Monsoon Climate, Manure and Water Buffaloes

In 1981, Schroeder reported the results of his mycological field work conducted in Nepal during 1978 and 1979, where his research efforts established that mushrooms of the *Psilocybe* species are wide-spread throughout the area. Guzman proposed that these species can quite possibly be classified as *Psilocybe cubensis* and *Psilocybe subcubensis* Guzman. Macroscopically, the latter species is very similar to the subtropical *Psilocybe cubensis* species, but its spores are comparatively smaller and its habitat limited to tropical regions.

The mushrooms primarily grow in valley areas with monsoon climate conditions, at altitudes of about 3,000 ft. on substrates of partially decomposed cow manure as well as on water buffalo dung. While the species fruits all year round, it does so most abundantly in May and June, the rainy months that precede the monsoon season.

Nepal is another country where no evidence was found of any mushroom usage by the indigenous population. Mycophilic Western visitors, however, having discovered the species, soon indulged in usage of the mushrooms for hallucinatory purposes, a practice that failed to draw much public attention. It appears that a relatively large dose was required to achieve the desired effects, since several individuals consumed forty or more of the fleshy mushrooms at a time.

"Soma": A Psilocybian Species?

Within the context of discovering this species, Schroeder and Guzman proposed a most interesting hypothesis. They suggested that "soma", the substance revered as a deity by the mysterious, ancient Aryan civilization, who are said to have developed a soma cult, did not, in fact, refer to the fly agaric mushroom, as initially proposed by Wasson. More likely, soma was the name of a psychedelic *Psilocybe* species, based on its spectacular psychotropic effects and the mushroom's geographic distribution pattern.

An article authored by J.W. Allen and M.D. Merlin concludes that currently Thailand is the country with the largest consumption of psychoactive mushrooms.

In several areas across Thailand, tourists can find menus offering mushrooms prepared as part of omelettes, soups, teas, pizzas or juices. Allen specifically studied patterns of usage on the two islands of Koh Samui and Koh Phangan. Previously, sporadic reports from other islands off the Thai coast contained descriptions of similar practices there. In January 1990, Allen also confirmed usage of the mushrooms in the northern areas of Thailand.

German Tourist Boom

On Koh Samui and Koh Pha-ngan, the mushroom dishes are enjoyed primarily by German tourists. Along with a few other foreigners, some Thai teenagers use the mushrooms as well, sometimes even attempting to smoke them in a bamboo pipe. As a salt-like chemical compound, psilocybin requires temperatures of about 200°C for it to melt and partially break down without sublimation, so that a tobacco pipe will not be effective in achieving the desired psychoactive effects.

During the fall of 1988, Thai authorities distributed warning leaflets at tourist centers, providing a detailed description of a bizarre panic reaction experienced by an Australian tourist, who was hospitalized briefly as a result. Allen thoroughly analyzed this event by seeking additional information about the circumstances of this case, including interviews with all other individuals involved. Allen discovered that the Australian visitor had used excessive amounts of various pharmaceuticals, including highly addictive substances, which is why he eventually required hospitalization.

Finally, in January 1989, this incident was central to justifying passage of a law that prohibits usage of psychoactive mushrooms ("hed keequai" in local language), with harsh penalties provided for non-compliance. Until that time, many restaurants posted signs advertising the various types of mushroom dishes on their menus. But mushroom usage continued despite passage of the law. Specific species still being used were identified as *Psilocybe cubensis*, *Psilocybe subcubensis* and *Panaeolus cyanescens*. It is unknown if a tourist in Thailand has ever been sentenced for usage or possession of mushrooms. In addition to the collection of fruiting bodies growing naturally on buffalo dung, Thai as well as German residents on Koh Samui and Koh Pha-ngan began to cultivate the mushrooms, outdoors and inside houses. In accordance with the "natural cultivation" approach, rice debris was added to fresh manure and mixed with dung already permeated by mycelia. After prohibition, mushroom cultivation continued at hard-to-reach wilderness locations.

Moreover, Allen found evidence that some restaurants temporarily served dishes made from regular table mushrooms apparently spiked with a synthetic hallucinogen (LSD?) whose effects lasted much longer than those of psilocybin. This dangerous practice caused unexpected reactions with effects lasting for up to 10 hours. Some consumers experienced dysphoric side effects which persisted for as long as several days. One individual developed an aversion against all kinds of mushroom dishes for several months.

As in Mexico during the sixties, a large variety of mushroom images and products are marketed commercially in Thailand these days. Among merchandise offered for sale there are hand-painted and mass-produced T-Shirts (see Figure 56, p. 78) with pictures of *Panaeolus cyanescens* and *Psilocybe subcubensis*, shown together as well as separately, not to mention postcards, posters, lighters and key rings, all featuring mushroom-motif decorations. Allen reported that such goods are available in both Northern and Southern Thailand.

In coming years, we can well expect a wealth of new discoveries and insights into the ethnopharmacology, taxonomy and natural chemistry of Asia's mycoflora.

Not surprisingly, another new mushroom species was discovered in Thailand in August, 1991 and named *Psilocybe samuiensis* Guzman, Bandala & Allen (see Figure 60, p. 99). The species is similar in appearance to *Psilocybe semilanceata*, but the fruiting bodies do not contain baeocystin. *Psilocybe samuiensis* is a bluing species that grows on fertilized soil, but not directly on top of dung. We successfully cultivated this species on a mixture of rye, horse dung and water (2:1:2), but found that we needed to add a casing layer consisting of peat and chalk (2:1).

CHAPTER 8

Some Comments on Effects of Mushrooms from the Category Phantastika

Extensive animal research efforts during the 1950s furnished evidence that both psilocybin and psilocin are alkaloids of negligible acute toxicity. Specifically, the dosage of psilocybin that caused death in 50% of the experimental mice (LD 50) was determined to be 280 mg/kg body weight. By comparison, noticeable effects in humans generally occur at dosages as low as 0.02 mg/kg.

Animal tests showed that, on average, psilocybin was a substance only half as toxic as mescaline, and at the same time, turned out to be 50 times more potent as a psychoactive substance. For example, up to 2 g of mescaline were being administered with no dangerous side effects, while the usual dose of psilocybin ranged from 3 to 30 mg as part of psychological testing and psychotherapy sessions.

As is the case with other psychotropic substances, human beings most likely have a more sensitive reaction in response to psilocybin than mice do. Still, the range of safety in controlled experiments comes to several hundred times the amount of the active dosage. The same goes for the consumption of mushroom material, since psilocybin concentrations in mushrooms can vary up to a factor of 10. Consequently, J. Ott speculated that adults would need to eat their own body weight in fresh mushrooms, in order to finally reach the dosage limit of lethal toxicity. Despite the hundreds of thousands of voluntary self-experiments taking place every year in the U.S. alone, no fatalities caused by magic mushrooms have ever occurred there. Small children, however, have abnormal reactions to psilocybin, such as loss of consciousness, cramps and danger of death.

> *It was in the fall of 1960, that a child from Milwaukee, Oregon, picked several mushrooms from grassy soil below a cluster of conifers. Having eaten the mushrooms, the child experienced cramps and a high fever. Similar to a condition described as "status epilepticus", the symptoms were treated by medications, with limited success. The child died within three days.*

The mushroom sample involved in this incident was identified as *Psilocybe baeocystis*. P. Stamets, however, contested this finding, claiming the species had been misidentified. He referred to a publication about the incident that included a picture of the mushrooms, which, according to Stamets, shows a sample of *Psilocybe cyanescens*. This species is well-known as exceptionally potent, due to high levels of psilocybin and psilocin. Still, we cannot determine whether toxic concentrations of alkaloids were the cause of death, or whether ingestion of the alkaloids triggered a latent case of epilepsy in the form of an acute episode that could not be treated or controlled. If a similar incident happened nowadays, fatal outcomes could be easily prevented, since the last three decades of progress in pharmaceutical research included the discovery of new drugs capable of aborting convulsive episodes.

Due to publicity generated by the unfortunate accident in 1960, two alkaloids (baeocystin and norbaeocystin) first isolated from *Psilocybe baeocystis*, at times acquired reputations of being extremely poisonous as well as strongly psychoactive. Both claims, however, are wrong and unsubstantiated. Specifically, both baeocystin and norbaeocystin are present in other mushroom species, such as *Psilocybe semilanceata*, and at generally higher levels compared to the alkaloid content of *Psilocybe baeocystis*.

Biochemical research efforts accelerated and large numbers of studies were conducted, primarily with LSD. These investigators sought to discover the receptor binding sites for hallucinogenic compounds in the brain and to understand the mechanisms underlying the genesis of psychedelic visions. Today, we still lack a sound theoretical framework able to explain the relationship between chemical compounds and the manifestation of their psychoactivity. Even though basic research is certainly important, its methods, unfortunately, are often a function of a rather one-sided pharmacological approach to investigating the effects of psilocybin, LSD and mescaline - an approach that is, in fact, too narrow to address the remarkably unusual nature of these substances and their effects.

Misunderstandings between pharmacologists and toxicologists on the one hand and psychiatrists and psychologists on the other can often be traced all the way back to the 1950's, creating a legacy of disputes and arguments that have yet to be resolved. S. Grof undertook the tedious task of analyzing 5,000 experimental LSD protocols in an effort to isolate "absolute" symptoms that are reported or occur all of the time. His results were negative. According to Grof, hallucinogenic substances are non-specific triggers causing a sequence of altered states of consciousness, which do not fit the syndrome labeled "toxic psychosis". Rather, it is the individual's personality, along with the experimental setting that significantly shape the nature of the psychedelic experience. This view is shared by a majority of experts with considerable experience in conducting psychedelics-assisted psychotherapy. Even "real" somatic symptoms, such as nausea or vomiting, can often be controlled through psychological intervention techniques administered by trained professionals.

A Plethora of Names

The broad range of possible experiences inspired the use of labels other than "hallucinogens", with widely differing semantic connotations: entheogens, psychedelics, illusionogens, psycholytics, psychomimetics, psychodysleptica, psychoemetics and others.

"Phantastica" (Lewin) is the oldest label ever used to describe this class of substances. This term successfully evokes dream-like, fanciful aspects of the experience, as well as the potential for euphoric and dysphoric emotional overtones. More recent terminology often says more about semantic biases of those who use the labels than about any factual, objective characteristics of the alkaloids they refer to. Accordingly, official antidrug propaganda since the 1960's has disparaged "psychedelics" as excessively glamorous and too positive a label, as the term was popular among Timothy Leary's fans and supporters.

When used in low doses or for the first time, these substances are most likely to bring about a kind of magical transformation of surroundings, with a heightened ability to perceive subtle differences along the color spectrum - effects an individual often takes in with a great sense of wonder and awe. Based on these types of experiences, the label "psychoesthetica" has been used as well.

During the 1950's, those experiments of a purely pharmacological nature revealed that, within a specific low dosage range, the effects of psilocybin and LSD were largely similar, except for the shorter duration of the psilocybin experience. That is why there are numerous comparisons in the literature of 10 mg of psilocybin with 100 µg of LSD as equivalent dosages.

There are several authors, however, who focus on the more visionary and metaphysical nature of the psilocybin experience compared to other hallucinogenic substances. A. Hofmann conducted self-experiments with both substances and found the altered state of consciousness induced by psilocybin to be both deeper and somewhat gloomier than those produced by LSD.

Other investigators have portrayed psilocybin as "friendlier" - a substance that is not as fierce as LSD in exposing possible traumas hidden within the subconscious mind (see Chapter 3.2). Such differences in comparative evaluations of psilocybin and LSD are likely linked to a variety of factors, such as dosage differences, research protocols less than comprehensive and exhaustive in scope, as well as personality and environmental variables.

LSD "Flashbacks"

R. Fischer conducted a series of experiments designed to study the effects of psilocybin compared to LSD and mescaline. The results confirmed what had already been common knowledge among those who used the mushrooms in various contexts around the world: "flashbacks" are quite rare, and very mild, if they occur at all, nor do abnormal symptoms persist once the effects of the alkaloid have worn off. Widespread reports of LSD-induced "flashbacks" spawned biochemical theories which falsely postulate that LSD is stored inside the body and can be released at a later time to induce short periods of visions and other "psychotic" manifestations. Such conjecture about the body's "storage capacity" persisted despite prior evidence to the contrary that established LSD as a substance rapidly metabolized and eliminated from the body.

The assumption of a prolonged storage period following ingestion of LSD had already been debunked by LSD-assisted psychotherapy during the 1960's. According to M. Hausner, who worked in the former

Czechoslovakia, several patients who went through a series of LSD sessions did experience "flashbacks" in between sessions. However, the therapeutic administration of hallucinogens was continued in these cases and those flashback episodes that did occur were far less spectacular than expected based on some of the more dramatic descriptions of the phenomenon. Within the context of M. Hausner's studies, flashback episodes turned out to be merely temporary manifestations of issues that had reached the conscious mind. Moreover, flashbacks disappeared as therapy progressed with continued administrations and did not recur after conclusion of the therapy program. These observations are at odds with the biochemical theory which predicted that repeated administrations would increase storage of the substance inside the body, causing increasingly powerful flashback episodes.

Considering the highly variable nature of psilocybin's effects as illustrated by examples of unintentional and carefully controlled experimentation described in this book alone, some striking parallels with Grof's findings on the effects of LSD virtually suggest themselves. Grof noted the emergence of, in that order, abstract, aesthetic, psychodynamic, perinatal and transpersonal types of experiences during hallucinogenic sessions. With repeated administrations of relatively low doses, participants typically progressed through these stages one by one, eventually attaining and lingering at the transpersonal level of analysis.

The accounts of psychoactive mushroom experiences included in this book are by necessity limited to only one to three trials over time. Thus, detailed analyses comparing the effects of LSD and psilocybin must await results from future research efforts, assuming researchers will be able to conduct these types of studies.

By contrast, relatively high doses of LSD as well as psilocybin typically "bypass" the initial phases of experience, propelling the individual directly into the realm of transpersonal consciousness. The natural scientist's first experiment with *Psilocybe bohemica* or the incidents of accidental intoxication with *Psilocybe cubensis* in Africa both illustrate these kinds of transpersonal experiences.

Aside from psilocybin's psychotherapeutic applications as detailed in Chapter 9, there are other interesting phenomena and potential uses for psilocybin as well as those mushrooms whose active ingredients can be analyzed and measured accurately.

The investigation of frequent symptoms such as compulsive laughter, yawning and the flow of tears without dysphoria may reveal interesting neurophysiological mechanisms, provided we can isolate and separate the influence of psychological factors in the manifestation of these symptoms.

Psilocybin as a Research Tool for Study and Diagnosis of Brain Damage

The benefits of diagnosing brain-damaged patients with psilocybin were investigated in the former Czechoslovakia during the 1960s. Psilocybin was the alkaloid of choice for these studies, due to its minimal toxicity and because participants were not expected to develop additional chronic dysfunctions as a result of ingesting psilocybin. Visual hallucinations were found to be almost completely suppressed in patients suffering from lesions to parts of the central nervous system known to mediate visual-sensory functions.

On the other hand, the discovery that psilocybin tended to potentiate a variety of neurological processes effectively turned the alkaloid into a diagnostic tool used to reveal latent paralyses and other subtle types of damage to the central nervous system. While LSD could also have been used for this purpose, researchers preferred psilocybin, because dosage measurement was comparatively simpler, its effects were short-term and patients experienced less fatigue with psilocybin than with LSD.

In one exceptionally remarkable case, *one of the participants, while under the influence of the substance, clearly saw a brain tumor inside her skull - a tumor that was not discovered until an examination that followed the session.*

R. Fischer (see Figure 61) conducted a series of controlled experiments *involving the presentation of words and sentences composed of incomplete letters, with increasingly larger portions of the letters covered in several stages, from the top down. In the end, only the stumps of the letters remained in the display, which* *was no longer readable. Under the influence of psilocybin, however, the ability to "re-synthesize" these characters was observed quite frequently: Participants were able to read a significantly larger number of words, with some reportedly able to see the partial letters, complete and uncut, in a display that showed little more than a white background area.*

These observations are powerful evidence confirming that the effects of mushroom ingredients are certainly not just "psychotic" in nature, a notion preferred by those pharmacologists partial to terminology such as "toxic psychosis", with all its connotations as evoked by the "fool's mushroom" label. Psilocybin and its relatives apparently act as catalysts that initiate new information processing mechanisms and patterns of coordination between the different interactive areas of the brain. As such, the substances create the context needed for integrating emotional and rational processes in new ways. Under the most favorable of circumstances, such states of mind are experienced not only as a profound, impressive expansion of one's consciousness, but may also be reflected in short-term improvements of performance. I believe, however, that these temporary gains in skills are rarely attained by casual or recreational users of psilocybin-containing mushrooms, because set and setting are often less than ideal, and alkaloid content tends to be highly variable. Most researchers, including A. Hofmann, strongly advised against usage of hallucinogens by youngsters, even in controlled experimental settings. Adolescence is a time of upheaval, a developmental stage when youngsters struggle with themselves and their surroundings, searching for a purpose and a firm direction in life: Numerous conflicts arise in the process and need to be dealt with and integrated. Besides inducing altered perceptual states, hallucinogenic substances, including psilocybin are bound to release a stream of new emotions and conflicts. Such experiences often serve to confuse teenaged users and to compound existing areas of conflict, threatening to disturb the youngster's equilibrium, which is rather fragile to begin with.

Quite likely, the search for a means to escape reality plays an important role in this situation. In fact, the escapist aspect of LSD portrayed against a backdrop of political upheaval fuelled a reactionary zeal among those determined to control the substance during the 1960's. As a consequence of these restrictive legislative measures, the unbiased, scientific evaluation of hallucinogenic substances remains an all but impossible task. These examples from the LSD research literature suggest that controlled human subjects research is possible without risking damage or injury to the participants, while gaining a wealth of new insights beyond psychotherapy applications.

Comprehensive investigations of these substances have long ago proven beyond doubt that psilocybin, mescaline and LSD are not physically addictive, nor do they cause withdrawal symptoms of any kind. Repeated self-experimentation over long periods of time is rare; most long-term users eventually reduce frequency of use due to the nature of these substances that initiate powerful transpersonal processes and facilitate the emergence of personal conflicts. Besides, habitual daily users quickly develop tolerance to the point of being unable to experience any psychoactive effects at all. That is why clinical trials are spaced to allow for intervals of at least one week between repeated applications.

Ecstasy is More than Entertainment

Renowned pharmacologist R. Siegel described hallucinogenic mushroom consumption in California as merely "experimental use". According to his definition, almost all users of psychoactive mushrooms have anywhere from at least one up to 10 experiences, with several weeks or months in between repetitions. Or consider R. G. Wasson's poetic answer to a question from his banker friends who wanted to know why he did not eat the mushrooms every day:

> *"There are many who never experienced ecstasy and who may think this is entertaining. But ecstasy is not a form of entertainment: trembles. What kind of person would think nothing of submitting to a sense of pure, absolute awe or of floating through that doorway into the presence of the divine? Those who have never known ecstasy first-hand, distort the word each time they use it. We must comprehend anew the entire, frightening meaning inherent in this word.*

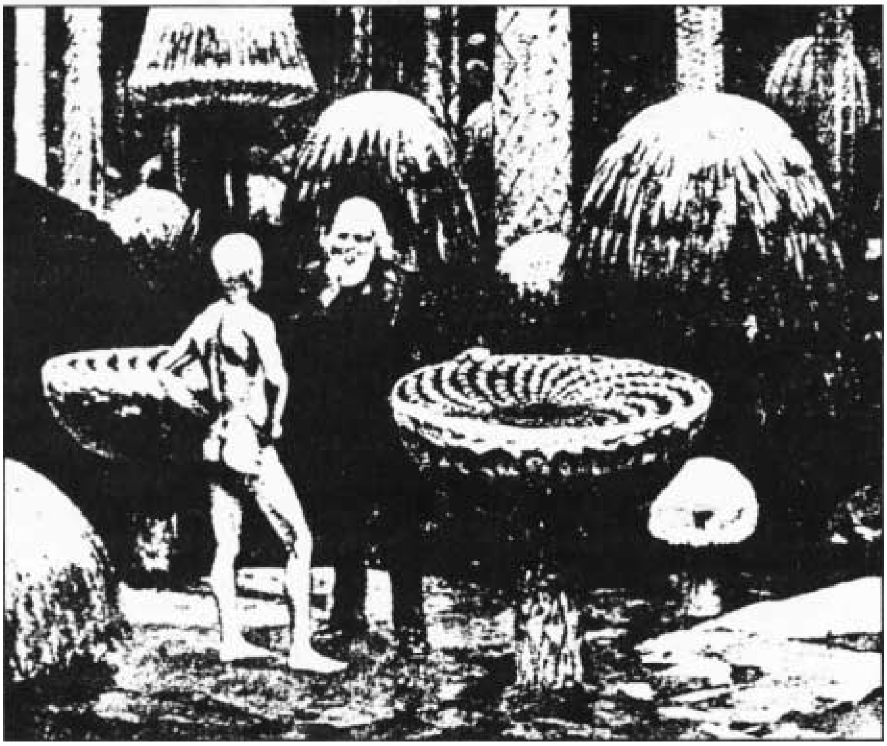

Figure 63 - "*Handing me one of the halves, he spoke the single word, drink.* " From *Etidorhpa* by J.U. Lloyd (1904).

CHAPTER 9

Psychotherapy

We live in an era of profound sociocultural changes, while a growing sense of insecurity pervades many areas of our lives. At the same time, our achievement-oriented society has fostered a set of values propagated by industrious, hard-working and successful citizens. Naturally, not all members of society are able to embody these ideals or embrace them all the time.

Psycholytic Therapy

Oftentimes, the origins of chronic neuroses are rooted in early childhood. Neurotic behavior can evolve under a wide variety of circumstances that include combinations of unfortunate personal and social conditions. There are numerous forms of neuroses and symptoms can vary considerably. Neurotic disorders afflict a large segment of the population, significantly impairing their quality of life.

According to the various schools of traditional psychoanalytic thought, the dissolution of neuroses is a lengthy process, whose progress depends on penetrating layers of "character armoring" and identifying the root causes of unhealthy fixations. Hoping to shorten the duration of treatment by accelerating the pace of resistance dissolution practitioners, have turned to pharmaceuticals as an adjunct to the therapeutic process. Thus, upon discovery of the unique properties of hallucinogenic agents during the 1950's, LSD gained widespread popularity as a therapeutic agent, while mescaline remained obscure, as it was used by comparatively few practitioners. Patients under the influence of these substances confronted long repressed traumatic events as they began to surface and enter conscious awareness. In some cases, such emerging traumatic experiences had been repressed since early childhood. Medical records and case histories indicate that many patients not only remembered, but actually relived traumatic experiences in their past.

At this point, I would like to summarize the major elements of this psychotherapeutic approach, based on the excellent books written by H. Leuner, S. Grof and S. Widmer. From a variety of different perspectives, these authors thoroughly examine the therapeutic process, drawing on extensive clinical expertise representing decades of experience in several countries.

At times, critics from within the psychiatric establishment have claimed that a "short-term high" is simply not capable of propelling complex processes into conscious awareness, and that psychoactive substances are no short-cut to quicker treatment. These are weak objections at best, because we already know that the awesome intensity of an unfolding psychedelic episode is sufficiently powerful to propel individuals towards gaining valuable insights of a highly personal nature (see accounts in Chapter 3.2). Such landmark experiences are likely to stand out as significant personal milestones whose impact will not diminish for many years, even if the individual never uses the substance again. On the other hand, due to the profound, far-reaching nature of the psycholytic process, skillful and responsible guidance is crucial to preventing the genesis of new sets of neurotic symptoms. Whenever a new therapy is adopted, occasional mistakes are not uncommon during the initial phases. The medical use of hallucinogenic substances was no exception. However, our knowledge base and expertise on essential practical procedures has grown considerably since the pioneering days of psycholytic therapy. Having learned from initial errors, we can now prevent problems and avoid mistakes.

Psilocybin as the Drug of Choice

Following its initial isolation and discovery of its chemical structure, psilocybin quickly joined the group of hallucinogens used in therapeutic settings. The alkaloid was considered to be quite safe, based on existing toxicological data. H. Leuner still considers psilocybin the most effective alkaloid for use as a pharmaceutical aid in psychotherapy, despite recent progress in developing other substances designed for therapeutic applications, such as the substituted phenethylamines like MDMA. Psilocybin's reputation as a substance well suited for psychotherapeutic applications is related to its extremely low toxicity. Most importantly, dosages below the 10 mg threshold can be measured with accuracy. This is significant, because dosages of up to 10 mg are not only known to be therapeutically efficient, but effects within this dosage range can always be brought under control. The states of consciousness induced by psilocybin last only five hours, on average, and thus can be more conveniently utilized than altered states caused by LSD, whose effects persist for much longer time periods. LSD should be considered a more difficult substance to work with, due to the possible emergence of unwanted symptoms in a small percentage of users and the prolonged process of "coming down" when symptoms subside. Unlike other hallucinogens, psilocybin also has the advantage of almost never inducing "hangovers" the day after experimental sessions.

It is important to note in this context that all authors stress that hallucinogens are no substitute for lack of skills on the part of the therapist and that the usage of these substances should remain limited to carefully selected cases. Usage of hallucinogens "merely" shortens the duration of psychoanalytic treatment, as problem conflict areas surface faster and with greater clarity, mediated by the process of self-exploration and discovery that is the essence of psychedelic experiences. Repressed patterns of normal behavior and reactions must be gradually reconstructed within the therapist-patient relationship.

The capacity for emotional immersion into one's own problems under the influence of a psychoactive substance is provoked and amplified by the emergence of memories, as well as the elimination of the Me/You boundary. As this process unfolds, the therapist gains valuable insights into existing psychopathologies and psychodynamics. Still, in addition to providing proper guidance for the patient, the therapist must also be able to separate bizarre forms of alienation that may appear from the emerging conflict matter.

The Language of Statistics

According to statistical data, psycholytic therapy is a remarkably efficient form of treatment, most notably in patients suffering from neuroses. A follow-up study of 82 patients showed that 65% of them showed long-term, clinically significant improvement. In all, 28 authors described 1,600 therapy cases, covering 42 investigations that took place from 1953 to 1965. The course of illness was judged very grave and chronic in 68% of the cases. The administration of hallucinogenic substances within the psychotherapy setting resulted in success rates of up to 70% ("good and substantial improvement"), especially in the treatment of neurotic anxieties, depressive-neurotic dysphorias as well as neurotic character disorders.

In the former Czechoslovakia, M. Hausner also tested *Psilocybe bohemica* for psycholytic therapy sessions, with successful outcomes comparable to those observed following administration of LSD. For many years up until 1974, Hausner has used LSD with more than 350 patients in about 3,000 sessions. In Mexico from 1967 until 1974, S. Roquet developed an interesting modification of the therapeutic technique ("psychosynthesis") where hallucinogens are used as an adjunct to the therapy process. His conceptual approach was strongly influenced by the shamanistic uses of different substances in his home country. Groups of 10 to 20 people experienced effects of a diversity of substances (psilocybin mushrooms, peyote, LSD, ololiuqui). While stereo music played in the background, several slide and film projectors were used to present images whose emotional content ranged from pictures of love to scenes of horror. Thus, in addition to hallucinogen-induced emotional stimulation, patients are also exposed to powerful external stress factors, modifying the experience into one of a very deeply emotional nature. Duration of treatments varied from 18 months up to two years, with many hours of drug-free therapy and, on average, one hallucinogen-assisted session a month. On a few occasions, patients received the substance in individual settings. Roquet reported successful treatment of neurotic character disorders in 85 of the patients. The psychoanalytic and transpersonal elements of a substances' effects were considered therapeutic agents, supported by sustained positive feelings among group session participants.

The Conquest of Fear in the Face of Death

During the 1960's and 1970's, most therapists in Europe were limiting the scope of their work by exploring only the psychodynamic level of behavior. Elsewhere, however, practitioners of hallucinogen-assisted therapy dispensed large doses of psychoactive drugs, maximizing the emergence of transpersonal states of consciousness that often resembled mystical experiences. These episodes of transpersonal transcendence ("psychedelic therapy" in the U.S.) contribute to the therapeutic process; they may even be the sole source for future progress.

Under these conditions, stereo music also significantly deepened the intensity of the experience. It appears that these kinds of specific experiences may also account for the remarkable success of treating terminal patients with LSD to ease their fears in the face of death and to reduce even the most severe forms of pain. In many such cases, symptoms disappeared entirely, and relief from pain and anxiety that continued even after the drug's acute effects had worn off. A book by S. Grof provides a compassionate analysis of such successful treatments, which serves to underscore the fact that systematic efforts to investigate these particular therapeutic benefits have only just begun. So far, LSD has been the most widely studied substance in terms of easing the suffering of terminally ill patients, as well as dipropyltryptamine (DPT), a synthetic drug structurally similar to psilocybin that is active only when administered by injection.

Below, a young woman from Switzerland gives a detailed account of her second mushroom experience. Her first experiment, with *Psilocybe cubensis*, had already introduced her to the realm of mystical experiences. For her second journey, she used 20 *Psilocybe semilanceata* mushrooms as part of a group ritual and achieved transcendence. A remarkable feature of her account is that the presence of an experienced guide was needed to realize the full potential of this visionary quest.

> *"I sat down next to another participant, seeking to connect with others in preparation for my journey. We proceeded to eat the fresh mushrooms. The room grew quiet and lovely music began to play. The mushrooms' effects came on much faster than they did during my first experiment. Twice I tried to establish closer contact with my fellow participant, but he was very nervous, and no source of reassurance for me. I was seeking my spiritual companion, but did not find that person among the present group. I became a figure in a long, white robe, wandering aimlessly among the columns (Greece?), still searching.*
>
> *My gaze lingered briefly on the wall next to the door and I saw faces and figures appear and vanish, but they did not hold my interest. It was hopeless. I continued my aimless roaming, and I was on the material plane, which I wanted to leave - had to leave. Suddenly, I found myself with one of the guides, who wanted to help me. I stared off into the distance, longing to be free of the material plane, but unable to do so. For a long time, I failed to connect with the guide; our two worlds were just too different. Suddenly I sensed that he wasn't able to look at me directly. The path by which to reach me runs through my eyes, because only they are truly alive. I asked him to help me on my way and invited him to look into my eyes. I felt as if all life energy was draining from my body and my breathing became erratic. My body contracted, struggling to cast off its worldly shell. The guide began to talk to me in a calm and quiet voice, then laid back down and stroked my right arm. Quite suddenly, I felt at peace. I took a deep breath and relaxed. The guide said that it's alright, to just let go, to give up my resistance. The goddess awoke and told him that he is the one resisting. Why? Didn't he want to learn anything about me? I smiled the goddess's smile and had become her, as he replied that he was afraid of my eyes, because they appeared so bottomless and dark that he feared losing himself in them. I answered that I was dangerous, the Goddess Kali the Terrible, a man-eater, and that he should look at me and enter. My gaze penetrated him into eternity; a connection had finally been established. His face turned green, covered with moss and I saw horns. It was a kind face, yet full of cunning, a little devil's face, like Pan's. At times, stripes streaked across his face; I had become a seer.*
>
> *I saw a child, a young man with blond hair cropped just above his shoulders, ca. 17th century. He is busy writing, inside a small house located in a city; a poet perhaps, or a scribe? Germany or Holland? This was a state of infinite harmony, a light that seemed to come from everywhere and nowhere at all; something that had always been there and always will be, something that simply exists. There is no past and no future. Consciousness beyond body and barriers, infinite, all-consuming; an infinite, universal love that embraces everything. I had a strong sense of agelessness, because I embodied a principle that had always existed. How intensely I felt these unearthly emanations, this very eternity. I saw through what appeared to be a succession of many caves, through myriad dimensions, and all of them were flooded with light - my energy. An energy existing simultaneously at its source as well as throughout eternity. This was a plane of utter harmony, devoid of contrasts such as good and evil, marked by the overwhelming peace of a spirituality both cosmic and infinite. The Goddess smiled. I no longer existed as a woman and as such could not be reached by others.*

> *After that, the effects began to subside slowly. In the presence of my guide I felt infinite protection and total understanding. Under his guidance and protection, I began to ease into the slow and gentle descent back to my earthly state of being. In the process, I found myself able to switch back and forth repeatedly between both states of consciousness. I realized that even my deepest agonies had become insignificant over "on the other side ". Furthermore, I understood that all the religions with their sets of rules had been created at one time or another for the sole purpose of providing guidelines for humanity, yet excessively narrow interpretations of these rules have rendered them all but irrelevant. Anyone who embarks on a deliberate search for a higher harmony, seeking spirituality, has no need for such rules at all."*

It is instructive to consider some of the comments made by R.G. Wasson's wife Valentina Pavlovna, as they appear in the second report about Mexico's magic mushrooms in 1957, written in the wake of experiencing the impressive effects of her self-experiment. A medical doctor by profession, V. Pavlovna brought up the potential for medical applications, given successful isolation of the active mushroom ingredient. According to her writings from that period, she believed the substance to become a significant new tool in the study of psychic processes, that it would benefit the treatment of alcoholism, drug addiction and mental problems, and help ease the suffering of terminally ill patients with severe pain. It was several years later that a number of researchers, unaware of V. Pavlovna's article, began to treat these very same conditions with LSD, a substance that is much harder on the patients' systems than psilocybin!

The medical use of psilocybin, a basically non-toxic substance, as well as mushrooms with known active ingredients, should, in my opinion, be permitted with terminally ill patients. The promise of easing the suffering of dying patients alone should be reason enough to allow the use of psilocybin and related substances, considering the reality of fatal illness as one of the grimmer universals of human existence. Many psychiatrists and pharmacologists maintain that the mystical aspects of hallucinogenic substances should be described more accurately as psychotic in nature, and that repeated manifestations of these symptoms are cause for worry and concern, since their existence and nature cannot be explained. The convictions behind these beliefs, however, pale compared to the promise of being able to provide that which strikes at the very essence of practicing medicine: to help patients endure the ultimate anguish of impending death, while making sure they are not left alone to deal with pain and fear.

Scientific Research Under Fire

It was about 30 years ago that legislation was enacted severely restricting the use and availability of hallucinogens. It is most unfortunate that these sweeping prohibitions dealt a crippling blow to legitimate research efforts, forcing more and more investigators to abandon this area of study. Thus, despite the success of psycholytic therapy, its practice was discontinued during the 1970's. In retrospect, a calm and pragmatic analysis of these events can surely help us recognize that those years of pioneering research laid the foundation for the development of a whole new form of treatment - one that has already proven effective in aiding the healing process and relieving the symptoms of hundreds of gravely ill patients in various countries around the world. In many cases, improvement occurred after all previous methods of treatment had failed completely. Today, we are faced with a situation so bizarre it defies reason and logic: the entire pharmacological class of hallucinogens is subject to even more severe taboos than truly addictive substances that do have legitimate medical uses, such as the morphine-type drugs and their derivatives.

H-Bomb for the Soul?

The irrational fears surrounding the "proper functioning" of our consciousness were responsible for the genesis of two very extreme views about LSD during the 1960's, dating back to the earliest phases of research into this substance. Proponents praised LSD as a "miracle drug", while its detractors were quick to brand LSD the "devil's drug" (or "an H-bomb for the soul"). It was the latter group that prevailed in the end by way of political power.

This controversy, already a matter of historic record, has been marked by a pattern of confusing emotion with scientific standards. Today, we are surely capable of overcoming past controversies, by embracing a rational approach to resolving problems and issues of contention. Viewed objectively, an unbiased assessment of hallucinogen-assisted psychotherapy is possible only in terms of measuring success. In order to do this, however, we must be allowed to use these substances in therapeutic and unbiased scientific settings.

There is some hope that current lop-sided attitudes against hallucinogens may be changing for the better, as efforts by the Swiss Medical Society for Psycholytic Therapy to re-legitimize hallucinogen-assisted therapy have met with modest success. In 1988, the Swiss gave permission to a few selected psychotherapists to use psychoactive substances for psychotherapeutic purposes, at least within a narrow range of strictly defined conditions and for a limited time. Thus, legal psycholytic therapy in Switzerland continued until 1993, with efforts to renew the permit currently underway. Thus, we can hope that in the future, psychedelics-assisted psychotherapy will experience a similar renaissance in other countries as well. If so, psilocybin is likely to stand out as the most valuable and beneficial substance, as well as the least risky among the group of possible substances that may be used in this context.

CHAPTER 10

Outlook

Apparently, all of the most important psilocybin-producing European mushroom species are already well known. Their geographic distribution and migration patterns, however, have not yet been adequately investigated. This knowledge gap primarily applies to recently discovered species outside the *Psilocybe* genus. In addition, there is a lack of comprehensive sources of information on distribution patterns of *Psilocybe cyanescens* for a number of different countries.

More Taxonomic, Ecological and Chemical Data are Needed

I would like to suggest that, for most species, even chemical analysis data should be viewed as merely preliminary in nature. In order to learn the truth about these mushrooms and such issues as prevalence, migrations into new habitats, specific positions within the mycological system as a whole, or chemo-taxonomical concerns, we must first acquire more taxonomic, ecological and chemical data from the study of relevant mushroom species. While further analysis of fruiting body samples from known species in order to determine alkaloid content variability remains an essential task, future research must also include efforts to identify secondary substances, as well as their structural isolation. Baeocystin, for example, appears to be an alkaloid primarily found in mushrooms from temperate climate zones, and it is less common in tropical species. Today, there are substantial doubts over whether the synthesis of Baeocystin as described in 1988 is actually feasible. There is an urgent need for additional research on the synthesis of this substance. Possibly, a number of different mushroom ingredients may have psychotropic effects. As such, they could act as modifiers of psilocybin's primary effects in various ways. For instance, accounts of mushroom usage from ancient Mexico already included observations about different types of effect associated with the various mushroom species in use. Perhaps these distinctions are not just the result of different concentrations of psilocybin and psilocin. Moreover, among European and North American mycophiles, the vast majority stress the popularity of *Psilocybe semilanceata*, a species favored over all others, because of its reputation for causing the "richest" kinds of experiences. Indeed, analyses of *Psilocybe semilanceata* extracts typically confirm the presence of eight indole compounds, whereas other species, such as *Psilocybe cubensis*, usually contain only half as many. Understanding just how such ingredients interact with psilocybin may well result in the development of new clinical applications for these substances.

The mycological literature includes information about several rare, if "questionable", species, some of which have been reported to show blue discolorations. The *Mycena* and *Pluteus* genera, for example, include descriptions of such mushroom species. If indole alkaloids were to be found in mushrooms other than the *Agaricales* (gilled mushrooms), it would mean a sensational discovery. Future chemical analyses are bound to identify additional psilocybin-producing mushrooms among the European species, which number about 5,000. There is an even greater likelihood of discovering alkaloids in many non-European species, as the mycofloras of most countries have not been researched as extensively as Europe's.

Understanding the Mushrooms' Powerful Magic

Ethnopharmacological research efforts are also bound to generate remarkable results in the near future. G. Samorini, for instance, recently reported that Catalonia, Spain, is a region where *Psilocybe semilanceata* has traditionally been known by the unusual name of "sorgin zorrotz", or "witches' tread". This label strongly suggests early ritualistic usage of *Psilocybe semilanceata* in that area. Interestingly, Catalonia is also known as Europe's only region where traditional usage of *Amanita muscaria* has been confirmed. In addition, there is growing evidence that other world religions, especially in Africa, have embraced the usage of psychoactive mushrooms as well, an intriguing possibility that calls for further study.

While the number of psychotropic mushroom species has risen dramatically all across Europe, the pace of progress in developing medical uses for mushroom ingredients has not followed suit. However, hallucinogens, including psilocybin have a history of therapeutic usage, a practice that is documented by a great deal of information, experiences and insights.

Given the lack of alternate methods to study these substances, the revival of medical and interdisciplinary research efforts is a more crucially important issue now than ever before. After all, a better understanding of psychotropic substances may well benefit a vast number of patients, possibly by contributing to the processes of mental and psychic healing. A glimmer of hope for the revival of large-scale research comes from the United States, where a very small number of investigators have, on occasion, succeeded at securing government permission to conduct studies on the medical aspects of hallucinogens, including psilocybin. The conceptual approach behind the design of these research projects suggests that virtually no reliable pharmacological data is in existence. In fact, these substances have undergone extensive study over the course of several decades. To the extent that relationships of dosage and effects have already been determined, current and future research efforts should build upon existing knowledge, instead of neglecting or ignoring previously published results. High-tech methodology may well yield new results - techniques for exploring and enhancing our understanding of mushrooms at the biochemical level. But increased biochemical knowledge does not permit us to draw any sort of conclusion about other aspects of psychoactive substances, such as psychedelic peak experiences, exploring the realms of the subconscious mind, as well the development of therapeutic applications based on these effects.

Certain hypnotherapy techniques are known to induce experiences similar, but not identical to, those caused by administration of hallucinogens. Recent studies have demonstrated that hypnosis can benefit the immune system, a finding that suggests psilocybin and related compounds may have potentially similar properties. Meditation and dreaming are additional examples of states of consciousness with interesting parallels to psychedelic experiences, yet very little is known about these links, due to the scarcity of research efforts in this area.

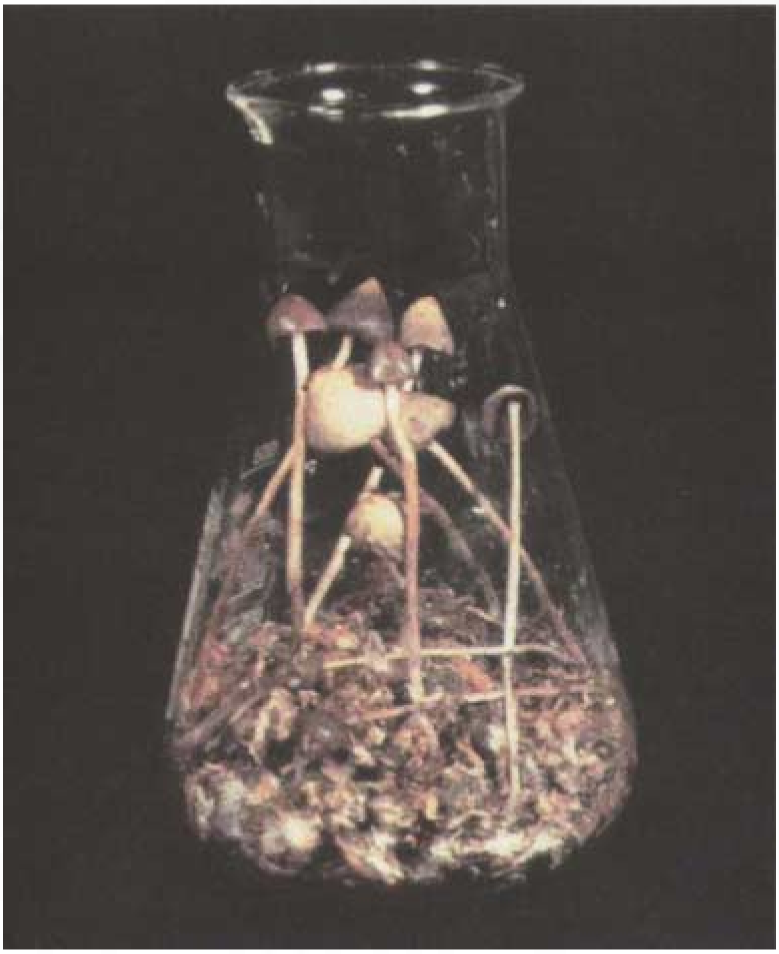

Figure 66 - ***Psilocybe semilanceata*** cultured on a mixture of grass seeds, dung and grains of rice.

In recent years, the non-medical use of psychotropic species has become an increasingly popular pastime. I agree, however, with the assessment of Swiss toxicologist R. Flammer, who has written about the possible problems linked to this practice:

> *"....There is no need to panic, considering the severity of existing problems with alcohol and hard addictive drugs, which make the Panaeolus mushrooms and their close relatives appear harmless by comparison."*

In order to guard against being dazzled or overwhelmed by the mushroom's powerful magic we must embrace the pursuit of in-depth research into hallucinogenic mushrooms, a method that can protect us from jumping to conclusions, and in the process, from hampering the advancement of beneficial applications.

Acknowledgments

I am particularly grateful to Claudia Taake. Without her translation, her technical support and our stimulating, creative discussions, the publication of this book in its present form would not have been possible.

I want to thank Scott Bradbury for his contribution of original artwork on both covers and on page 1, and for assisting with cover design and layout.

I am grateful to several individuals who introduced me to mycology; special thanks are due those who have provided me with a number of extremely rare mushroom samples for my research. I am most grateful to Gerhard Drewitz of Caputh (Berlin) for his helpful observations on the taxonomy and toxicology of the *Inocybe* species. For more than 10 years, he has furnished me with rare mushroom specimens for chemical analyses. I am thankful for our many joint excursions into the world of mushrooms.

Gerd K. Muller (Leipzig, Germany) has deepened my understanding of the mushrooms' purpose and position in the natural world. It was our collaboration at the University of Leipzig, and an opportunity to deposit mushroom material at the Leipzig Herbarium that resulted in the discovery of new frontiers in mycological research.

For contributing valuable data on natural products chemistry, taxonomy and medical applications for psychedelics, I am indebted to the late Marta Semerdzieva, who died in 1994, as well as to Milan Hausner and Josef Herink in the Czech Republic. I cherish the memories of our collaboration and our joint field research expeditions.

I want to thank John W. Allen (Hawaii) for generously sharing many photographs and his expert knowledge of the mycofloras in North America, Hawaii and Asia. I sincerely wish to thank my friends in Switzerland, Rita C. Zengaffmen and Udo Kinzel, for all their contributions. I want to thank Michael W. Smith (Pietermaritzburg, South Africa) for our collaborative field research in South Africa in January, 1994. I am grateful to Paul Stamets (Olympia, WA) for his contribution of mushroom photographs. For their expertise and for providing valuable information I also wish to thank Albert Hofmann, who discovered psilocybin and psilocin (Burg, Switzerland); as well as Jonathan Ott (Xalapa, Mexico); Hanscarl Leuner (Gottingen, Germany); Christian Ratsch (Hamburg, Germany); Alexander T. Shulgin (Lafayette, CA); and Giorgio Samorini (Bologna, Italy).

Finally, my heartfelt gratitude goes to Irmgard Richter, for her years of support and for enduring my unbridled mycophilia.

LIS Publications wishes to thank the following individuals and businesses who have helped make this book possible: Brad Falk, Scott Bradbury, Angelica Biddle, Ronda Flanzbaum, Tim Matthews, David Cronk, Kerstin Taake, FS Books, Knockabout Comics, Mind Books and Rosetta Books.

Bibliography

Considering the vast amount of relevant mycological literature, it makes sense to subdivide citations into categories representing distinct subject areas and specific species and genera. While some entries deal with more than one mushroom species, they are listed only once, under the category heading of the species that is the main focus of the work cited. This will aid in locating citations about specific species, as well as those with a more generalized scope, since titles alone often do not accurately reflect overall content or specific emphases.

Keywords: Psychedelics, Entheogens, Hallucinogens, Consciousness, Perception, Pharmacology, Epistemology, Hallucination, Psychosis, Dreaming, Shamanism, Novelty Theory, Creativity, Nonlinear Dynamics, Chaos Theory

Table of Contents:

Preface
Part I - Psychedelic Information Theory
Chapter 01 - What is Psychedelic Information Theory?
- Why "Psychedelic" Information Theory?
- What is "Shamanism in the Age of Reason"?
- Generic Application, Neutrality, Margin of Error
- Notes and References 1

Chapter 02 - The Value of Psychedelic Information
- The Value of Information
- The Value of Psychedelic Information
- Negative and Positive Information Value
- Notes and References 2

Chapter 03 - Psychedelic Information Theory
- Ingestion
- Internal Transmission
- Internal Integration
- Cultural Transmission
- Cultural Integration
- Psychedelic Information Process
- Notes and References 3

Chapter 04 - What is Consciousness?
- Five Basic Functions of Consciousness
  - *Perception*
  - *Recognition*
  - *Memory*
  - *Recall*
  - *Behavior*

- Operating Properties of Consciousness
  - *Modular Coherence*
  - *Linear Stability*
  - *Feedback Control*
  - *Adaptability*
  - *Self-Awareness*
- Modular Consciousness
- Psychedelic Consciousness
- Notes and References 4

Chapter 05 - Limits of Human Perception

- The Visual Spectrum
- Visual Frame Aliasing
- Visual Frame Resolution
- Dreaming, Imagination, Psychosis, Hallucination
- The Limits of Expanded Consciousness
- Notes and References 5

Chapter 06 - The Control Interrupt Model of Psychedelic Action

- Bottom-up Perception, Top-Down Control
- Constraint, Control, and Feedback Inhibition
- The Control Interrupt Model of Psychedelic Action
- Control Interrupt Envelopes
- Control Interrupt and Shamanism
- Notes and References 6

Chapter 07 - Psychedelic Pharmacology

- Serotonin and the Tryptamines
- Dopamine and the Phenethylamines
- Neuromodulators and Global Brain States
- Molecular Shape, Receptor Affinity, MAO Metabolism
- Breadth of Psychedelic Receptor Binding
- Dissociatives, Anticholinergics, Other Hallucinogens
- Notes and References 7

Chapter 08 - 5-HT$_{2A}$ Agonism and Multisensory Binding

- 5-HT$_{2A}$ receptor mechanics
- Layer V pyramidal cells and perceptual binding
- Destabilization in thalamocortical feedback loops
- 5-HT$_{2A}$ cross-agonism and organism re-modulation
- Notes and References 8

Chapter 09 - What is Nonlinear Hallucination?

- Nonlinear Systems
- Nonlinear Consciousness
- Phenomenology of Nonlinear Perspectives
- Nonlinear Hallucination
- Notes and References 9

Chapter 10 - Entopic Hallucination

- Flicker Phosphenes and Hallucinogenic Interrupt
- Entopic vs. Eidetic Hallucination
- Notes and References 10

Chapter 11 - Eidetic Hallucination

- The Hippocampus, ACh, Memory, and Dreaming
- Anticholinergics, Concrete Hallucination, REM
- Notes and References 11

Chapter 12 - Erratic Hallucination

- Breathing Walls, Melting Textures, Creeping Carpets
- Frame Destabilization and Frame Stacking
- Multisensory Destabilization and Schizophrenia
- Notes and References 12

Chapter 13 - Psychedelic Neuroplasticity
The Case for Psychedelic Neuroplasticity
Physiology of Psychedelic Neuroplasticity
Positive and Negative Plasticity
Tribal Imprinting and Viral Neuroplasticity
Notes and References 13
Part II - Shamanism in the Age of Reason
Chapter 14 - What is Shamanism?
Transformational Plasticity and Imprinting
Shamanic Reputation and Expectant Plasticity
Shamanism, Chaos Magic, and Belief as Toolkit
Shamanic Practice and Seeking Balance
Notes and References 14
Chapter 15 - An Overview of Physical Shamanism
Spirit Voices, Shamanic Songs, and Strange Attractors
Control Interrupt and Spirit Spaces
Driving Interrupt Amplitude and ADSR Transitions
Cellular Automata and Fractal Imprinting
Linear vs. Nonlinear Memory Imprinting
Shamanic Information Compression
Notes and References 15
Chapter 16 - Physical Shamanism and Shamanic Therapy
Modern Shamanic Psychotherapy
Shamanic Dieting, Purging, and Cleansing
Metabolic Destabilization and Cellular Regeneration
Physical Shamanism and Metabolic Entrainment
Notes and References 16
Chapter 17 - Hypnotic Entrainment and Induced Trance States
Neural Oscillators
EEG and Brainwaves
Hypnosis, Induced Trance States, and Entrainment
Shamanic Entrainment Technology
Chapter 18 - Psychic Bonding and Psi
Psychic Bonding and Circadian Rhythms
Stress- and Pheromone-Induced Neuroplasticity
Informational Capacities of Bound Partners
Notes and References 18
Chapter 19 - Group Mind and Fluid Tribal Dynamics
Group Trance and Entrainment Technology
Group Mind and Behavioral Phase Transitions
Informational Capacity of Group Mind
Chapter 20 - Shamanic Sorcery
Sorcery and Nonlinear Influence
Synchronicity Magic and Probability Collapse
Sorcery and Negative Information
Notes and References 20
Chapter 21 - Spirits and Spiritual Communion
Habits and Customs of the Spirits
Interfacing with Spirit Information
Gnosis, the All One, and Nonlinear Communion
Information Capacity of Spiritual Communion
Notes and References 21
Chapter 22 - Information Genesis and Complexity
The Singularity and Post-Technological Matrices
Shamanism and Information Matrices
Notes and References 22

Appendix 01 - Conclusions and Discussion
Conclusions
Discussion
Appendix 02 - Informal Discussion of Topics
What is Psychedelic Information Theory?
How does PIT describe psychedelic action?
How do psychedelic interference patterns relate to the techniques of shamanism and psychedelic therapy?
The Control Interrupt Model reduces hallucinogenic action to a high speed sensory attack and decay envelope. Why did you decide on that model?
Why is a wave model of psychedelic action better than traditional shamanic models?
Doesn't reductive analysis take the mystery or artistry out of entheogenic transcendence and shamanism?
How do psi phenomenon like telepathy and group mind tie into PIT's harmonic wave model?
Can you describe a resonant oscillator? How does harmonic resonance apply to the brain?
So shamanic singing is a form of resonant feedback for stabilizing consciousness in chaotic psychedelic states?
Does PIT present a hallucinogenic scale, like the Shulgin scale, which rates hallucination or expanded consciousness along some metric?
You say expanded consciousness tops out at 16 stacked frames? Why 16 frames?
How do you think PIT will be perceived in the future?
What experiments can be done to test the various models presented in PIT?

About the Author

Preface

Psychedelic Information Theory (PIT) is a formal deconstruction of psychedelic hallucination, expanded consciousness, and shamanism, and as such it attempts to move topics which have traditionally been classified as metaphysics into fields of physics and mathematics. The goal of PIT is to unify all existing psychedelic research into a formal model which accurately describes the complex dynamics generated when a psychedelic drug is introduced into human neural and social networks. PIT is a general model which links psychedelic pharmacology directly to the nonlinear dynamics of expanded consciousness, neuroplasticity, shamanic technique, and tribal organization. This book should be equally enlightening for shamen, physicians, scientists, mathematicians, mystics, and anyone seeking to model or understand the functional limits of expanded consciousness.

PIT is presented as an introductory textbook for people with broad interests in consciousness, perception, psychedelics, hallucination, shamanism, dreaming, pharmacology, neuroplasticity, chaos theory, and related fields. Because PIT is meant to be an overview of a general theory which encompasses many diverse fields, it only scratches the surface of what could be a far larger and more detailed text. Students interested in further exploration on these topics should consult the bibliography and references for more avenues of research and discovery. For readers who are less scientifically inclined, or who seek a quick overview of the concepts covered in this text, an informal discussion of topics has been included in the appendixes. This discussion provides a brief summary of PIT and answers some of the most common questions raised in reaction to the text.

Sincerely,

James L. Kent

Part I

Psychedelic Information Theory

Chapter 01

What is Psychedelic Information Theory?

Psychedelic Information Theory (PIT) is the study of information creation in the human imagination, particularly in states of dreaming, psychosis, and hallucination. PIT seeks to model the functional output of human perception in order to extrapolate the limits and complexity of information arising in human altered states of consciousness.

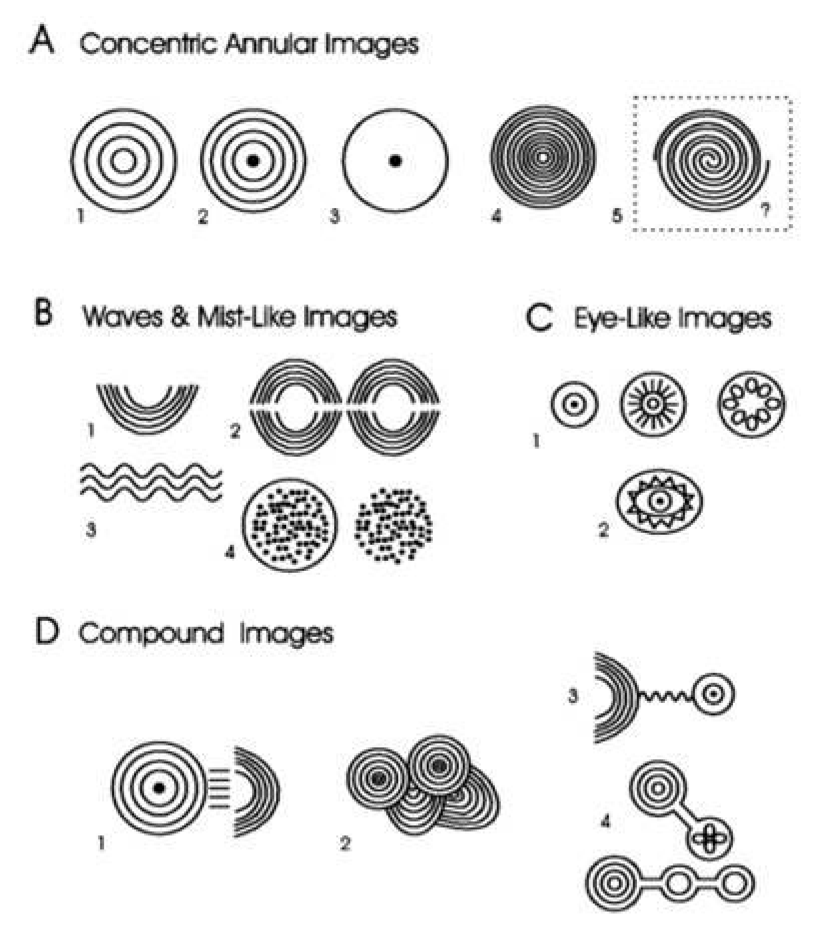

Figure 2. Images of internally generated sensations of light (phosphenes) with geometric shapes and no memory-based content, found in ethnographic reports and prehistoric rock art studies. From Nicholson and Firnhaber.

The foundation of PIT lies in novelty theory, the study of increasing complexity of information over time. Novelty theory encompasses a large time-scale, but PIT is specifically focused on the spontaneous production of complex information in the human organism, which is also known as creativity theory or generative theory. Modeling the creation of information in the human brain requires formal definitions for perception, consciousness, and information, and as such PIT is also a work of systems theory, which posits that the potential output of any system can be fully described by the functional limitations of its components. PIT also draws on control theory, which models the stability and complexity of signal processing in dynamical systems. By applying control theory and systems theory to altered states of consciousness, PIT is an analysis of the nonlinear dynamics of hallucination and expanded states of consciousness. And finally PIT draws upon the fields of wave mechanics, neural oscillators, neuroplasticity, and the fundamentals of pharmacology, cognitive theory, and neural signaling as they apply to perception, memory, and consciousness; this also makes PIT a text on multidisciplinary neuroscience.

Why "Psychedelic" Information Theory?

The bulk of human consciousness exists in a linear range which goes from highly focused and alert to deep asleep and dreaming. Most states of consciousness are experienced uniformly and independently of each other along this linear spectrum. For instance, when you are asleep you are not awake; when you are focused you are not daydreaming; when you are anxious you are not relaxed. The fact that consciousness exists in only one state at one time is an indication that the system is linear and stable. When two distinct perceptions or states of consciousness overlap at the same time this is an indication that the system is unstable, and in most cases where divergent states of consciousness overlap the output is viewed as a pathology.[1] State-divergent pathologies are typically treated with drugs targeted to amplify the positive traits and/or dampen the negative traits.

The term psychedelic means "mind manifesting," which implies that all potential states of mind may be manifested under the influence of psychedelic drugs. If normal consciousness moves in a straight line along a spectrum of many possible states, psychedelics represent a unique and reversible destabilization of this linear spectrum where consciousness can assume multiple points of consciousness simultaneously. The most extreme divergent state of consciousness is described as being wide awake while simultaneously dreaming, a state clinically referred to as psychosis or hallucination. The emergence of multi-state consciousness under the influence of psychedelics represents a system that has destabilized from linear output and has become nonlinear and exponentially complex. Thus, in psychedelic perception the linear functions of consciousness diverge into a complex nonlinear state where multiple perspectives and analytical outputs may be experienced simultaneously.[2] According to PIT, this destabilized state of nonlinear complexity is where new information is generated in the human mind. Understanding the dynamics of this unique nonlinear function is essential to understanding the informational limits and potential complexity range of all human consciousness.

What is "Shamanism in the Age of Reason"?

PIT seeks to describe a model of psychedelic activation that can be adapted to all possible permutations of human consciousness, including group mind states, mystical states, and transpersonal awareness. The ritual of using psychedelics to generate new information, bond with peer groups, and program human belief is traditionally called shamanism, so PIT is a study of the practice of shamanism, which can also be called applied psychedelic science. The practice of using ritual techniques of spiritual transcendence to manipulate belief systems has been popularly dubbed chaos magic, which is an occult blend of neo-shamanism, cognitive theory, and social theory (Fig. 3). Chaos and complexity are also popular terms applied to the study of nonlinear systems, such as fractals and cellular automata, making chaos magic and shamanism spirituo-scientific explorations of the generative function of nonlinear systems.

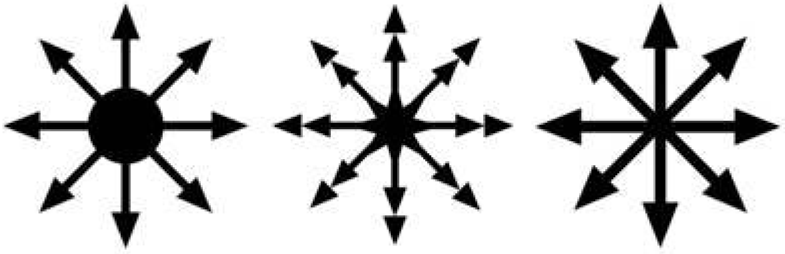

Figure 3. The eight-pointed star is a popular symbol of chaos magic. The arrows represent energy, or information, scattering at high velocity. This symbol is isomorphic of a nonlinear information system, like a universe, which starts at a single point and erupts outward in all directions.

While PIT focuses on physiology over mythology, it is clear that there is a fundamental human desire to achieve states of consciousness subjectively described as Gnostic or spiritually enlightening. It is the conjecture of PIT that all mystical states, including healing and regenerative states, have unique formal nonlinear qualities that can be described in physical terms close enough to make good approximations. This means that PIT is also a work of technical shamanism, neurotheology, or spiritual neuroscience, and can be referenced in the clinical application of psychedelic drugs in shamanic ceremony, mystical ritual, or psychedelic therapy.

Generic Application, Neutrality, Margin of Error

PIT does not attempt to provide precise definitions of consciousness, perception, or the psychedelic state. Instead PIT attempts to model an approximation of psychedelic consciousness based on the known functions and limits of human perception and cognition. According to PIT, if a functional reproduction of consciousness existed then it too could be made to have a psychedelic experience. This also makes PIT a text on artificial intelligence which can be tested in mechanical systems of perception. While this text may contain some assumptions and conjecture on human brain function, the fundamentals of PIT are generic enough to apply to any system of consciousness which relies on real-time frame perception for interacting with reality. Although the bulk of the text focuses on states of hallucinogenesis afforded most readily by the tryptamines LSD, psilocybin (magic mushrooms), and DMT (found in the South American brew ayahuasca), and their action at the 5-HT$_{2A}$ receptor subtype, PIT strives to be generic and substance neutral, meaning that the fundamentals of PIT should apply to all drugs and techniques which produce hallucination, even though they may target different receptors and/or destabilize consciousness in a wholly unique way.

Notes and References 1

1. Some examples of pathologically divergent states of consciousness: Asleep and active is sleepwalking; excited and drowsy is narcolepsy; awake and rigid is Parkinson's Disease; awake and dreaming is psychosis; relaxed and nervous is anxiety disorder; fulfilled and sad is depressive disorder; and so on.
2. When a linear function diverges or bifurcates and begins plotting a range of multiple outputs for the same input, this can be called unstable, dynamic, nonlinear, complex, higher dimensional, undefined, and so on. It depends on how you model your system.

Chapter 02

The Value of Psychedelic Information

A text called *Psychedelic Information Theory* raises the question, "What is Psychedelic Information, and why should we care?" Generally, psychedelic information is any information created in the mind of the subject during a psychedelic experience. Psychedelic information is generated spontaneously in reaction to the psychedelic catalyst; typically the subject has little or no control over the information generated in a psychedelic experience. Psychedelic information is almost always previously unknown to the subject and may appear to originate from an external source or materialize out of thin air. Psychedelic information typically takes the form of visual, audio, and sensory hallucination, but can also be abstract or gestalt like an emotional epiphany. Finally, psychedelic information applies to any art or concept that originates from or evokes psychedelic experience.

This text focuses primarily on the physiological process underlying the spontaneous generation of psychedelic information, and how that information influences both personal and cultural identity. The fact that psychedelic information makes its way into popular culture is proof that humans find psychedelic information valuable, but it is still ambiguous if psychedelics add any real value to culture. Research has shown that spiders are affected by psychedelics,[1] as are rats,[2] cats,[3] monkeys,[4] and so on. However, there is little evidence that information other than noise is generated during psychedelic episodes in animals; the experience does not mean anything beyond a specific derangement of the senses. In contrast, the human adaptation to translate subjective experience into meaningful narrative is uniquely exploited by psychedelics. Psychedelics target perception, memory, and the complex emotions attached to symbols and concepts; the core functions humans rely on to formulate belief. Because of this exploit, the result of the psychedelic catalyst in humans is the spontaneous generation of meaningful information which is imprinted into memory.

Any perceptual system can have a psychedelic experience,[5] but it takes abstract thinking and the interconnection between symbols, concepts, and emotions to make psychedelic information meaningful. Thus, the psychedelic experience does not create information in all systems of consciousness; the psychedelic experience only generates meaningful information in systems of consciousness with the capacity for abstract reasoning via symbolic logic and emotional attachment. Presumably any conscious system which emulates the functions of human abstract reasoning will also similarly generate meaningful information during a psychedelic experience.

The Value of Information

Within the set of information valuable to humans there are domains of descending importance. First there is information valuable to all organisms (biological information), then there is information valuable to all humans (species information), then there is information valuable only to a specific local group of humans (cultural information), and then there is information valuable only to a single human (personal information). All biological information and the most important bits of species information are genetic and are preserved through natural selection. Within the domain of human species importance there is also technological information (such as fire, tools, language, music, agriculture, science, etc.) which are culturally agnostic and serve the needs of the entire species equally. Technological information of species-level importance is equated with high value and will be adopted by all cultures over a short period. Species-level information has high durability and changes very slowly over time.

Cultural information falls in the category of language-based memes and regional or tribal traditions. Cultural information may be shared across cultures or may be restricted to a specific region or subculture. Cultural information is considered to be of medium value, low durability, and changes rapidly over time as the memes and traditions of culture change. Religion and artwork are examples of cultural information that typically only have value to their culture of origin, but occasionally ascend to species-level importance. Finally there is personal information, which is valuable only to a single individual. Personal information changes rapidly, is subject to experience and whim, and is only useful over the lifetime of the organism. Personal information has very low durability and low overall value.

The Value of Psychedelic Information

Psychedelic information is generated within the domain of the personal; yet many people who take psychedelics perceive the information as having species-level importance. There are a few reasons for this phenomena. The first, and easiest, is that psychedelics create states of mania and delusions of grandeur in which the subject feels that he or she is the most brilliant person on the planet, or that they are receiving supernatural prophecy. Secondly, the subject may experience archetypal visions or sensations of transcendence that are perceived to be of high religious or mystical importance. Thirdly, the subject may experience a deconstruction of consciousness associated with animal consciousness, reptilian consciousness, plant consciousness, the Gaian mind, genetic-level intelligence, or deep species memory; information perceived to be of value to all humans or all living creatures. Because psychedelics produce all of these experiences they are routinely perceived as having species-level importance.

Psychedelics are obviously useful in the domain of the personal; shamanism and psychedelic therapy rely on the information function of psychedelics to diagnose and heal. In the cultural domain psychedelics can be employed in ritual to build strong religious or tribal groups; they can be used in healing or sorcery; or they can be a catalyst for innovation and creative expression. Beyond this their value is ambiguous. There are some debates to be made in this area, such as pointing out that Francis Crick envisioned the spiral structure of DNA after he ingested LSD,[6] or that LSD helped Kary Mullis think up the PCR process that earned him a Nobel Prize in genetics.[7,8] To counter these arguments, both Crick and Mullis had been studying molecular biology for years trying to crack those very problems; LSD cannot take credit for anything more than helping Crick and Mullis organize their thoughts in a new way. We can point to great discoveries as examples of psychedelic information, but only a tiny fraction of all psychedelic information can claim this level of importance. Worse than this, erroneous psychedelic information claiming species-level importance has negative cultural value and dilutes the overall information marketplace, making psychedelic information almost statistically worthless.[9]

Probability dictates that most psychedelic information will have little or moderate value, and that the rare piece of psychedelic information will have extreme negative or positive value. It also follows that the more times a subject takes psychedelics the more likely it is they will generate information of high positive or negative value. Similarly, the more often a subject takes psychedelics the more likely they are to latch onto and subsequently reinforce information of high perceived value, either positive or negative. In this case the psychedelic becomes an information imprinting tool. In psychedelic imprinting the information is always subjectively perceived to be of high value, even if it is of low or even negative cultural value.[10]

Negative and Positive Information Value

It is easy to demonstrate that psychedelic information has value; cultures that use psychedelics as sacraments place high value on the information they receive; people will trade hard-earned cash for a psychedelic experience. But because the quality of psychedelic information has such a wide range it is easy to perceive psychedelics as having no value or, in the argument of prohibition, negative value. Psychedelic information with negative value can be described as that which is delusional, paranoid, false, or subverts the health of the individual or culture. Negative psychedelic experiences, or bummers, are a commonly reported element of psychedelic experimentation, but this does not necessarily make bummers negative. Some users claim that negative experiences have value because they provide emotional insight; others report that negative psychedelic experiences cause permanent psychological damage, which is extremely negative. In rare cases people act out and harm themselves or commit suicide on psychedelics. Obviously these are extreme examples of negative value, and these extreme examples are usually linked to mixing drugs, drug binging, or overdosing. There is an optimal dose range for any psychedelic substance; reports of negative effects increase once the optimal dose range is surpassed.[11]

Conversely, there is a range of psychedelic experience that is just as extreme but positive in value; the spiritual or therapeutic or entheogenic experience that adds value to the user and their culture. Having an extremely positive psychedelic experience does not happen by accident; there is nuance involved in selecting the proper dose, finding the right setting, and so on. By contrast, having a negative psychedelic experience is almost always an accident due to improper dose or setting. Therefore, the positive value of a psychedelic experience can be predicted and controlled up to a certain dose range, but beyond that the potential positive value drops and potential negative value increases.

Shamanism, which for the purposes of this text is defined as the practice of using psychedelics in ritual, employs specialized techniques to guide psychedelic information along desired pathways. Influencing and imprinting psychedelic information along positive pathways is perceived as spiritual, enlightening, and therapeutic; influencing or imprinting psychedelic information along negative pathways is perceived as mind control, black magic, or sorcery. Although the value of psychedelic information generated in any single episode is ambiguous, the practice of shamanism is a durable technology with species-wide application. Thus, shamanism is a technological subset of psychedelic information with high value to the entire species, even though the practice of shamanism can be employed to both positive or negative effect.

9. The psychedelic community produces a new guru every decade or so, and the cultural contributions of these gurus trends from pseudo-scientific to outright fantastical. It is often difficult to tell if the contributions of psychedelic celebrities outweigh the more nonsensical memes they propagate.
10. Psychedelic imprinting can take many forms, and in some cases negative information can be imprinted into identity. Brainwashing is the act of imprinting another person against their will, which is viewed as negative. Self-brainwashing is the act of imprinting yourself with negative information either by choice or error. In self-brainwashing negative information typically assumes explicit paranoid or messianic themes. Extreme cases of psychedelic self-brainwashing will mimic elements of psychosis and persistent delusional disorder. See Chapter 13, "Psychedelic Neuroplasticity".

Chapter 03

Psychedelic Information Theory

Like dreams, psychedelics are catalysts for generating information in the human imagination. There are many theories about the origin of this information: the subconscious; repressed emotions; the collective unconscious; genetic memory; spirit entities; alien transmission; junk data from neural excitation; and so on. Regardless of the origin it is widely accepted that psychedelics do generate information, and not merely junk data of questionable value. Psychedelics excel at producing salient information which can have a profound impact on the beliefs and identity of the subject.

The information generated by psychedelics is usually personal, but it can become transpersonal as psychedelic insights are shared with friends and the public. The rate of psychedelic information flow can be measured by the amount of explicit influence psychedelics have over any given culture, and the rate of flow is different for every culture. Some cultures repress anything resembling psychedelic information while others make it central to their spirituality.[1] Since the cultural revolution of the 1960s, psychedelic information flow has erupted into Western culture at an unprecedented rate. This rate of modern psychedelic information flow has had its ups and downs, but overall has remained relatively constant even in the face of global prohibition.[2]

The pathway of psychedelic information flow is simple and universally the same: 1) ingestion; 2) internal transmission; 3) internal integration; 4) cultural transmission; 5) cultural integration. Most psychedelic research focuses solely on internal transmission, the second stage of the psychedelic information process which is commonly called the trip. While the trip is certainly interesting it is still only one part of the larger overall process by which psychedelics influence both the individual and culture. Each part of this information process has its own patterns and predictable stages, and different portions of this text will attempt to illuminate one or more of these stages in the service of providing an overall understanding of how psychedelics impact culture. Below is a capsule summary of each stage in the psychedelic information process.

Ingestion

While it is difficult to define why people choose to take psychedelics, each society has its own rules which dictate who is allowed to ingest a psychedelic drug and in what context. In traditional settings ingestion is a spiritual exercise used to gain supernatural wisdom, and dosage is controlled ritually by the shaman. In modern Western culture the traditional rules have broken down and psychedelic ingestion has become complex and somewhat haphazard. In a modern context most people are introduced to psychedelics in mundane recreational circumstances, motivated by hedonism, curiosity, boredom, peer pressure, or rebellion. Sometimes an innate hunger for the mysterious drives ingestion. Typically the psychedelic user is seeking something, however vague that notion.

Internal Transmission

Internal transmission is where the psychedelic interacts with the neural network and new information is generated. Information in the psychedelic state is generated spontaneously within visual and audio hallucination; ideas which pop into the subject's imagination; novel juxtapositions of previous concepts; and removed perspectives that allow for new holistic analysis. This information can be literal or figurative; it can be abstract; it can come in words or phrases; it can be spoken or sung; it can be visual; it can emerge as epiphanies or brilliant ideas; it can be a recalled memory; it can be delivered by spirit entities in strange languages; and so on. The information density in a psychedelic session is layered, saturated, and colorfully detailed. Much of the information in a psychedelic hallucination may be accurately described as kaleidoscopic noise, but within this noise comes a wealth of salient content.[4]

In physical terms psychedelics create new information via spontaneous activation and organization of sensory and perceptual networks. Psychedelic information is experienced via direct neural firing and is transferred to memory via the creation and strengthening of synaptic connections in the neural network.[5] Psychedelic information generation takes energy, and the information processing capacities of the human brain are finite, and thus there is an upper limit to the amount of information that can be generated within a single psychedelic session before the brain begins to down-regulate in an attempt to return to baseline.[6]

Internal Integration

For many reasons there is loss of fidelity in the transmission of hallucinatory information from imagination into memory. Like a dream, memories of the psychedelic session must be compressed into manageable snippets that stand out within the larger wash of information. Although psychedelic hallucinations fade quickly they can have lasting emotional impact. How each person deals with the content of each experience is unique to their world view. Some people may choose to ignore content derived from the psychedelic experience; others may cherish anything they can remember and will scrutinize each vision in pursuit of higher metaphysical truth. During this process the information generated during the psychedelic trip is encoded into personal memory by forging and testing new synaptic pathways.

During post-psychedelic integration the subject may begin to reassess and modify personal beliefs and behaviors. Cryptic and intense visions may be recalled over and over, or the subject may dwell obsessively on novel feelings experienced during their trip. The subject will typically review their psychedelic trip and create a lasting narrative of the journey, including what they experienced and what they learned. Integration is where the subject decides what happened in the experience. The content of the hallucination is not as important as the process by which the subject takes that content and shapes it into lasting memories, beliefs, and behaviors; this is the process of encoding psychedelic information into synaptic networks. Content generation without behavioral integration is essentially meaningless, so the true testament of psychedelic power is not the ability to produce visions, but the ability to imprint new information and transform belief.

Cultural Transmission

Psychedelic visions do not stay in the head; if they did there would be no psychedelic art, no psychedelic music, no psychedelic spirituality, and no psychedelic revolution. Psychedelics activate a process in which the realm of the psychological spills out into the realm of the physical. It is clear from 20th century history that psychedelics can fuel artistic expression, social experimentation, religious movements, and political activism. There is no other class of drugs which can claim to have such powerful cultural sway.[7] If psychedelics only produced hallucinations there would still be legitimate cause for fascination, but psychedelics also influence cultural movements, which makes them a global religious and political force to be reckoned with.

The ritual bonding of social groups through cultural transmission of psychedelic information is a subject that has been overlooked in almost all psychedelic research. Not only do psychedelics produce change at the individual level, they also produce changes at the group or tribal level, and thus they influence change in the social structures and goals of human culture. The spread of psychedelic information can be subtle or explicit, starting with the creation of art influenced by the psychedelic experience and culminating in the indoctrination of others into the psychedelic tribe through ritual sharing of the sacrament. Once a subject has been indoctrinated they too will spontaneously generate psychedelic information and begin sharing that information with others. This information process cascades from person to person until the cultural transmission of psychedelic memes reaches a tipping point and becomes openly adopted and even celebrated by the cultural mainstream.

Cultural Integration

By conservative estimates perhaps 10-15% of the population has ever tried a hallucinogen.[8] Despite such low levels of exposure the archetypes of psychedelic experience are well integrated into modern culture. Psychedelic subcultures (urban tribes) are active in every city on the planet. Annual psychedelic festivals, raves, and massives draw tens of thousands of people together from all continents.[9] Psychedelic influences appear constantly in modern fashion, music, visual arts, film, television, consumer products, marketing, packaging, advertising, videogames, and so on. Despite years of prohibition the promise of psychedelic spirituality and psychedelic therapy is still fresh in the public imagination.[10] The global cultural integration of psychedelic information may not be complete, but it is measurably on its way.

It has only been 50 years since the cultural revolution of the 1960s, and the speed with which psychedelics have influenced global culture is impressive. Over the decades the use of psychedelics has jumped generations, and each new generation rediscovers and repurposes the psychedelic ritual for its own needs. There are religious and political forces actively seeking to control or stop the use of psychedelics, but if current trends continue the complete cultural integration of psychedelic information seems inevitable. There may soon come a time when the global majority is in the psychedelic tribe, with the uninitiated minority self-excluded from the ritual. When psychedelic indoctrination reaches a majority of any population then that culture can be described as being saturated with psychedelic information. A culture that has become saturated with psychedelic information will naturally recognize psychedelic ritual as a legitimate rite of passage or spiritual practice.[11]

Psychedelic Information Process

The psychedelic information process is an observable phenomenon that has influenced cultures throughout history and is now affecting modern global culture. At the center of this information process is the pharmacological action of a small number of molecules hitting a tiny subset of neural receptors for a relatively short duration of time. The ongoing information process generated by this small pharmacological interaction goes far beyond the normal range of what we expect drugs to accomplish. Because psychedelics defy pharmacological rationality they are misunderstood, feared, and revered as spiritual in origin. This misunderstanding drives the psychedelic information process into divergent streams of theory and mythology, creating the tapestry of psychedelic propaganda, confusion, and disinformation we have today.

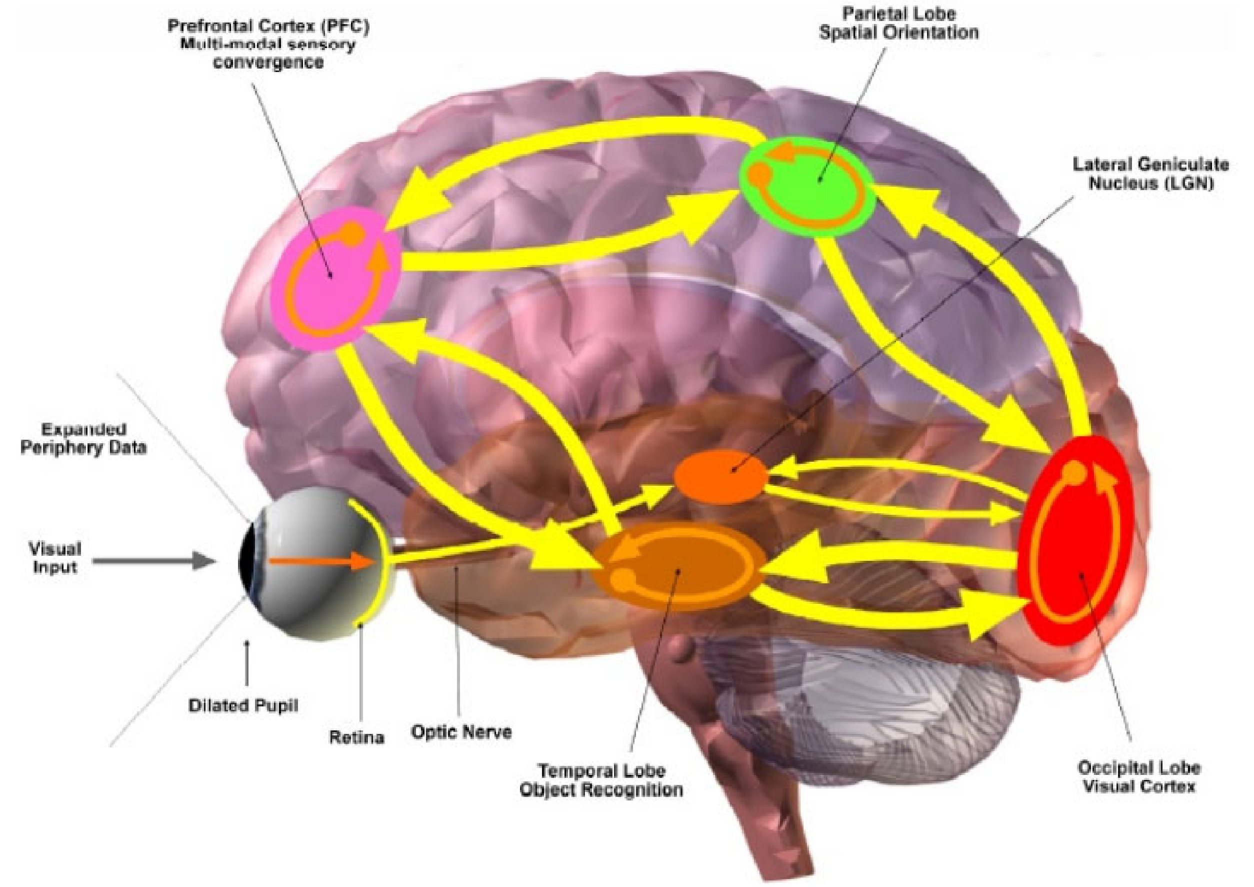

Figure 4. Feedback circuits in visual perception pathways. Sensory signal in human consciousness projects up and around the brain like a wave as consciousness arises in distinct stages. Sensation begins with the sensory organs and feeds into the thalamus (through the LGN for visual pathways), which filters and routes sensation into higher areas of the cortex. Recognition happens quickly and instinctively in the thalamus and medial temporal lobe, focusing attention on salient information. Memory identifies incoming signal moving upward in the cortex, passing data through parallel layers of spatial and object recognition along dorsal and ventral pathways. Multisensory perception finally converges in the pre-frontal cortex as a parsed reconstruction of reality is presented for informing real-time behaviors.

The divergence of psychedelic information and existence of competing schools of psychedelic ideology demonstrates there is no one objective and true psychedelic ideology; any ideology can be influenced and amplified by the psychedelic information process. The psychedelic information process is neutral and ideology non-specific; it applies equally to learning, creativity, mind-control, brainwashing, mysticism, sorcery, and healing. The psychedelic process and psychedelic archetypes can be co-opted by any religious or political group for personal power gain, and psychedelics can be used as weapons as easily as they can be used as medicines or sacraments.[12] The only constant between all divergent schools of psychedelic ideology is the physical process that stimulates the flow of novel information through human neural networks. The study of this information process is known as Psychedelic Information Theory.

Notes and References 3

1. Psychedelic information flow within any culture is a function of religion and politics. Traditional shamanic cultures value psychedelic information as a ritual form of bonding, healing, and discovery, and encourage psychedelic information flow. Industrialized cultures with centralized beliefs view psychedelic information as subversive and anti-authoritarian, and repress psychedelic experimentation out of fear of losing centralized control.
2. A close scrutiny of late 20th century history indicates that there was a small decline in psychedelic interest in the late 1970s and 1980s, followed by a global resurgence of underground psychedelic interest in the 1990s, and a complete return to psychedelic research at the turn of the 21st century. Prohibition may slow the flow of psychedelic information, but it does not stop it.
3. *footnote absent*
4. The content of psychedelic hallucinations has been described vividly in many places. See "Tripping" by Charles Hayes, or the Erowid.org Experience Vaults for hundreds of fascinating first person accounts.
5. See Chapter 13, "Psychedelic Neuroplasticity".

9. Modern psychedelic festivals can be traced to the "Be-ins" and "Acid Tests" of San Francisco in the late 1960s, made famous by Tom Wolfe's "The Electric Kool-Aid Acid Test". These festivals evolved into Woodstock, the Grateful Dead circuit, the Rainbow Family, Rave culture, Burning Man, the Boom Festival, the Love Parade, and other gatherings around the world dedicated to psychedelic music, art, and culture. Attendance at the largest of these annual festivals is regularly in the tens to hundreds of thousands of people.
10. The 2006 psilocybin and mysticism study by Roland Griffiths brought new enthusiasm to mixing psychedelic spirituality with clinical therapy.
11. It is easy to claim that traditional tribal societies are saturated with psychedelic information, but modern society is not far behind. Western media is filled with psychedelic imagery and fascinated by altered states. In the United States, ayahuasca and peyote are already recognized as legitimate religious sacraments within specific churches, and psychedelic drug experimentation is a common rite of passage among university students.
12. Groups linked to the weaponized use of psychedelics include the Manson Family, the SLA, Aum Shinrikyo, the CIA, and the United States Department of Defense.

Chapter 04

What is Consciousness?

Since this text is about the manipulation of consciousness it is beneficial to have working definition for this term. Consciousness is defined here as a dynamical information processing system with specific functions and emergent operating properties, all of which are necessary to maintain system stability.[1] The minimum specific functions for any conscious system are: 1) perception 2) recognition 3) memory 4) recall, and 5) behavior. The minimum specific operating properties for any conscious system are: 1) modular coherence 2) linear stability 3) feedback control 4) adaptability, and 5) self-awareness. When all of these functions and operating properties are working in tandem you get something resembling human consciousness.[2] When one or more of the five essential functions is degraded then consciousness slides into semi-conscious, subconscious, or unconscious modes. When one or more of the five operating properties is degraded then consciousness becomes unstable and loses fidelity. A description of the functions and operating properties of consciousness follows.

Five Basic Functions of Consciousness

All conscious systems rely on five basic functions to interact with the environment in real time.

Perception

A conscious system must receive input, this input is called perception. For humans, perceptual input is received as sense data moving towards the brain from the peripheral nervous system. Sensation does not become actual perception until it is routed up through the thalamus and into higher cortical areas for processing. Humans also perceive internal thoughts and feelings, their own external behaviors, and small pieces of their dreams. Perception is linear, it feeds back on itself through behavior and recall, and its primary function is to observe changes in environment over time. Errors in human perception are sometimes called hallucination.

Recognition

Data from perception is parsed and matched against known salient patterns; this process is called recognition. Human recognition is driven by hormonal reaction to salient patterns; patterns which have high emotional resonance. Human recognition utilizes fast nonlinear analysis over slow semantic analysis. Fast recognition has high utility but low fidelity, meaning it works quickly but must be double-checked by linear memory for accuracy. Recognition is contextual, multisensory, associative, and its function is to find salient data in incoming perception. Nonlinear recognition errors include false identification, misrepresentation, and déjà vu.

Memory

All salient patterns are stored in memory. Patterns stored in memory are matched against incoming data for recognition; they are also matched against possible solutions for recall. In humans memory is imprinted by emotional resonance, reinforced through linear repetition, and potentiated though nonlinear contextual association. Human memory has many layers; semantic, eidetic, associative, and potentially holographic. Multi-layered human memory involves longterm potentiation and lossy compression, but this compression also includes indexing redundancy to serve fast recall and recognition of salient data.

Recall

Recall uses associative patterns stored in memory to make informed decisions based on logic. Unlike recognition, which is spontaneous and intuitive, recall uses negative feedback to inhibit detrimental solutions and positive feedback to stimulate advantageous solutions. Recall is cyclical and associative, meaning it can use both negative and positive feedback to cycle through and evaluate many hypothetical scenarios before resting on a final decision.[3] The main function of recall is to analyze patterns stored in memory to inform intelligent decisions and behaviors in real time.

Behavior

A conscious system performs behaviors based on input. Human behavior takes the form of both internal and external actions. Internal behaviors, such as thinking thoughts and feeling emotions, transform memory and recall into logical decisions; external behaviors translate internal decisions into outward actions. Human behavior is linear and serial; behaviors are performed in sequence one at a time, typically with thoughts and emotions preceding and informing the intent of action. Both internal and external behaviors feed back into perception, closing the loop on the perceptual feedback process.

Operating Properties of Consciousness

When all of the functions of consciousness are up and running the system begins to take on certain familiar operating properties. These basic properties are what we would expect from any conscious system, and any conscious system that loses these properties will also become unstable and lose fidelity of perception and memory.

Modular Coherence

In order to perform like a seamless, integrated system, consciousness must have some means of synchronizing performance between modular sub-functions. Functional cooperation between different areas of the brain is measured in terms of coupled neural oscillators, neural spike synchrony, and coherence of network oscillations.[4] Waking consciousness oscillates within the alpha and beta ranges; high frequency gamma coherence is associated with the fast binding of cortical networks necessary for perception and consciousness.[5] Modular coherence is the first operating property of a conscious system; precise timing between all areas is necessary for multisensory integration. Without coherence the modular subfunctions of consciousness lose interoperability and destabilize.

Linear Stability

Consciousness can perform many different functions, but it only performs one function at a time. The functional range of consciousness is linear and moves predictably from state to state with the passage of time. Consciousness transitions seamlessly from one behavior to the next. Consciousness retains state data and reacts logically to environmental change. In conscious systems the perception of the passage of time remains constant. The ability to remain focused on the environment and perform sequenced, goal-oriented behaviors in realtime is an operational baseline for all conscious systems.

Feedback Control

Conscious systems must be able to monitor and control their own stability and perform behaviors to modulate system input and output. All conscious systems must have some form of feedback control to retain object focus, retain state data, refine behaviors, perform state transitions, and maintain linear stability. Without feedback control, a dynamical information processing system is prone to output exuberance, memory overload, and error.[6]

Adaptability

A conscious system must be able to store patterns, predict outcomes, learn new behaviors, and react to external variable change. Adaptability and the ability to learn from experience is an epiphenomena or spontaneous operating property of a functionally stable consciousness. Intelligent systems that do not exhibit adaptability only mimic some of the functions and properties of consciousness without actually achieving full consciousness.

Self-Awareness

A conscious system must be aware of itself and be able to recognize other conscious systems. Self-awareness is an epiphenomena of the functions and properties of consciousness maintaining linear stability through time. Self-awareness and the ability to recognize and interact with other conscious systems may be the truest and most objective test of any stable consciousness.

Modular Consciousness

The most dramatic way to demonstrate the fragility of consciousness is to lose it. We sleep every night, and sleeping is a very limited form of consciousness where most of the functions and properties disappear. When we sleep we cannot hold state information from one moment to the next, thus we lose contextual data and self-awareness. In dreams we have perceptions and perform behaviors, but they are not linear nor do we have much control over them. In deep sleep all functions of consciousness go offline and almost entirely shut down. When we wake up these functions slowly return and then restabilize into an alert waking mode. Consciousness turns itself off; consciousness turns itself back on.

Sleeping and dreaming demonstrate that the basic functions of consciousness are modular and interdependent; they can operate individually as well as in specialized groupings. The modular functions of consciousness can be switched off and on in any order without affecting the long-term stability of the fully operational system. The modularity of consciousness becomes evident in cases of brain trauma or mental illnesses where the subject loses some functions of consciousness but retains others.[7] When consciousness is stable we cannot tell it is modular; it runs as a seamless whole or an integrated system. When consciousness destabilizes the modular units uncouple and reveal themselves to be sub-personal pieces of a larger identity process. The loss of multisensory perception and the splintering of consciousness into multiple independent processes can accurately be described as an altered state of consciousness.

Psychedelic Consciousness

If consciousness is modular and the modular functions can interoperate in multiple configurations, it is reasonable to assume there are multiple configurations of sub- and meta- consciousness that are rarely explored. The linear states of consciousness we experience daily are controlled by a top-down homeostatic regulator,[8] but when we short-circuit this regulator we find that modular sub-functions of consciousness can be destabilized, uncoupled, and accessed in novel ways. All forms of mysticism rely on radical destabilization of homeostasis.[9] EEG studies of subjects with hallucinogen persisting perception disorder (HPPD) have shown that when the visual cortex loses coherence with other areas of the brain and coherence among local visual networks increases, spontaneous hallucinations are produced.[10] Sensory deprivation for as little as fifteen minutes is all that is necessary to uncouple the visual cortex and have it start producing coherent self-sustaining hallucinations.[11] This can be described as sleep onset visualization, similar to daydreaming or lucid dreaming, and is sometimes called the prisoner's cinema because extended periods of solitary confinement also produce this effect, as does macular degeneration of the retina. This demonstrates that when modular functions of the brain are uncoupled from top-down coherence they do not always disappear, they may also spontaneously organize into more locally coherent configurations. This uncoupled and locally coherent activity can produce wandering or non-linear sensation in lower brain areas which floats up to conscious awareness as linear perception. This is a neat formal definition for states of dreaming, creative visualization, and hallucination.

Psychedelic Information Theory posits that the uncoupled sub-functions of modular consciousness, acting either alone or in novel peer groupings, are responsible for the subjective altered states classified as hallucinogenic, dissociative, and psychedelic. All hallucinogens must first destabilize top-down coherence of consciousness to produce novel states of spontaneous organization between the modular sub-units; this is how all hallucination begins. Dissociatives disrupt top-down coherence by blocking the excitatory pathways that allow the modular units to communicate. Psychedelics have a more subtle effect on top-down coherence; they periodically interrupt or excite the modulatory frequency of multisensory frame binding, causing perception to destabilize into energetic nonlinear configurations.[12] By destabilizing the top-down control of consciousness, psychedelics allow the modular sub-functions to wander and/or interact with coupled peers in dedicated subsystems; similar to the dedicated circuit created between perception and memory when dreaming.

Destabilizing or splintering consciousness into novel configurations is the essence of psychedelic exploration. When consciousness bifurcates or splits, subjective perception instantly becomes more chaotic and complex. Splintered consciousness may actually appear to be in two places at once, stuck in a superposition between waking and dreaming, finding stability in two simultaneous perceptual states, also know as multi-stability a multi-stable state. Novel configurations of splintered or multi-stable consciousness can be described as nonlinear, complex, meta, transpersonal, depersonalized, faceted, holistic, higher-dimensional, expanded, mystical, subconscious, semi-consciousness, and so on. Splintering, re-configuring, and rebuilding the modular subunits of identity are techniques that may be applied in brainwashing or meta-programming,[13] but also fall under the rubric of mysticism and shamanism. By subverting and re-organizing the modular functions of linear consciousness, psychedelics expand the functional range of consciousness to include many novel states of multi-stable complexity. These complex perceptual states, also known as expanded states of consciousness, are the origin of hallucination and the source of all the psychedelic information that has influenced human mythology, religion, art, science, and culture.

Notes and References 4

1. There is a popular school of thought which posits that consciousness precedes physicality, and that for there to be atoms and molecules and galaxies there must first be consciousness. This is a very broad definition of consciousness which should be saved for more metaphysical discussions.
2. The functions and operating properties of consciousness described here are a simplification of the functions of the human brain, but they are an ample enough description for modeling human consciousness in any environment.
3. This definition of deliberative recall is simplified and based on principles of deductive and inductive reasoning. This definition compresses a much larger discussion on the various types of neural logic and does not account for human emotional irrationality, but it is the minimum definition needed to model the output of human reasoning.
4. The so-called "binding problem" of multisensory perception is approached from a variety of directions, but current theories rely on measuring the strength, frequency, synchrony, and resonance of spike waves propagating through neural assemblies. There are many ways to estimate the relative cooperation between separated brain areas based on their wave properties. Coherence is a term used to indicate strong signal cooperation between separated areas. Areas that are high in coherence may act like coupled oscillators in a feedback circuit, or they may take the form of parallel circuits engaged in a synchronized but distributed processing task.

6. WikiPedia.org, "Control Theory". Internet Reference, 2010.
7. The most compelling examples of mental illnesses which destabilize consciousness are Alzheimer's disease, which affects memory, and schizophrenia, which affects coherence and linear stability. These two examples compress a much larger discussion of how the degradation or loss of specific functions and operating properties of consciousness lead to specific pathologies.
8. Top-down modulation of waking consciousness is a function of aminergic modulation in the forebrain - serotonin and dopamine focusing and maintaining attention - but total homeostatic regulation of brain and body is generally considered to be a function of the hypothalamus. From WikiPedia: "The hypothalamus co-ordinates many hormonal and behavioral circadian rhythms, complex patterns of neuroendocrine outputs, complex homeostatic mechanisms, and many important behaviors."
9. Fasting, chanting, meditation, trance-dancing, isolation tanks, mind machines, and other non-drug visionary practices are rituals designed to destabilize homeostasis through deprivation and hypnotic repetition. Psychedelic drugs achieve more dramatic results by directly interrupting neuromodulatory pathways at the receptor site.

12. See Chapter 06, "Control Interrupt Model of Psychedelic Action".
13. Metaprogramming is the term John Lilly chose in the text, "Programming and Metaprogramming in the Human Biocomputer". Splintering is a term used in brainwashing to describe the process of breaking the subject's identity into multiple pieces through stress exercises, making them vulnerable to imprinting and manipulation.

Chapter 05

Limits of Human Perception

Any discussion of psychedelic hallucination is a discussion of the spontaneous emergence of information in human perception. Human perception is limited by the capacity of sense organs; the speed and architecture of the neural network; and the number of distinct perceptions the brain can analyze at any one time. Despite functional limitations, human consciousness is seamless, meaning that each perception and behavior flows smoothly from one to the next. When consciousness is stable, perception and behavior is seamlessly integrated; when consciousness destabilizes, perception and behavior lose cohesion until we are no longer in control of our thoughts and actions. Destabilization of consciousness can happen all at once, in the case of being knocked unconscious, but more often it happens incrementally, as in going to sleep.

Psychedelics are unique in that they can both enhance and degrade perceptual limitations by orders of degrees; psychedelics can obscure and distort perceptual data, or they can enhance resolution and generate expanded states of consciousness. These contrasting results may be dose dependent, but it is also possible that psychedelics simultaneously produce perceptual degradation and enhancement. Psychedelic hallucinations are often described as being beyond the limits of human imagination, a trait which is offered as de-facto evidence of expanded consciousness or supernatural dominion. Since the boundaries of the human imagination can be modeled with some close degree of accuracy, any substantial discussion about the nature of psychedelic hallucination must therefore start with some basic assumptions about the limitations of human perception, and thus the functional limitations of expanded consciousness.

The Visual Spectrum

The human visual spectrum has evolved to work best in a small window of sunlight penetrating the Earth's atmosphere, comprising the white-light band seen in a rainbow; roughly the 400-790 THz (terahertz) energy range which oscillates on the order of hundreds of trillions of cycles per second. The smallest wavelength of visible light is violet, which is only 380 nm (nanometers) wide and travels with the highest frequency. Red, by contrast, is 750 nm long on the other end of the visible spectrum, and at twice the length it travels at half the frequency.[1] Unlike some organisms, the human eye does not see into ultraviolet or infrared rages, nor does it see microwaves, radio waves, x-rays, gamma rays, or anything that falls out of the visual spectrum. This also applies to night vision and dark-adapted vision. The dark-adapted eye utilizes the rod cells as opposed to the cone cells of daylight vision; rod cells are more photosensitive and more numerous, but they lack the color sensitivity and detail resolution of daylight rendering.[2]

Subjects on psychedelics often report increased luminosity and saturation of colors, as well as halos or auras of light surrounding objects; this implies an increase in color saturation and photosensitivity likely related to dilated pupils associated with 5-HT$_{2A}$ agonism. In closed-eye or low-light environments subjects report vividly saturated geometric matrices rendered in swirling palettes of fluorescent purple and neon green.[3] All of these reports fall within the expected range of an overly saturated visible color spectrum, with the dark-adapted eye finding more sensitivity in the shorter-wavelength, higher-frequency, violet to green ranges.

There is speculation that psychedelic hallucination is the result of tuning the brain to receive cosmic radiation at a wider bandwidth than normal; bands associated with electromagnetic, metaphysical, morphogenetic, Akashic, or geomagnetic fields. This so-called spectral argument posits that instead of producing consciousness, the human brain acts as a radio receiver for consciousness, and psychedelics allow the user to tune the brain to new perceptual frequencies, possibly higher dimensional in nature. This metaphor may make intuitive sense, but no research exists to confirm any spectral advantage to psychedelics other than increased photosensitivity and some visual acuity at low doses.[4,5,6] Subjective reports indicate that psychedelics may increase auditory or synesthetic sensitivity to electromagnetic background noise, and the perception of energy fields or auras emanating from living organisms is reported often enough to warrant further scientific scrutiny, but these claims have not been tested rigorously enough to be conclusive.[7] The spectral argument is further weakened by the observation that if the human eye can be tuned to see a novel frequency range, a mechanical spectrum analyzer should also be able to pick up information on that same frequency. To date no hidden psychedelic spiritual energy fields have been detected by even the most sensitive spectral scanning devices.

Visual Frame Aliasing

Seamless perception relies on rapid frame updating to render external changes in real time. Humans can render changes in reality at roughly 13-15 frames per second (fps, or Hz), which means that human reality fully refreshes roughly once every 77 milliseconds (ms), and open-eye saturation of peripheral filling fully fades at around 10-20 seconds (Fig. 5). Human frame perception is exploited by animation and film, which updates at 24 fps, and television, which updates near 30 fps. Computer monitors and high-definition televisions refresh at 60 Hz or higher, and at this rate human perception of motion is entirely seamless.[8] The rate of human frame perception corresponds roughly to the alert beta range of waking human consciousness (12-30 Hz) seen in EEG readings.[9] Any event which happens faster than 1/60th of a second (16.6 ms) falls between perceptual frames and is considered to be subliminal or imperceptible to human consciousness.[10] Seamless frame rendering is also called temporal aliasing, and can be subverted by a variety of common phenomena, including stroboscopic lights which break motions into jerky snapshots, and wagon-wheel illusions where rotating spokes appear to stop or spin backwards.[11,12,13]

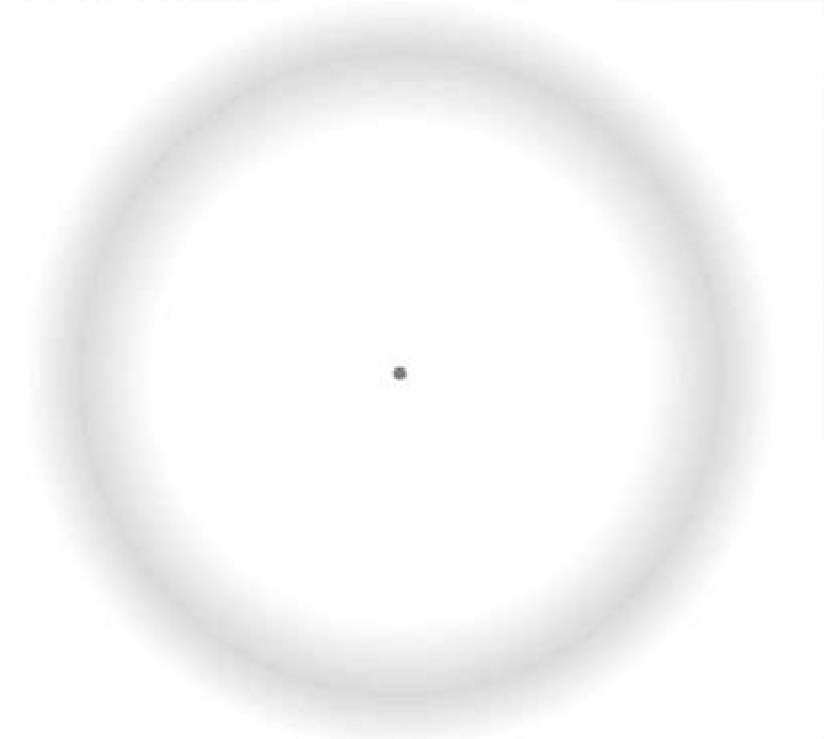

Figure 5. Troxler's fading illusion demonstrates temporal decay of peripheral filling. Stare at the dot in center of image and hold eyes perfectly still for a count of 20. The border around the dot will being to fade. Blinking or moving the eyes will bring the fading areas back. From WikiPedia.

In addition to retaining visual information, perceptual frames hold the totality of multi sensory rendering. Smooth frame aliasing preserves semantic state information from one moment to the next, and retains fidelity of information held in working memory. There is evidence that the brain can track multiple object layers for each frame;[14] possibly corresponding to the number of distinct items we can sustain in working memory, which is about seven.[15] Frame rendering is a distributed cortical task modulated by the aminergic system. High aminergic modulation of the frontal lobe is a good indicator of external frame alertness. Any drug which interrupts the precise timing of the aminergic modulatory system will also disrupt the seamless nature of temporal frame aliasing in the same way that a strobe light disrupts the motion of a spinning wheel. Temporal aliasing hallucinations include frame stacking, frame delay, frame freezing, frame reverse, frame echo, and infinite frame regression; all of which are considered to be uniquely psychedelic.[16] The sensation of hallucinogenic frame stacking indicates that psychedelics may create a temporary frame decay buffer that allows for simultaneous multi-frame analysis and increased complexity of visual comprehension. Subverting or enhancing the limits of visual frame aliasing is an indication of expanded consciousness.

Visual Frame Resolution

Human visual resolution is limited by a number of factors. The first limitation is the density and distribution of retina in the eye; 130 million photoreceptors feeding into 1.2 million optic projections, with a spatial compression ratio of roughly 100 to 1. Photoreceptors in the eye are distributed in rings with color-sensitive cones clustering towards the center and contrast-sensitive rods filling the periphery.[17] Despite the large number of photoreceptors the field of vision is incomplete. Including the blind spot where the retina attaches to the optic nerve, as much as 20% of peripheral vision contains gaps that must be filled with progressive rendering. Incoming rings of visual data must be smoothed into lines and shades in the visual cortex; a process that can produce artifacts of the spatial network when destabilized.[18] The smoothed visual image is then passed forward in two divergent projections for spatial and object analysis, and the finished image reaches multi-modal convergence in the PFC (Fig. 4).[19] This is a fair bit of signal juggling for any processor to handle at 15 frames per second.

Even though human vision employs elaborate compression and reconstruction techniques, the human eye can detect visual detail at resolutions into the micrometer range. From a meter's distance the human eye cannot detect detail under 100 micrometers in length, making print resolutions of 300 dots-per-inch (DPI) entirely seamless. Some estimates put the detail of human visual resolution at 14 million pixels per the entire visual field; or by the 3D topographical field-rendering limit of 10 billion triangles per second, or 760 million triangles per frame.[8] Human detail resolution is only reliable near the center of vision; many optical illusions exploit perceptual filling functions of the periphery (Figs. 5 & 6).[20,21,22] Given the mechanical shortcomings of peripheral rendering, these estimates should be taken as visual saturation points as opposed to functional capacities.

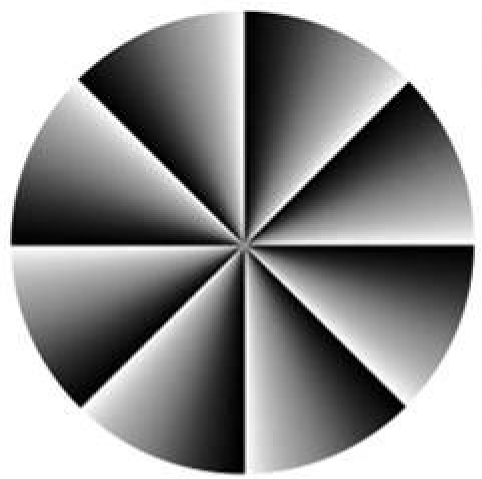

Figure 6. The peripheral drift illusion (PDI) is easily seen when this image is in the visual periphery. Research suggests the illusion is based on temporal differences in tracking luminance along four degrees of gradation. The fourstep gradient processing produces a temporally mismatched contrast signal that fools the peripheral motion system. WikiPedia, Faubert & Herbert, 1998.

Dreaming, Imagination, Psychosis, Hallucination

While the information resolution of imagination and dreams is difficult to measure, it is widely agreed that dream perception is less resolved in detail than waking perception. Dreams are incomplete; contextual state data is not retained from frame to frame; and thus the durability of dream data falls apart under close scrutiny. Sometimes dreams can be vivid to the point of being indistinguishable from reality, containing people and places and narratives that retain state information over many different sequences, but more often dreams are fleeting and half remembered, lasting only a few seconds before fading.

Visual rendering of human imagination is more durable than dreams, but is also very low in resolution. Humans can imagine objects, people, and places in their minds, but human visual imagination is not typically photorealistic. Human memory is more semantic than eidetic, meaning that waking thoughts are mostly verbal, emotional, and only minimally visual. Most humans can imagine basic shapes, outlines, and sensual concepts; a smaller percentage can imagine topographical maps and rotate 3D objects in their mind. Visualizing a simple object like a cube or a pyramid is a cognitive task that requires full concentration; and even at peak visualization the internalized form rarely rises beyond a blurry silhouette. The exception to this limitation is dreaming or daydreaming, when eidetic or photographic snapshots bubble up into consciousness almost fully-formed. The emergence of dreamlike eidetic information into waking consciousness is usually a spontaneous reflex; few people have full control over photorealistic rendering of imagination and memory.[23,24]

Having fully-formed visions spontaneously erupting into consciousness is sometimes called overactive imagination, daydreaming, vivid memory recall, eidetic memory, photographic memory, emergent ideation, hallucination, or psychosis. Each of these modes of internal visualization is characterized by a different intensity and duration of imaginary detail; the more intense and durable the phantom detail, the less it looks like imagination and the more it begins to look like psychosis. Mediating transitions between external alertness and internal visualization is a baseline for perceptual stability; confusing the two would be problematic. The function of internal visualization is activated by the medial temporal lobe and modulated by neurotransmitter acetylcholine; psychedelics presumably activate this function spontaneously by interrupting aminergic alertness of the forebrain.[25] If psychedelic hallucinations capitalize on the brain's capacity to produce vivid dreamlike images, we would expect the detail of a psychedelic frame to match the information profile of a dream frame; low information resolution, fleeting and erratic state data, low formal durability from frame to frame. This means that contextual information such as identity, location, and purpose would also morph and transition many times over the period of a few seconds.

If the quality of a hallucinogenic frame matches the formal quality of a dream frame, one could expect psychedelic visions to be of lower resolution than normal vision; but subjective reports indicate that multiple layers of dreaming and waking consciousness can overlap in a single frame, creating a complex overlay of both real and imagined perceptions. Being unable to separate imagination from reality is the clinical definition of psychosis, but also implies an increase in potential frame information density, which implies expanded consciousness.

The Limits of Expanded Consciousness

If the human imagination is infinite, and if psychedelics can expand the capacity of human imagination, then psychedelics can paradoxically make the infinite even more infinite. This makes sense if you accept that infinity is a linear concept which starts at zero and goes in one direction forever; but if infinity is bent into a series of repeating loops and spirals then it begins to look more like a fractal than a line, and thus more psychedelic. Human perception is linear, but humans live in a nonlinear system. One of the basic limitations of human consciousness in the inability to think exponentially; even with mathematics to assist us, envisioning and predicting exponentially complex systems is a vast conceptual hurdle. Psychedelics destabilize linear perceptions of space and time to produce fractal states of frame layering, bifurcation, and infinite frame recursion. This allows perception to become exponential, to exist in multiple states at once, much like a quantum computer that processes multiple simultaneous probabilities. If normal human imagination is bound within the limits of linear infinity, psychedelic perception is expanded to the limits of exponential or fractal infinity. Psychedelic perception presents a progressive nonlinear bifurcation of recursive self-similar information corresponding to both internal and external perceptual space. The psychedelic layering, bifurcating, and regression of internal and external perceptions creates a timeless, transpersonal perspective of a fractal rendering of time and space.[26]

The perception of seeing all time and space unfolding as a single unified function is a theme that has been reproduced in Eastern mandalas and Mesoamerican calendars for thousands of years, where a central figure sits in the center of concentric interlocking rings of reality (Fig. 7). In Sanskrit this great wheel of time is called Kalachakra (time wheel), and Kalachakra yoga emphasizes the interlocking self-similarity of body cycles and celestial cycles.[27] The description of Kalachakra overlaps with Mesoamerican cyclical calendars and spiritual themes, expressed by María Sabina, the Oaxacan healer who first shared the magic mushroom known as *Teonanacatl* with R. Gordon Wasson. Sabina said, "The more you go inside the world of *Teonanacatl*... you see our past and our future, which are there together as a thing already achieved, already happened... I knew and saw God: an immense clock that ticks, the spheres that go slowly around, and inside the stars, the earth, the entire universe, the day, the night... He who knows to the end the secret of *Teonanacatl* can even see that infinite clockwork."[28] This is undoubtedly a reference to Kalachakra, the great wheel of time.

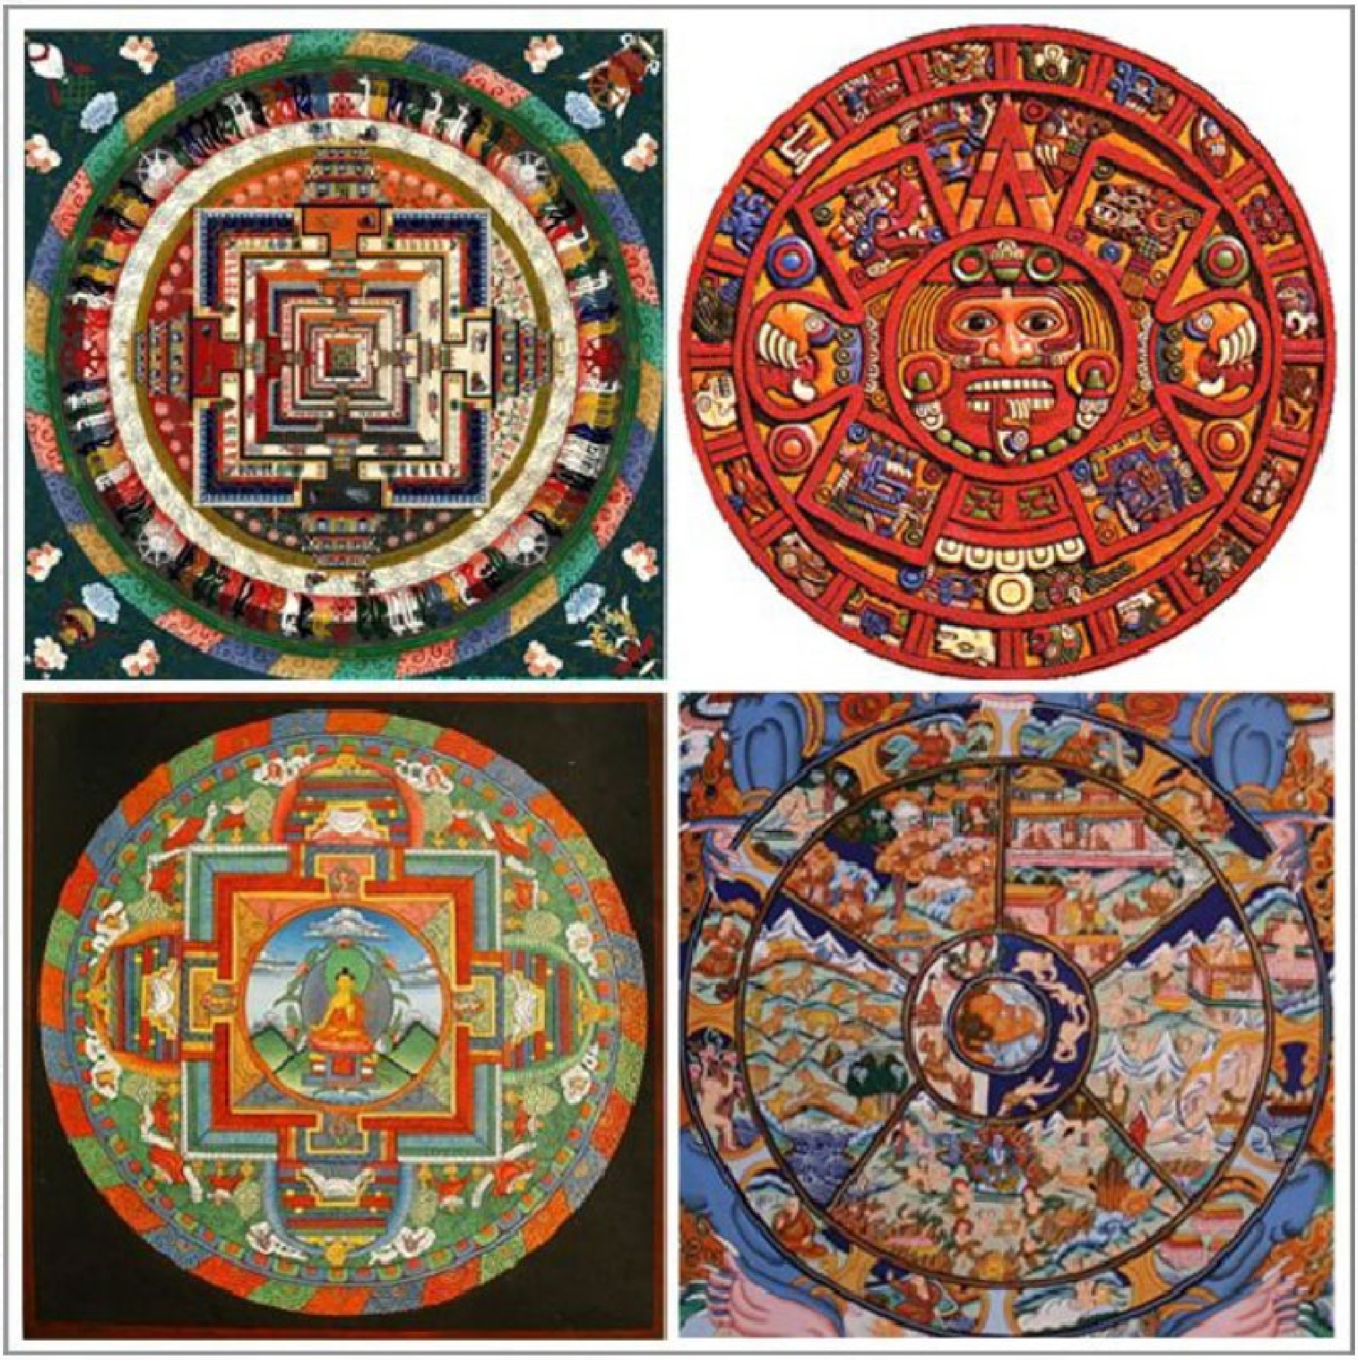

Figure 7. Mandalas and calendars representing universal harmony and knowledge. Top row: a Kalachakra time-wheel mandala; a Mesoamerican calendar. Bottom row: a mandala of the enlightened Buddha; a mandala of the Wheel of Life (Bhavacakra, or samsara). Nonlinear art embeds holographic information - such as an entire cosmology - into a single image.

Witnessing the timeless infinity of Kalachakra can be compared to Western models of Gnosticism and Hermeticism ("As Above, So Below") where the pinnacle of mystical achievement is channeling the infinite wisdom of the universal spirit;[29] or early Deist notions of a God as a great Clockmaker who set the universe in motion and let it run without intervention.[30] According to María Sabina's report, the subjective experience of the infinite clockwork is an end secret of psychedelic vision; this is where you arrive if you follow the process of fractal information regression to the beginning and end of all time. The thought of experiencing Kalachakra as expressed by María Sabina stretches the boundaries of believability, but the subjective reports of a timeless, infinite psychedelic space where the size of the universe is revealed and everything in the past and the future has already occurred is common enough to conclude that this experience is not only possible, but that it might be the end-point of expanded human consciousness.[31]

31. Exploring the mystical implications of Kalachakra, the great fractal time wheel, has filled many volumes and fueled many prophecies. There is a solid case to be made that Kalachakra is the pinnacle of all mystical achievement; the end of psychedelic exploration; and the endpoint of human consciousness. Since the psychedelic Godhead is a transcendent state of timeless, infinite, omniscient consciousness, it is doubtful that anything more complex or expansive can ever be experienced by the human mind, marking the functional end-point of expanded consciousness.

Chapter 06

The Control Interrupt Model of Psychedelic Action

The brain is an information processing organ that uses top-down signal modulation to control the flow of bottom-up sensory input. Feedback modulation of incoming signal is an example of self-stabilizing control in an information processing system. Using the tenets of cognition and control theory it is possible to describe a model in which hallucinogens periodically interrupt the top-down modulatory control of perception to create sensory interference patterns, multisensory frame destabilization, and altered states of consciousness.

Bottom-up Perception, Top-Down Control

What we perceive as waking consciousness is a synthesis of bottom-up sensation modified by top-down expectation and analysis.[1] Incoming sensation is gated by the top-down focus of subjective attention. Inhibitory feedback subtracts background noise while excitatory feedback resolves and amplifies salient data. This configuration describes a signal filter-amplifier with an inhibitory-excitatory feedback loop to control signal focus and content discrimination. The top-down filtering and focusing of sensory signal is an autonomic reflex and is perceptually seamless; the brain blocks background noise, transitions focus, and recognizes objects without disrupting subjective frame continuity. Without the ability to control incoming sensory signal with feedback, perception would become under-constrained, distracted, overloaded, exuberant, and error-prone. Under-constrained internal sensory noise entering into multisensory awareness would be perceived as hallucination.

Constraint, Control, and Feedback Inhibition

Feedback excitation is applied in sensory circuits to amplify salient input, but the majority of the brain's feedback circuits are inhibitory, meaning that human consciousness is more constrained than unconstrained. In dynamical information processing systems, signal constraint and error correction is applied through negative feedback to subtract or cancel perturbation and noise entering the signal circuit; this is known as control theory. In sensory networks, such as the layers of the cortex or the retina, fast inhibition is applied laterally to boost contrast discrimination in line detail; this is called lateral inhibition. Fast inhibition in the cortex can also be applied from the bottom-up as well as laterally, this is called the synaptic triad of fast inhibition. Inhibition can also be applied from the top-down, allowing the logical cortex to filter or ignore noisy input from the thalamus; this is called top-down feedback inhibition, and it is typically tonic, meaning top-down feedback is inhibitory over many consecutive spike trains to control extended periods of channeled focus. When the brain is alert and focused, this means it is highly constrained by inhibitory feedback.

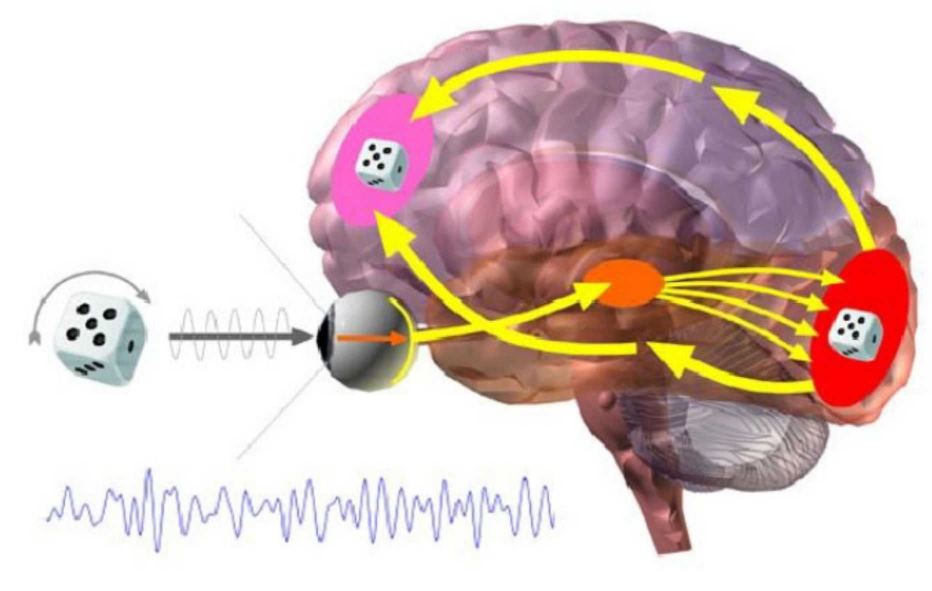
When people express their fears about psychedelics, the most commonly voiced concern is the fear of losing control. Common entheogenic wisdom states that you must relinquish control and submit to the experience to get the most out of psychedelics. Holding onto control causes negative experiences and amplifies anxiety. Metaphors for control and submission are applied to psychedelics because hallucinogens subvert various forms of feedback control, allowing perception and behavior to become unconstrained and unpredictable. Extreme states of under-constrained perception would include sensory saturation, sensory echo, synesthesia, hallucination, disorientation, and confusion. Extreme states of under-constrained behavior would include mania, hysteria, paranoia, euphoria, and as the system becomes totally overloaded, catatonia.

Loss of feedback restraint in a dynamical information processing system causes output to become exuberant and unpredictable; this is called deterministic chaos, or chaos in deterministic systems. In order for a perceptual system to transition from a linear to a chaotic or nonlinear state, negative feedback control must be removed or subverted by a periodic driving force. If control is entirely removed then perception becomes totally unconstrained, leaving a system that is quickly overloaded with too much information. If control is placed in a partially removed state, or in a toggled superposition where it is alternately in control and not in control over the period of a rapid oscillation, then the constraints of linear sensory throughput will bifurcate into a nonlinear spectrum of multi-stable output with signal complexity correlating to the method of control interruption.

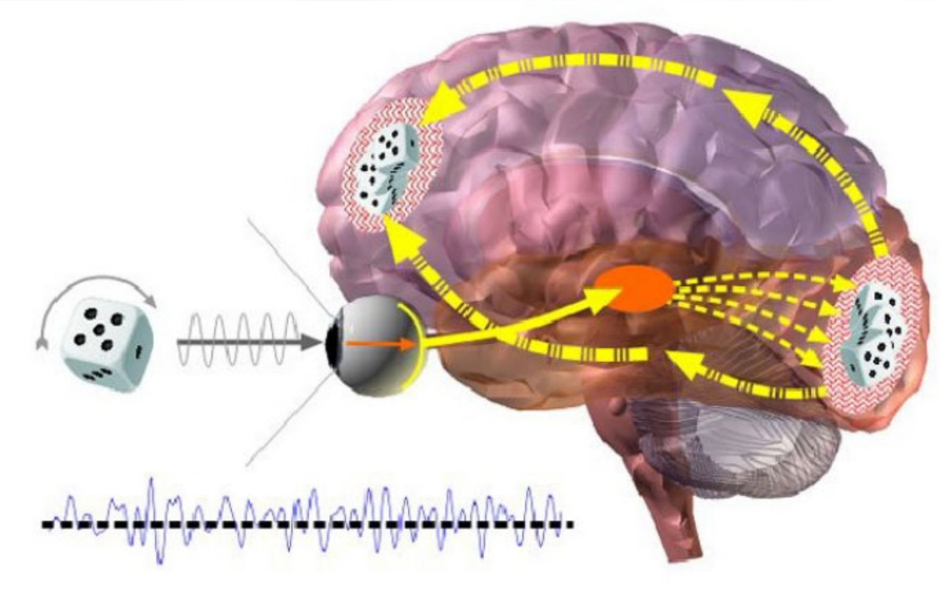
The Control Interrupt Model of Psychedelic Action

Before the mind can start hallucinating, the top-down modulatory control of consciousness must first be interrupted. Interrupting top-down control of consciousness allows the mind to destabilize into novel information processing configurations. When top-down control of waking consciousness is destabilized, neural oscillators in the brain will spontaneously organize into coherence with the most energetic local drivers. This process can be described in terms of oscillator entrainment and resonance; when the modulatory driver maintaining global oscillator coherence is interrupted, uncoupled oscillators will naturally fall into synchrony with most energetic periodic drivers in the environment.[2] In this state, the normally inflexible configurations of consciousness and perception become extensible and open to the influence of environmental feedback. This explains why psychedelics create synesthesia or cross-sensory representations of energetic sensory drivers, and why set and setting have a profound influence on the tone and content of a psychedelic experience.

Figure 8. Stabilized and Destabilized Perception.



Stable perception refreshes at 15 frames per second, allowing seamless update of consciousness in the beta range of 12-30 Hz, indicated by the wave. At this refresh rate objects and textures can be rendered with high precision.



When the precise frame refresh rate of perception is interrupted, consciousness destabilizes and begins to track overlapping information from multiple receding frames. Destabilization, feedback, and latency of frame refresh creates sensory echo and complex frame interference patterns.

When top-down modulatory control of consciousness is interrupted, the seamless nature of multisensory perception degrades and the subject begins to experience hallucinations (Fig. 8). Early indicators of modulatory interruption include periodic high-frequency distortion or noise in sensory networks. In tactile networks this periodic interruption may be felt as parasthesia, or phantom tingling and pulsating; in visual networks it may be perceived as phosphenes, or strobing or flickering of light intensity, possibly fast enough to produce geometric hallucinations; in audio networks it may be perceived as tinnitus, ringing, humming, buzzing, or tones that cycle up and down in pitch. These are all descriptions of field-based hallucinations generated in response to periodic interruptions along multisensory signal pathways. The speed and intensity of the control interrupt, and thus the speed and intensity of the hallucinations, are a direct result of the hallucinogen's pharmacodynamics and method of ingestion.

Control Interrupt Envelopes

Using control interruption as the source of hallucinogenesis, we can model hallucinogenic frame distortion of multisensory perception the same way we model sound waves produced by synthesizers; by plotting the attack, decay, sustain, and release (ADSR envelope) of the interruption as it effects consciousness (Fig. 9).[3,4] For example, nitrous oxide (N_2O) inhalation alters consciousness in such a way that all perceptual frames arise and fall with a predictable "wah-wah-wah" time signature. The throbbing "wah-wah-wah" of the N_2O experience is a stable standing wave formation that begins when the molecule hits the neural network and ends when it is metabolized, but for the duration of N_2O action the "wah-wah-wah" completely penetrates all modes of sensory awareness with a strobe-like intensity. The N_2O sensation is often described as a soft tingling, throbbing, or buzzing that grows to consume all sensation.

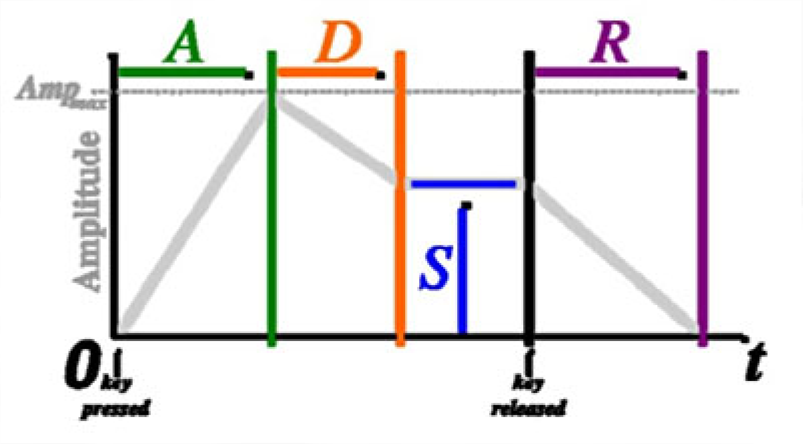


Figure 9. Using an Attack-Decay-Sustain-Release (ADSR) envelope we can model the intensity of hallucinogenic interrupt for any drug. From WikiPedia.

Taking into account the subjective reports of N_2O action, the periodic interrupt of N_2O's "wah-wah-wah" can be modeled as a perceptual wave ambiguity that toggles back and forth between saturated consciousness and semi-consciousness at roughly 8 to 11 frames-per-second, or @8-11 Hz (hertz).[5] Consciousness rises at the peak of each "wah" and diminishes in the valleys in between, growing in sustained intensity with each cycle until the subject passes out. On subanesthetic doses, N_2O creates a looping effect where frame content overlaps into the following frame, causing a perceptual cascade similar to fractal regression. We can thus model the interrupt envelope of N_2O as having a rounded attack, fast decay, low sustain, medium release, with an interrupt frequency of @8-11 Hz. Any psychoactive substance with a similar frequency and shape of interrupt envelope will produce results that feel similar to the N_2O experience (Fig. 10). For instance, smoked *Salvia divinorum* (vaporized Salvinorin A&B, or Salvia) has an interrupt envelope similar to N_2O, except Salvia has a slightly faster interrupt frequency (@12-15 Hz), a harder attack, a slightly longer decay, a more intense sustain, and a slightly longer release.[6] These slight changes in the frequency and shape of interrupt envelope cause Salvia to feel more physically intense, more hallucinatory, and more disorienting than N_2O, even though they share a similar throbbing or tingling sensation along the same pathways and frequency range.

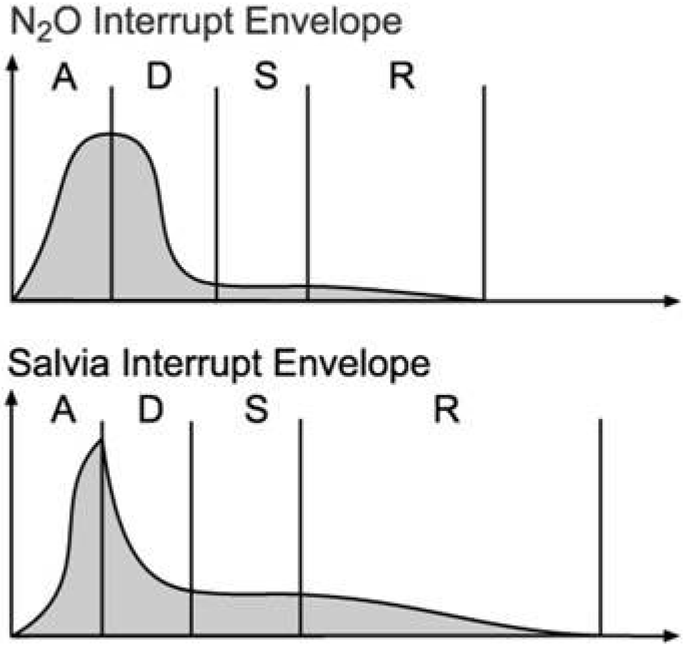

Figure 10. Modeling the interrupt envelope for N_2O and Salvia we can see N_2O has a hard but rounded attack and decay. In contrast Salvia has a slightly faster and more intense ADSR profile, describing a slightly more biting and disorienting effect on multisensory perception.

Using interrupt envelopes we can contrast smoked Salvia or inhaled N_2O with vaporized DMT (*N,N*-dimethyltryptamine), which when smoked has similar onset and duration to both substances but very different hallucinogenic effects. Unlike the slow throbbing periodicity of N_2O or Salvia, vaporized DMT produces an interrupt frequency associated with a high-pitched carrier wave and high-speed frame flicker (24-30+ Hz). The frequency of DMT's interrupt is so rapid the entire body ramps up in panicked response to the new driver. The rate of DMT's visual frame flicker is fast enough to instantly produce geometric hallucinations and fully realized animations.[7] Taking these subjective effects into account we can model DMT's interrupt envelope as having a moderate attack, long decay, medium sustain, long release, and high frequency (24-30+ Hz). The moderate attack means DMT's perceptual frame interference is less of a physical throbbing than N_2O, but because of a higher frequency and longer frame release the rendering of DMT hallucination is more fluid, detailed, seamlessly aliased, and fades longer over a higher number of frames.

The interrupt envelopes modeled here are approximate and based on reported subjective effects, but may also give some insight into the pharmacodynamics of each substance.[8] Following the logic of the Control Interrupt Model, it can be assumed that each hallucinogen has a unique interrupt envelope based on receptor affinity, receptor density, rate of metabolism, and so on, and each unique interrupt envelope creates a distinct type of interference pattern in multisensory perception. The interrupt envelope for any substance will also change if the substance is ingested orally as opposed to vaporized or injected; the speed of absorption into the bloodstream will naturally affect the intensity of ADSR values. This is why each psychedelic can produce unique sensations and hallucinations, and why each psychedelic can produce subtle variations in the speed and intensity of hallucination depending on method of ingestion.[9]

By modeling the interrupt envelope of a psychoactive substance it is possible to accurately predict its subjective results on multisensory perception. Non-drug sources of hallucination, such as those caused by psychosis, deprivation, fever, or schizophrenia, may also have unique and quantifiable control interrupt envelopes related to erratic multisensory frame modulation.

Control Interrupt and Shamanism

If consciousness must have a top-down control frequency to remain stable, and psychedelics produce a periodic interruption of this control frequency, then the interaction between the perceptual control frequency and the periodic interruption can be described as a wave interference pattern in global oscillator coherence. Subjects on moderate doses of psychedelics can override the hallucinogenic interrupt and retain global coherence via energetic physical movement or repetitive behaviors like chanting or dancing. Conversely, if the subject lies motionless, then the interruption fully destabilizes alert consciousness into a depersonalized dreamlike trance.[10] These reports indicate that even though psychedelics destabilize top-down modulatory control of consciousness, feedback control and linear system stability can be entrained back into coherence via external periodic drivers, including rhythmic motor activity, drumming, singing, chanting, rocking back and forth, dancing, and so on. It is no accident that these are also the basic formal elements of shamanic ritual.

In physical terms, the shaman is the primary energetic driver, or resonator, stabilizing attractors within the chaotic hallucinogenic interference pattern created in the consciousness of the subject. In the mathematics of nonlinear dynamics, this phase-locking action is similar to deterministic chaos seen when entraining limit cycles in a forced Van der Pol oscillator.[11] By prescribing a psychedelic substance, the shaman introduces the control frequency interrupt, and through ritual craft and showmanship the shaman applies harmonic interference to navigate and influence the tone and texture of the trip. By mixing the hallucinogenic control interrupt with a harmonic periodic driver the shaman can entrain expanded states of consciousness and manipulate the subject's mind with high precision. The precision wave-based manipulation of neural oscillators within the psychedelic state can be called applied psychedelic science, physical shamanism, or Shamanism in the Age of Reason.

5. N_2O interrupt envelope is an approximation based on subjective reports.
6. Salvia interrupt envelope is an approximation based on subjective reports.
7. DMT interrupt envelope is an approximation based on subjective reports.
8. Most receptor interactions occur on the order of microseconds, so attempting to model pharmacodynamics based on rate of subjective frame interruption may be impossible, or require complex statistical interpretations.
9. ADSR envelopes will change slightly for any substance depending on dose and speed of absorption into the bloodstream, but beyond that they may also change depending on the purity of hallucinogen. For instance, if an LSD experience is described as "clean", this means the hallucinogenic interrupt is so subtle that it is almost invisible; this also implies purity of the LSD. In contrast, when an LSD experience is described as "dirty" or "jagged", this means the interrupt induces transitions in consciousness that are abrupt and unpleasant; this also implies the LSD is adulterated or has not been sufficiently purified. It is widely accepted that if one batch of LSD induces a soft interrupt envelope with a wiggly and sensual attack, that same LSD should produce similar result for everyone. The same would be true for LSD that produces a jagged and abrupt attack. If a pure sample set could be acquired and tested, it may be possible to model precise interrupt frequencies and ADSR envelopes for every known psychoactive substance.

Chapter 07

Psychedelic Pharmacology

Sensory signal traveling through the brain is mediated by glutamate, an excitatory chemical messenger. Sensory signal is filtered by GABA, an inhibitory messenger GABA (Fig. 11).

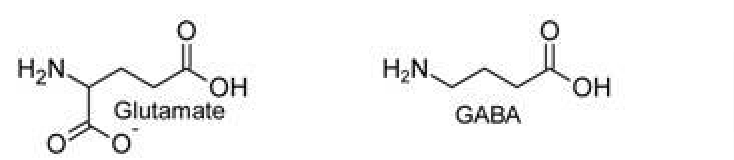

Figure 11. Glutamate and GABA, the neural messengers for go and stop. Glutamate excites neurons and promotes spiking, GABA inhibits spike trains.

The precise spike timing of these messengers is tuned by neuromodulators, which synchronize spiking across the entire brain. Most hallucinogens are structurally similar to the modulators which tune global spike timing, such as serotonin (5-HT), norepinephrine (noradrenaline), and dopamine (DA) (Fig. 12). All of these chemicals are classified as amines, meaning that they have a nitrogen (N^+) containing amino group hanging off a root carbon ring. This nitrogen structure is the key element in any amino acid, carrying the energy needed for metabolic processes which do work. Since these transmitter chemicals have only one nitrogen group they are called monoamines, and they are the essential messengers of the aminergic neuromodulatory system.

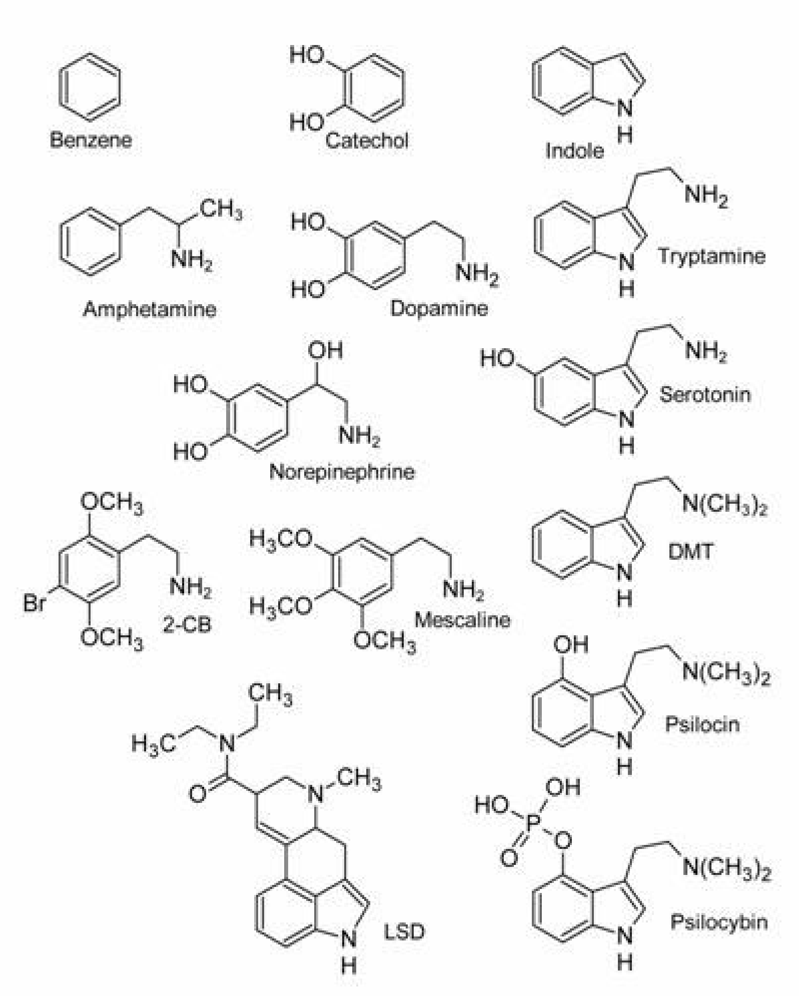

Figure 12. Psychedelic amines look very much like the endogenous neurotransmitters serotonin, norepinephrine, and dopamine. On the left are the adrenal-promoting catecholamines, amphetamines, and phenethylamines; on the right are the indoleamines, also called tryptamines, and their hallucinogenic counterparts. LSD, a synthesized molecule, is also an indoleamine, but is more structurally engineered than its organic counterparts.

Monoamines entering the bloodstream are normally kept out of the brain by the blood-brain-barrier, but psychedelic molecules have a neutral charge so they are able to pass. When these amine crystals pass through the blood-brain barrier they brush against neural receptor sites; if the receptors are a good fit then the crystals get stuck for a short period of time. The bonding of amine ligands to serotonin and dopamine receptors is where psychedelic action begins.[1,2]

Serotonin and the Tryptamines

Because of depressive mood disorders and pharmaceuticals like Prozac, the most well known neuromodulator is serotonin, or 5-HT (5-hydroxytryptamine). 5-HT is essential to many basic brain functions, linked to mood, depression, contentment, learning, anxiety, sleep, appetite, and the regulation of involuntary smooth muscles that control blood pressure and digestion. Serotonin is an indoleamine and a variant of tryptamine, which is the most basic of all the indoleamines and the structural starting point for DMT (*N,N*-dimethyltryptamine), 5-MeO-DMT, psilocin, psilocybin, DPT, AMT, and most psychedelic drugs with acronyms ending in T (which stands for Tryptamine). LSD is also an indoleamine, but it is larger and more complex than organic indoleamines, and is in many ways structurally unique.

Dopamine and the Phenethylamines

Working in concert with serotonin is the neuromodulator dopamine (3-hydroxytyramine). Dopamine is synthesized from L-DOPA and is instrumental in modulating salient attention, motivational response, and fine motor control. Dopamine is central to the reward system, and dopamine release is stimulated by recreational drugs, food, gambling, sex, and physical risk taking. Dopamine imbalances are linked Parkinson's disease, ADD, compulsive risk behavior, and psychosis. The role of dopamine interruption is relevant to psychedelic activity in many aspects; psychedelics may affect sensuality and motor control, and may facilitate psychosis, mania, and compulsive behaviors.

Amphetamines and the phenethylamine group of psychedelics (mescaline, 2-CB, MDA, MDMA, and so on) are more structurally similar to dopamine, epinephrine, and norepinephrine, which are also monoamines but sometimes referred to as catecholamines since they are based on the single catechol ring structure. Epinephrine and norepinephrine are referred to as stress hormones because they prime the body's adrenal production and energy response to stress and danger. The phenethylamines and catecholamines all have the six-carbon benzene ring backbone, simpler than the dual-ring tryptamine structure, with at least one amine group. The simplest form of this molecule is called phenethylamine, and is similar to amphetamine.

In very general terms, the phenethylamine psychedelics are said to be more energetic, sensual, empathogenic, or entactogenic, while tryptamine psychedelics are thought to be more hallucinogenic, disorienting, and somatically heavy. These descriptions are very broad, but this is the popular distinction made between the two major classes of psychedelics.

Neuromodulators and Global Brain States

Serotonin, dopamine, and the other monoamines don't cause neurons to fire, they instead tune the spiking rate of neurons, which means they adjust global network polarity over time to make neural assemblies more or less responsive to stimulus. Serotonin and dopamine are projected into higher areas of the brain from nuclei in the brainstem and middle brain, meaning they are primal signaling mechanisms for modulating many areas of the brain simultaneously. The axons from these aminergic clusters reach upward to many areas of the cortex, affecting the thalamus (sensory filter), amygdala (fear and survival), hypothalamus (homeostatic regulator), hippocampus (memory and learning), and neocortex (sensory and logic processing). Neuromodulators synchronize the neural response to incoming stimulus and keep local competing brain circuits functioning smoothly and in unison. These neuromodulators produce a one-way bottom-up effect, which means they are switched on and off reflexively and unconsciously by glands in the brainstem and basal forebrain in direct response to internal conditions or external stimulus. With neuromodulators the brainstem can exert global homeostatic control over organism mood and behavior. The effect of the aminergic modulators projected upward by the brainstem are tonic, which means their signaling effects are sticky and persist over the duration of many incoming spike trains.

Generally serotonin is thought to have a polarizing effect on neurons, making them less likely to fire and thus having an overall relaxing effect on the brain. This is why many depression and anxiety remedies focus on increasing the supply of serotonin; to decrease anxiety and increase satisfaction. If we assume psychedelics are mimics for neurotransmitters and apply this analogy to DMT, we would expect DMT to have a calming effect on the brain because it looks similar to serotonin. But a flood of DMT does not calm the brain, it makes it hallucinate. Since DMT binds to the same receptor sites as serotonin but does not produce a relaxing effect, it would be logical to assume that DMT is a 5-HT antagonist, meaning it blocks serotonin and depolarizes neurons, making them more excitable. This is not the case. There are many different types of 5-HT receptors, some inhibit neural activity and some promote neural activity. Like most hallucinogens, DMT is classified as a selective 5-HT$_{2A}$ partial or full agonist; also active at other 5-HT subtypes, at DA receptors, at adrenal receptors, at Sigma-1 receptors, and at tertiary amine receptors. This means that DMT is active at many receptor sites and can mimic the agonistic functions of serotonin with varying affinity and efficacy.

5-HT$_{2A}$ partial agonism can be described as a subtle form of aminergic modulatory signal interference. In the most general case it can be assumed that psychedelic activity is due to interference at 5-HT receptor subtypes. In more specific cases we can assume that visual hallucinogenic effect is associated with 5-HT$_{2A}$ and 5-HT$_{2C}$ receptor interaction. Somatic heaviness and dreaminess is associated with broader aminergic interaction; and more sensual, entactogenic, or compulsive effects are associated with dopamine and adrenergic receptor interaction. Psychedelics can have a wide affinity and interact as partial or full agonists at multiple receptor subtypes to produce a wide range of effects.

Because psychedelics are full or partial agonists acting on the same modulatory pathways as 5-HT, the synergistic interaction between these competing agonists can be described in terms of a modulatory wave interference pattern. Agonistic interference at 5-HT subtypes promotes disinhibition and cross-excitability between feedback-coupled assemblies in the brain. Excitation and loss of feedback inhibition in the circuits responsible for processing sensation and perception lead to spontaneous self-sustaining feedback hallucinations. Prolonged states of feedback excitation between the circuits which process perception and memory leads to infinite working memory regression and expanded states of psychedelic consciousness.

Molecular Shape, Receptor Affinity, MAO Metabolism

The strength and duration of the bond a ligand forms with a receptor is referred to as receptor affinity or potency, and is described in terms of pharmacodynamics. The higher the affinity, the stronger and longer the ligand bonds with a receptor, thus influencing neural activity. Research has shown that 5-HT$_{2A}$ receptor affinity is an accurate measure of the potency of any psychedelic compound; the higher the affinity the higher the potency and psychedelic effect.[4,5] Another thing we know is that the conformational shape of the amine determines how long the molecule takes to metabolize and how sticky it will be at 5-HT receptor types.[6] For instance, the amine tail of LSD is different from other tryptamines; it is long, complex, and connects back to the benzene ring, keeping it rigid instead of flexible like most amino groups or substitutions. Designer amines with a similarly rigid molecular structure have also shown a marked increase in psychedelic potency.[7]

Using this information it can be assumed that the unique structure of LSD is what makes it so potent; giving it a high affinity across a wider range of receptor types; making it more difficult to metabolize; and giving it a broader range of effect over a longer duration. DMT also binds to a wide variety of 5-HT receptor types, but it is smaller and metabolizes very quickly. When DMT is taken with a monoamineoxidase inhibitor (MAOi) in an ayahuasca mixture, the enzymes which metabolize DMT are blocked, making the hallucinogenic effects of DMT orally active and longer lasting. Adding an MAOi to any tryptamine psychedelic will make it nearly twice as hallucinogenic.[8] These few pieces of pharmacology tell us that the efficacy of modulatory interruption, or psychedelic potency, can be somewhat predicted by molecular shape, the rigidity of the molecular structure, and speed of metabolic pathways. If metabolic pathways are degraded by synergistic dosing, as in an ayahuasca mixture, then the potency of the drug increases over the duration of effect in direct proportion to the latency of metabolism.

Breadth of Psychedelic Receptor Binding

Table 1 lists the binding strength of popular psychedelic drugs at many 5-HT receptor sites, listed in order of 5-HT_{2A} affinity.[3] This table should be an accurate representation of hallucinogenic potency of various psychedelics in descending order. From subjective reports all substances at the top of this list are very hallucinogenic, but DMT, which is often considered to be the most hallucinogenic, actually falls somewhere in the middle. If we also look at 5-HT_{2C} affinity, which is implicated in hallucination, we can see that all substances at the top of the list also have high 5-HT_{2C} affinity, with DMT and DOI having slightly higher affinity than the rest. 5-HT_7 receptor affinity, which stimulates cAMP activity and the reward system, also seems to be implicated in overall transcendent psychedelic action, with the mystically popular DMT, 5-MeO-DMT, and LSD topping the affinity list for these receptors.

Table 1: Popular psychedelic drug affinities across aminergic receptor targets listed in order of 5-HT_{2A} receptor affinity, with dopamine (D1) and adrenal receptors on the right. A value of 4.00 indicates high affinity at that target; any value under 2.00 should be considered imperceptible. Three non-psychedelic control molecules are listed at the bottom for comparison. From Ray, 2010.[3]

In contrast, there are four non-visual psychedelics at the bottom of the list, 5-MeO-DMT, DiPT, Mescaline, and MDMA. These substances have very poor 5-$HT_{2A,2C}$ affinity, but all have a high 5-HT_{2B} and adrenal affinity; this indicates they are effective at stimulating serotonin production, cardiovascular activity, and acute sensuality. 5-HT_{2B} affinity is quite high for all samples in this list with the exception of DMT and 5-MeO-DMT, making 5-HT_{2B} affinity a good indicator for purely sensual or entactogenic effect. It is interesting to note that DiPT, Mescaline, and 5-MeO-DMT all have a high 5-HT_{1A} affinity, which is generally thought to work in contrast to 5-HT_{2A} agonism to promote well-being and satisfaction. DiPT is unusual because it produces distinct audio hallucinations and little or no visual hallucinations, and predictably does not bond with 5-$HT_{2A,2C}$ receptors implicated in visual hallucination. By analyzing this affinity table it seems possible to predict the relative potency and effect of any hallucinogen based solely on binding profiles, though the three control molecules at the bottom of the list (6-F-DMT, Lisuride, 4C-T-2) are reportedly non-hallucinogenic despite high 5-HT receptor promiscuity; this is likely because they are not active as agonists, they are antagonists, or their binding profiles are not synergistic and somehow cancel each other out.

Dissociatives, Anticholinergics, Other Hallucinogens

Psychedelic tryptamines and phenethylamines are not the only hallucinogens, but all hallucinogens work by interrupting sensory processing pathways. Hallucinogenic dissociatives like ketamine (special K), phencyclidine (PCP), and dextromethorphan (DXM) block NMDA glutamate sensory signaling pathways; these pathways mediate fast sensory signal projection through the brain. Anticholinergic deliriants like scopolamine and atropine interrupt cholinergic modulation of memory, recall, and dreaming; these pathways mediate the smooth input and output of memory from the hippocampus. *Salvia divinorum* interrupts kappa-Opioid tactile sensory pathways; these pathways mediate pain, gravity awareness, and sensation for determining physical orientation in space. Depressants like GHB and alcohol activate inhibitory GABA pathways, pathways which dampen and slow smooth sensory throughput. Nitrous Oxide (N_2O) is the simplest and perhaps the most promiscuous of all hallucinogens, worming its way in between a number of rudimentary signaling pathways to produce anesthetic tingling, dissociation, and out-of-body emergence. Although the pharmacological targets of hallucinogens may differ, in all cases perceptual distortion is linked directly to interruption of seamless multisensory signaling and representation across the cortex. Any drug which interrupts pathways of multisensory signaling or binding will be considered psychedelic or hallucinogenic at high enough doses, which is why so many different types of plants and chemicals can be uniquely hallucinogenic across many different receptor targets.

8. Subjective reports of taking an MAO inhibitor with psychedelic tryptamines such as DMT, psilocybin, LSD, and 5-MeO-DMT confirm that the addition of an MAOi increases potency and hallucination by an order of magnitude. MAOi potentiation can come from plant sources, such as the harmala alkaloids found in *Peganum harmala* seeds and *Banisteriopsis caapi* vine, but is particularly intense with a pharmaceutical source like moclobemide.

Chapter 08

5-HT_{2A} Agonism and Multisensory Binding

Most visual hallucinogens are active as full or partial agonists at the 5-HT_{2A} receptor subtype, and all produce similar visual hallucinations that are immediately recognizable as psychedelic.[1] Although the 5-HT_{2A} receptor subtype is not the only receptor implicated in hallucinogenesis,[2] it is one of the most studied hallucinogenic targets and offers some insights into the nature of psychedelic action. 5-HT_{2A} receptors are ubiquitous throughout the nervous system, found in the sensory cortex, the frontal cortex, the olfactory cortex, the basal ganglia, the cerebellum, the hippocampus, thalamic nuclei, brainstem nuclei, sensory neurons, platelets, fibroblasts, intestines, smooth muscles, and cardiovascular systems.[3,4,5,6] By following the pathways of 5-HT_{2A} modulated signal transduction through the human organism it is possible to extrapolate that psychedelic experience is not limited to mere hallucination, but is instead a complex multi-layered experience integrated throughout all biological signaling systems.

Figure 13. Layers of the neocortex. Sensory signal rises from the thalamus through intermediary cortical layers to the dendritic arbors at the top layer, the very outer membrane of the cortex, where the highest density of 5-HT_{2A} receptors are expressed. The dendrite arbors in layer I connect back down to the large layer V pyramidal cells, which bind multisensory data via lateral projections, recurrent ascending projections, and reciprocal thalamocortical feedback loops. From Grey's Anatomy, modified.

The layering of cellular signaling systems mediated by 5-HT provides a framework for viewing the 5-HT_{2A} pathway as a primary modulator for homeostatic regulation of multisensory awareness, behavior, and learning.[7] 5-HT_{2A} receptor agonists, also known as hallucinogens, promote disinhibition and excitability in 5-HT mediated pathways, indicating that psychedelic action is the product of spontaneous excitation and self-sustaining feedback in 5-HT mediated signaling pathways. The most obvious effects of 5-HT_{2A} agonism are real-time perceptual distortions, or hallucination, but given the wide distribution of these receptors, there are also bound to be more subtle holistic effects on respiration, metabolism, cellular activity, memory, learning, and long term behavior.

5-HT_{2A} receptor mechanics

The 5-HT_{2A} receptor is a G protein-coupled receptor (GPCR), which means it does not activate ion channels or directly alter cell polarity, but instead sets off a chain reaction of intracellular signaling systems involving phosphatidylinositol (PI) hydrolysis, the production of inositol trisphosphate (IP_3), the release of calcium (Ca^{2+}), and the activation of protein kinase C (PKC) as well as various mitogen-activated protein kinases (MAPK).[6,8,9,25] PKC regulates a variety of cellular functions at the membrane, including signal transduction, receptor desensitization, and synaptic formation and strengthening responsible for learning and memory.[10] MAPK regulates fundamental intracellular functions in the cytoplasm and nucleus such as gene expression, proliferation, cell growth, and survival.[26] It is interesting to note that Salvinorin A, another potent hallucinogen, also stimulates PKC and MAPK signaling pathways via kappa-Opioid receptors.[28,29,30] These receptor-mediated secondary pathways undoubtedly play a role in psychedelic neuroplasticity and cellular regeneration,[27] but the stimulation of secondary messengers is not always necessary for hallucination and psychedelic effect.

Layer V pyramidal cells and perceptual binding

In the human brain the highest density of 5-HT_{2A} receptors are expressed on the dendrites of cortical layer V pyramidal cells,[3,4,5,6,8] and the highest density of layer V dendrites project upward into the dendrite arbors of cortical layer I, the very outward surface of the brain (Fig. 13). 5-HT_{2A} receptors in the dendritic arbors of pyramid cells are primarily responsible for modulating asynchronous (late) glutamate release in the wake of strong incoming spike trains,[1,11,12] presumably for enhanced top-down aliasing, latent reconstruction, and memory imprinting of salient sensory data.[13] Sensory signal rising to the dendrites of the cortical surface encodes a highly detailed reconstruction of external perception for latent real-time analysis and progressive perceptual filling. Multiple layers of the neocortex have descending columnar dendrites or ascending recurrent axon collaterals to provide real-time sensory feedback to latent apical rendering layers, allowing a seamless representation of perceptual motion to be synchronized across the cortex. Cortical layer V neurons receiving input through apical dendrites are one of the primary conduits for binding coherent sensory perception across the entire cortical surface.[14]

Layer V pyramidal cells are unique in that they mediate multiple pathways of perceptual feedback analysis.[14,15] For example, in the visual cortex layer V pyramidal cells are responsible for synchronizing corticothalamic activity with the thalamus via descending axons; they mediate feedback discrimination in columnar circuits via recurrent collaterals ascending through Layers I-IV; they mediate reciprocal interareal connections via laterally branching arboreal and basilar dendrites; and they mediate afferent cortico-cortical signal flow to the pre-frontal cortex (PFC) along both dorsal and ventral processing streams. Through lateral, vertical, elliptical, and recurrent feedback connections, layer V pyramidal cells bind multisensory frame data across the cortex with a functional refresh rate of roughly 15 to 30 frames-per-second (FPS), which means these neurons must process and neutralize incoming sensory spike trains at roughly every 30-60 milliseconds.[16] Loss of precise synchrony and coupling in these circuits would necessarily lead to loss of temporal fidelity in multisensory frame binding. Agonism, disinhibition, excitation, and nonlinear amplification in layer V recurrent circuits would necessarily lead to global multisensory frame aliasing errors, feedback synesthesia, and eventual perceptual overload.

Destabilization in thalamocortical feedback loops

The most potent psychedelics are 5-HT$_{2A}$ receptor agonists; the highest density of 5-HT$_{2A}$ receptors are in the dendrites of layer V pyramidal cells; layer V pyramidal cells bind information in feedback projections throughout the brain. Taking these factors into account it is reasonable to assume that psychedelic hallucinogenic activity is due to nonlinear signal destabilization and amplification via disinhibition recurrent layer V feedback projections. Psychedelic hallucination is achieved by partial or full agonism along recurrent layer V binding junctions; the introduction of a competing agonist in the 5-HT$_{2A}$ modulatory system leads directly to loss of inhibition, underconstrained perception, and self-sustaining excitation in autonomic sensory processing circuits. Destabilization of layer V projections is most acute where signal travels in recurrent loops or feedback circuits that resolve and react to incoming sensory data in real time. The primary circuits for binding real-time sensation include the cortico-striato-thalamo-cortical (CSTC) loops, and the more distributed cortico-thalamo-cortical feedback loops (or thalamocortical loops) which pass information from the cortex either through the basal ganglia or directly back into the thalamus for discriminating and gating attention of incoming signal flow. These loops can be described as attention-controlled feedback filters which drive and stabilize external perception and behavior. CSTC loops provide real-time sensory feedback for fine-tuning eye movements, motor reflexes, emotional responses, and cognitive value placed on stimulus.[17] Destabilization in signal coupling along thalamocortical feedback pathways will necessarily lead to problems with sensory gating, multisensory frame resolution, working memory, and seamless temporal aliasing.

There are specific entopic perceptual effects one would expect to see as a result of instability in thalamocortical feedback loops between the thalamus to the visual cortex, such as a subtle flickering or pulsing of light intensity; geometric grids and matrices; the perception of halos or auras around light sources; increased luminosity of reflective objects; the softening of line and texture resolution; and the inability to hold sharp focal contrast between foreground and background in depth perception.[18] Sensory filling in the visual periphery relies on fast temporal aliasing of signal for motion detection, and this timedependent temporal aliasing can be subverted by optical illusions which create a sense of movement in the periphery (Figs. 6, 23). A competing 5-HT$_{2A}$ agonist would necessarily disrupt the precise inhibitory timing in the cortical columns needed for peripheral edge detection and sensory filling, leading to shifting line and depth ambiguities in the periphery along predictable pulse cycles. If the rate of multisensory frame saturation or neutralization was slowed or interrupted by even a few milliseconds, incoming sensation would begin to layer over itself with increasing levels of smoothing, liquidity, and phantom frame echo decaying in the wake of sensation.[19]

5-HT$_{2A}$ receptor agonists can destabilize multisensory perception in a number of ways. The most general explanation is that 5-HT$_{2A}$ agonists introduce a competing excitatory impulse that disrupts the precise timing of sensory binding in the apical dendrites and recurrent circuits of the thalamus and cortex. Evidence indicates that 5-HT$_{2A}$ agonists promote a late release of glutamate from layer V pyramidal cells following strong incoming spike trains, resulting in the generation of asynchronous excitatory postsynaptic currents (EPSCs).[1,11,12] Asynchronous EPSCs in recurrent sensory circuits are normally helpful for resolving important perceptual data, but if the subject is unable to inhibit evoked EPSCs caused by exogenous modulators (hallucinogens), this late signaling action can lead to glutamate flooding and tonic sensory saturation in perceptual neural assemblies, which is consistent with manic self-sustained states of hallucinogenesis.[20]

There is evidence that 5-HT$_{2A}$ agonists lead to lateral disinhibition in the cortex by blocking presynaptic uptake of 5-HT at the lateral inhibitory synapse, or by overriding tonic GABA$_B$ inhibitory postsynaptic potentials (IPSPs) with asynchronous EPSCs at the lateral-inhibitory synapse.[21,22] Loss of inhibition at the lateral synapses in columns of the visual cortex would lead directly to shifting and wiggling in peripheral line, texture, and contrast resolution. As thalamocortical feedback circuits become increasingly disinhibited, they may fall into coherent self-sustaining states of under-constrained perception,[23] promoting phantom sensory activity such as hallucination and spontaneous dream filling in the corners of the eyes. In the disinhibited or under-constrained psychedelic state, mild stimulus may not provoke hallucinogenic response, but intense stimulation would drive sudden localized feedback coherence, signal amplification, and resulting frame saturation and latency errors. The sudden shift from stabilized brain focus to states of elicited, recurrent thalamocortical feedback excitation can be described in terms of a nonlinear, nonequilibrium phase transition caused by energetic sensory drivers.[15]

5-HT_{2A} cross-agonism and organism re-modulation

Looking beyond the cortex, it is worth mentioning that 5-HT_{2A} receptors are also found in the midbrain, olfactory systems, the brainstem, intestines, and all over the body in smooth muscles and cardiovascular systems. There is some evidence that 5-HT_2 agonists have a secondary effect at the locus ceruleans in the brainstem (LC), promoting adrenal activity in the presence of strong sensory drivers.[1] Sensory driving of adrenal release may promote a synesthetic burst of emotional intensity accompanying any strong multisensory experience. There is evidence that 5-HT agonist hallucinogens inhibit sensory gating in the thalamus, allowing more raw sensation to flood the cortex;[17] this is consistent with decreased gating and nonlinear feedback amplification in thalamocortical loops. A common early side-effect of hallucinogen use is stomach tightening and intestinal cramping; this is undoubtedly due to 5-HT_{2A} agonism interfering with modulation of smooth muscle contraction in the gut. 5-HT_{2A} cross-agonism in the intestines can lead to nausea and purgation, and reports of intense hallucinations typically increase immediately following release of intestinal discomfort.[24] This indicates that radical interruption and re-modulation of all 5-HT_{2A} pathways, from the intestines to the cortex, may be a common precursor to peak psychedelic experiences and states of intense bodily transcendence.

Because of the multiple systems affected by 5-HT_{2A} receptor agonism, it would be overly reductive to point to a single pathway as being responsible for full psychedelic activation. The synergistic effect of multi-layered 5-HT_{2A} agonism is felt subjectively as a throbbing or pulsation of energy which suffuses the entire body, builds in strength and complexity, and culminates in a cathartic multisensory release of highly charged transformative content. At the sensory level, glutamate flooding saturates perception. At the emotional level, adrenal response drives sensual intensity. At the frame level, aminergic interference leads to disorientation and loss of temporal ego cohesion. At the cognitive level, aminergic destabilization drives irrationality, depersonalization, and hallucinogenic dream states. At the circulatory level, 5-HT_{2A} agonism promotes vasoconstriction and increases blood pressure. At the somatic level, an interruption of digestive functioning drives metabolic function and energetic intracellular signaling. At the organism level, the holistic effects of prolonged 5-HT_{2A} agonism become nonlinear, meaning they feed back on themselves and begin to generate complex energetic output in response to sensory input over time. This multi-layered organism activation can be formally described as a runaway biological feedback process, or a nonlinear cellular signaling loop, which drives increasing cellular activity and complexity over the full duration of synergistic agonism.

Chapter 09

What is Nonlinear Hallucination?

Psychedelic Information Theory invokes nonlinearity to describe the perceptual effects of hallucination, but the term nonlinear has a variety of definitions which are sometimes confusing or unclear. To clarify the nonlinearity of psychedelic hallucination, the following is a description of formal nonlinear dynamics, broader definitions of nonlinear systems, and how each of these definitions may apply to psychedelic perception.

Nonlinear Systems

Nonlinear systems can be defined in terms of the complexity of output in proportion to input, also described in terms of sensitivity to initial conditions. The output of changes in a linear system are simple and can be modeled with a line on a graph. In contrast, the output of a nonlinear system feeds back on itself and becomes chaotic and complex; simple small changes in initial conditions will result in unpredictable and exponentially divergent data sets that cannot be easily predicted. In mathematical terms, the results of a nonlinear system begin to bifurcate, diverge, or split into multiple possible data points the farther out you attempt to resolve them. The results of a nonlinear system cannot be modeled with a linear function because linear functions plot sequential or additive complexity; nonlinear functions plot exponential or geometrically expanding complexity. The mathematical study of nonlinear systems has resulted in chaos theory, complexity theory, and the analysis of self-amplifying recursive systems such as fractals and cellular automata. Renderings of nonlinear systems output are considered to be of high intrinsic beauty, (Fig. 14)[1] and the repeating forms and patterns are often perceived as spiritual or mystical because they are isomorphic of chaotic or nonlinear systems in biology, nature, and the cosmos.

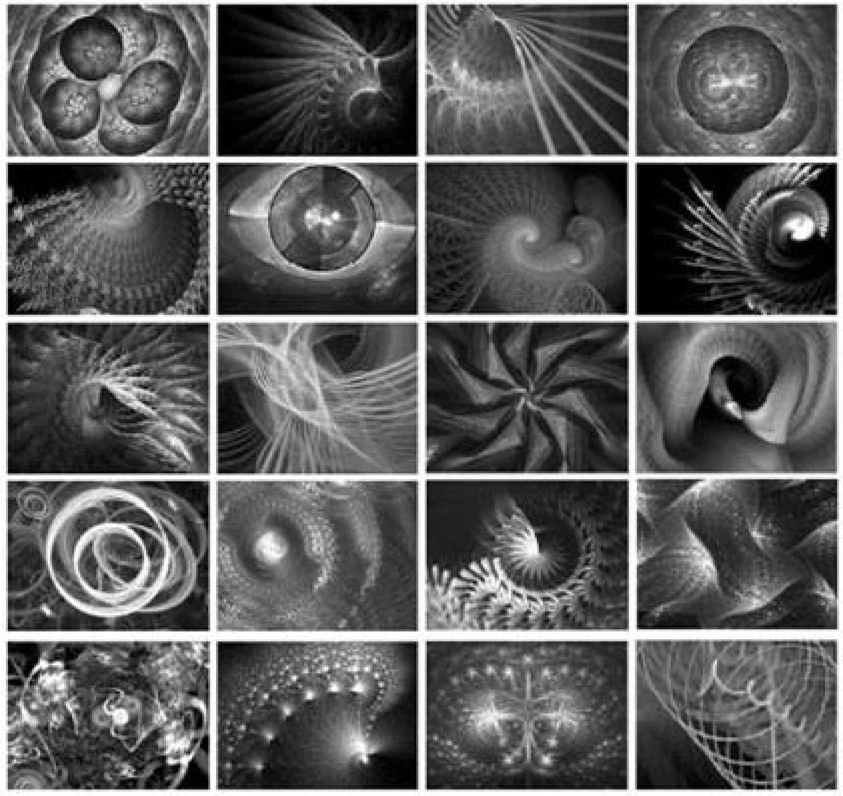

Figure 14. "Electric Sheep" fractals selected for an aesthetic voting experiment. Images chosen for intrinsic natural beauty. From Taylor, 2008.[1]

Nonlinear Consciousness

The physical world is a complex nonlinear system, but human consciousness perceives reality as a single linear sequential narrative that moves predictably forward in time. The linearity of perception is an indication that consciousness is producing stable, predictable output. If perception suddenly diverges into multiple unpredictable outputs for the same linear input, this is an indication that consciousness has destabilized and become nonlinear. A video feedback loop is an good example of a nonlinear perceptual system; each frame captures itself and the receding previous frame, and then itself and two receding frames, and then itself and three receding frames, and then itself and four receding frames, and so on, feeding back on itself at 30 frames per second until complexity recedes into chaos and infinity (Fig. 15). This is the mathematical definition of nonlinear system generating fractal complexity, or chaos, through an iterated map or recursive frame-stacking feedback loop.

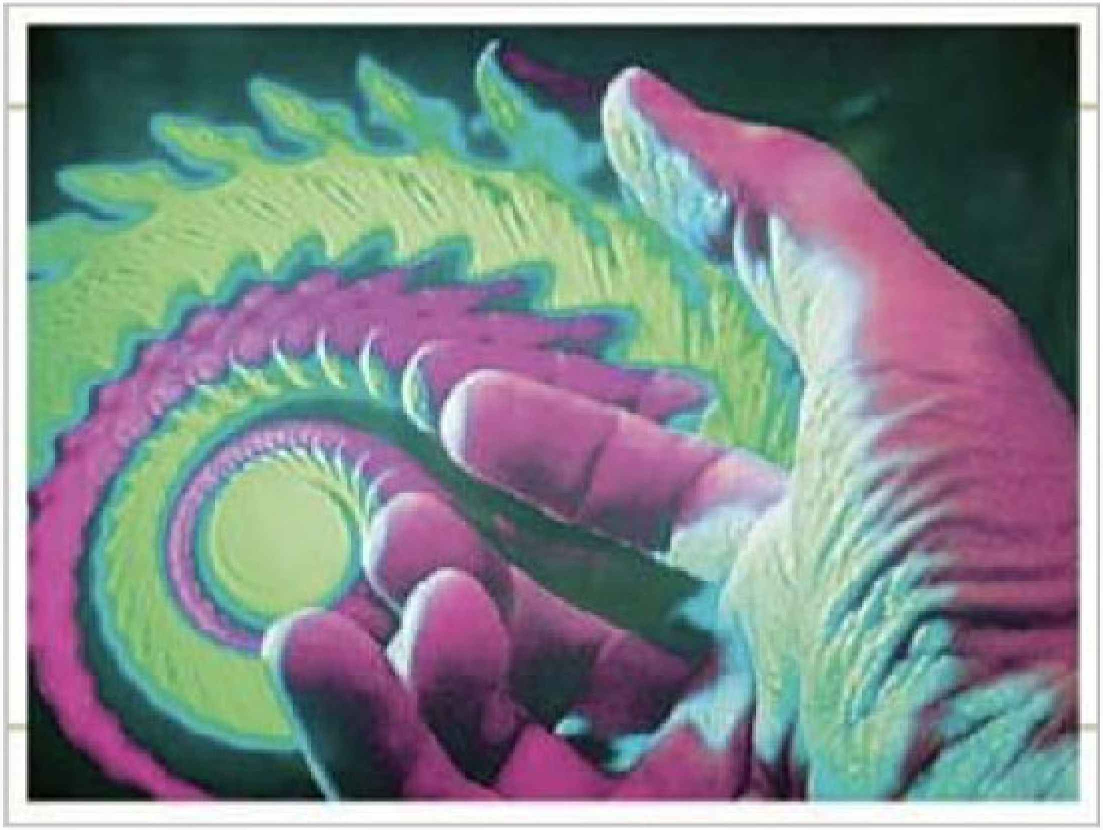

Figure 15. A video feedback loop creates a nonlinear system isomorphic of a fractal, where from recedes inward on itself, spiraling towards infinite complexity in under a second. From Hofstadter, 2007.[2]

Other examples of nonlinear consciousness may be less classically nonlinear, meaning not generating exponential complexity, but still lacking in linear formalism. For instance, consciousness may perceive itself to be in multiple places at once; it may perceive multiple data sets for the same input; it may see multiple different perspectives of the same scene; it may move sideways or backwards or completely outside of linear time. These would all be considered nonlinear perspectives of consciousness. Dreaming can be associatively nonlinear, which means narrative content moves unpredictably from state to state while retaining some tangential linearity. Psychedelics are famous for being progressively nonlinear, which means incoming sensation saturates perception and begins to stack over itself, generating increasing complexity of sensual intensity through time.

Phenomenology of Nonlinear Perspectives

By definition, a nonlinear system produces results with increasing complexity over time. In a linear perspective a human will parse a literal analysis of each object and then move on to the next object. In a nonlinear perspective the subject produces increasingly complex perceptual results for each object held in focus for the duration of that focus. For instance, a subject staring at a rock in a linear state may notice interesting shapes, textures, or colors; in a nonlinear state that same rock may provoke thoughts and visions of the birth of the universe and the origins of suns and planets and all solid matter leading up to the formation of that very rock. The linear perspective sees literal, formal attributes of the rock in the moment; the nonlinear perspective sees the rock as a temporary clump of energy bound in a cosmic information system receding forwards and backwards to the beginning and end of time. The metaphor of seeing the entire universe in a rock can also be applied to emotional epiphanies, autobiographical insights, passing fantasies, paranoid delusions, and so on. Whatever the focus of nonlinear perception, the object held in focus will be amplified with increasing salient complexity the longer it is held in focus.

The endless complexity of nonlinear perception can cause the subject to fall into perceptual loops which spiral, bifurcate, and recur with the formal qualities of a fractal (Figs. 1, 14). Frame information stacked in nonlinear psychedelic perception iterates on the order of 2 to 16 times a second, depending on drug and dose range, allowing for increasingly complex renderings of nonlinear information to the point of total sensory overload. Because of the quickly bifurcating complexity of nonlinear object analysis, the information produced in a nonlinear state emerges into consciousness much faster than information produced in a linear state. The production of fast, nonlinear data in the psychedelic state is often described as a download; an inconceivably large amount of information that compiles into memory almost instantly. The only way this amount of information can be processed through the brain is via nonlinear analysis; linear attempts to formalize psychedelic nonlinear information into words or pictures typically fall short of capturing the holistic perspective.

Nonlinear Hallucination

There are many colorful examples of nonlinear hallucination. Seeing geometric grids, webs, and spirals are nonlinear artifacts of destabilization of coupled oscillators in optic networks. Subjective reports indicate that DiPT produces unique nonlinear pitch transposition in audio networks, causing subjects to hear sounds modulated down an entire octave or more depending on the pitch and volume of stimulus. Auditory echoes, visual motion trails, and phantom tactile sensations are recursive artifacts of perceptual frame feedback. Perceiving multiple perspectives for the same input is a nonlinear bifurcation of multisensory coherence. Perceiving dream images superimposed over external space is nonlinear destabilization of visual memory recall. Seeing the formal boundaries of solid objects bend and melt into each other is a nonlinear destabilization of contrast and edge detection. Hearing a voice on the television or radio speaking directly to you is a nonlinear destabilization of semantic parsing and sequencing. Skipping time, missing time, or moving sideways or backwards in time is a nonlinear destabilization of temporal frame buffering. The basic tenet of psychedelic hallucination is that hallucinations move progressively from linear to nonlinear complexity depending on dose range and duration of effect; the higher the dose of the hallucinogen, the more disproportionately nonlinear, unpredictable, and complex perception will become in response to stimulus over time.

Chapter 10

Entopic Hallucination

Entopic hallucinations, or phosphenes, are one of the most commonly reported visual effects of psychedelics. Phosphenes are a sensation of light caused by excitation of the retina by mechanical or electrical means. Pressure phosphenes can be created by applying pressure to the eyeballs through closed eyelids; flicker phosphenes are created in response to stroboscopic pulses of light; kinetic phosphenes are created in response to physical impact to the head, sometimes referred to as seeing stars. Entopic hallucinations are differentiated from eidetic or photographic hallucinations in that they originate within the neural connections between the eye and cortex (Fig. 16), as opposed to emerging within the cortex or midbrain. There is evidence that entopic phosphene patterns have influenced human cultural and religious archetypes since 10,000 BCE (Fig. 2).[1,2,17]

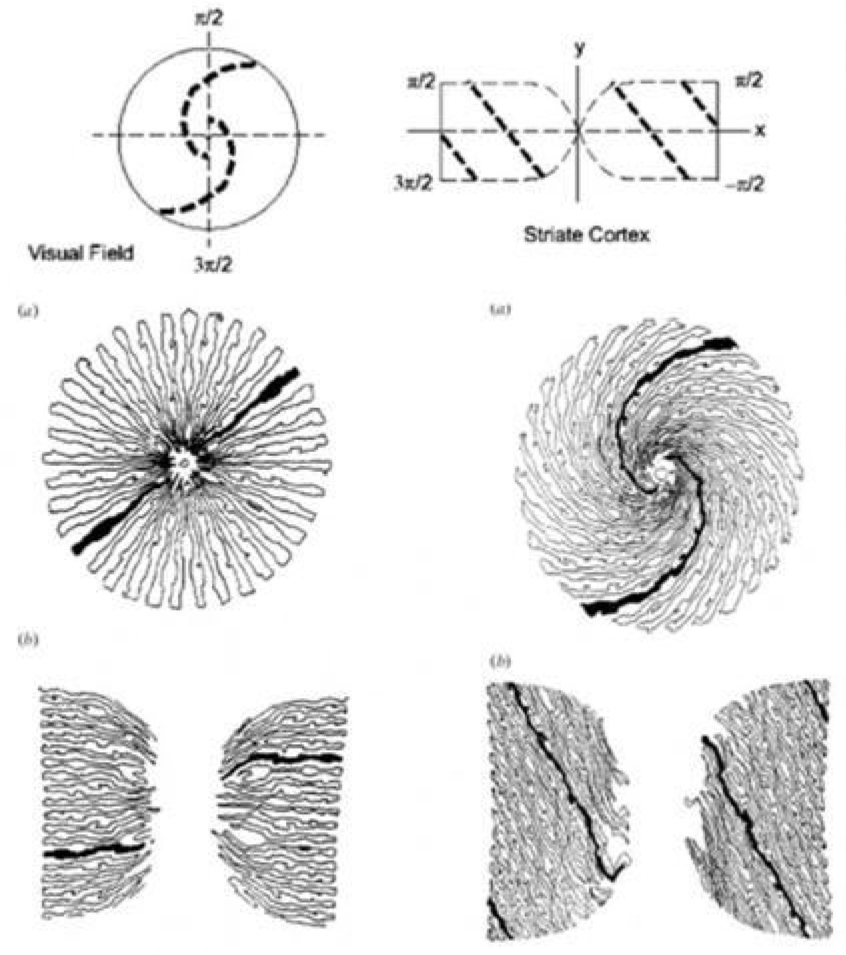

Figure 16. Spatial-relationship mapping between retinal cells with associated areas of the striate (visual) cortex. Images hitting the funnel and spiral ringed networks of the eye must be translated to lines and shades in the cortex for visual rendering. Geometric hallucinations, phosphenes, and entopic form constants arise from destabilization in (a) distance and (b) orientation selective retinal-cortical coupling. From Bressloff, 2002, Gutkin 2003.

Entopic hallucinations fall into predictable geometric patterns and can be measured by formal properties such as form constant, flicker rate, rotation, drift, and decay. Common phosphene forms include web, grid, checkerboard, clover-leaf, honeycomb, spiral, funnel, or more amorphous floating blobs and stars (Fig. 17).[3] Phosphene patterns may match recurring patterns in the natural world, such as cells, stars, sand dunes, flowers, clouds, and snakeskin. Evidence suggests that the form constants of phosphenes are directly related to spatial relationships between the ring-like structure of the retinal cells and the grid-like or columnar neural structures of the visual cortex. The spontaneous production of geometric hallucinations is due to excitation and loss of stability in these retinal-cortical feedback coupling pathways. The transition from seamless visual aliasing to spontaneous geometric patterns can be described as a transcritical sensory bifurcation reflecting the spatial organization of the recurrent network.[4,5,6]

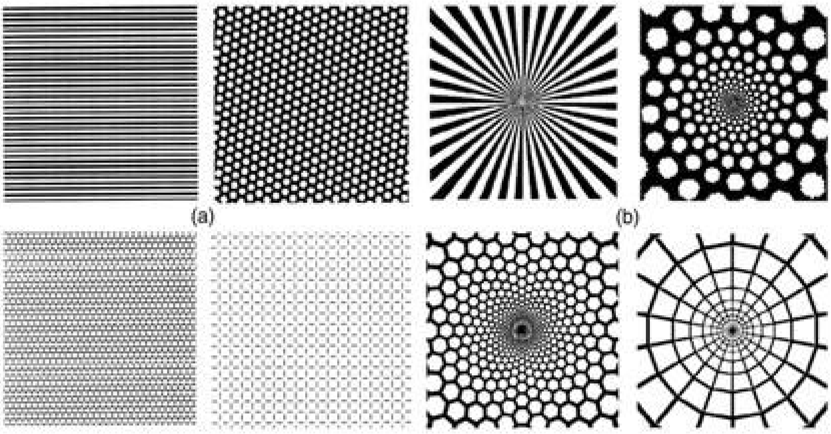

Figure 17. Geometric hallucinations, or flicker phosphenes, appear in form constants arising from destabilization in (a) distance and (b) orientation dependent retino-cortical signal coupling. From Bressloff, 2002., Gutkin 2003.

Pulses in the same frequency range as brain waves (theta to gamma) are most effective in producing flicker phosphenes.[3] Flicker phosphenes created by stroboscopic lights or mind-machines tend to be more amorphous at low frequencies (1-4hz), tend to fall into web, spiral, or cloverleaf patterns at medium frequencies (4-9hz), and tend to lock into grid, honeycomb, or checkerboard patterns at higher frequencies (9-16hz+). Flicker phosphenes will have slow lateral drift at lower frequencies; a rotational drift at medium frequencies; and will maintain stability or produce fast lateral drift at higher frequencies.[7] These phase-related transitions in standing wave shape are also seen in Chladni patterns created in vibrating plates (Fig. 31). Presumably any technology which uses pulsating frequencies to produce phosphenes, such as transcranial magnetic stimulation (TMS), must also use pulses corresponding to the frequency range of human temporal aliasing to produce substantially stabilized phosphene forms.[8]

Flicker Phosphenes and Hallucinogenic Interrupt

Taking what we know about the production of geometric hallucinations in response to pulse activity within specific frequency ranges, it is possible to extrapolate that the multisensory interrupt of any hallucinogen must fall into the same range of @5-40hz, which is the general frequency range of human consciousness, to produce phosphenes. According to the Control Interrupt Model of psychedelic action, any drug which produces a multisensory interrupt within the frequency band of waking consciousness will also necessarily produce flicker phosphenes and be considered hallucinogenic. If the multisensory interrupt is too slow or too fast, the drug may still be considered psychedelic, empathogenic, entactogenic, or dissociative, but it will be less likely produce significantly realized geometric flicker hallucinations. This same principle can be applied to audio and tactile sensory binding; any periodic interrupt within the frequency band of human sensory consciousness will necessarily induce field-like hallucinations with stable form constants and properties related directly to the interrupt frequency.

The evolution of flicker phosphenes can be described formally by the geometrical self-organizing feedback patterns seen in fractals (Figs. 1, 14), cellular automata (Fig. 18), or patterns arising from standing wave interference (Fig. 31). Under the influence of psychedelics, flicker phosphenes grow in intensity, become more elaborate, and become more structurally resolved over time.[3] It can be assumed that this is because the modulatory interrupt of a hallucinogen is being applied directly to the sensory binding pathways via pharmacological interaction as opposed to being applied to the retinal or cortical networks via external pulse stimulation. Because the modulatory interrupt of psychedelics is pharmacological, it is more difficult for the subject to fend off or ignore the interrupt to retain multisensory stability; the very pathways that maintain stability are the pathways which are being interrupted. In a very physical way, the modulatory interrupt of the hallucinogen is hijacking the sensory signaling pathways and overriding them with its own modulatory frequency. Because of this, the influence of the hallucinogenic flicker interrupt becomes explicit in sensory rendering; the subject may literally see or feel the pulsating geometric field interference as a fully embedded aspect of their perceptual reality.

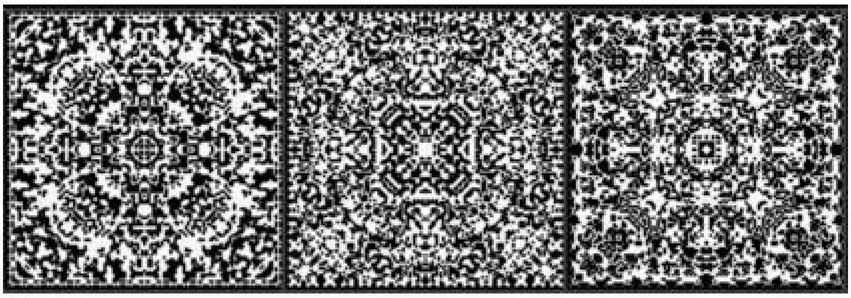

Figure 18. Examples of programmatic cellular automata. Repetition of simple algorithms create complex patterns of archetypal beauty. Levitated.net, 2010.

Flicker phosphenes are the product of neurochemical saturation and have substantial signal decay. There is evidence that electrically stimulated phosphenes take as long as 10-15 seconds to fully fade once the periodic stimulus is removed.[9] Overlapping stereoscopic phosphenes will naturally create decaying interference patterns approaching fractal complexity. It can be assumed there is a saturation of signaling molecules that builds up at the site of synaptic interruption that persists for some period of time following each interrupt. The pulse of each interrupt can be described in terms of saturation attack and decay; the fade of each interrupt can be described in terms of saturation sustain and release (or ADSR envelope).[10] Full saturation would mean a complete white-out of sensory information at the interrupt site; zero saturation would mean the interrupt site is cleared of signaling molecules and is presenting a darkened resting state. Saturation at the interrupt site increases and decreases in intensity over the period of each interrupt; this change in chemical saturation over the duration of each interrupt is perceived as a flicker or pulse of sensory intensity.

Because a hallucinogenic interrupt pulses at many cycles per second, and because each pulse can have a saturation decay of many seconds, phosphenes will naturally drift laterally or radially across the visual field as they decay, creating overlapping webs of many arising and fading geometric patterns all visible within a single perceptual frame. This creates the formation of complex standing interference patterns. The web-like interference of multiple arising and decaying geometric grids creates a 3D meshwork that allows complex eidetic shapes to materialize spontaneously within the quickly morphing wire-frame (Fig. 20). Visual saturation is most intense at the interstices of the wire-frame mesh, creating the perception of bright dots or scintillating jewels where patterned lines overlap and intersect into nodes. These saturated pixel groups may correspond to actual hot-spots of neural activity saturating columns of the visual cortex. These hotspots are produced spontaneously in the wake of stimulus, creating a flood of glutamate wherever shafts of apical dendrites intersect with lateral projections from proximal neural columns.[18] Glutamate flooding at dendritic columns of pyramidal neurons is presumably the result of asynchronous glutamate release following 5-HT$_{2A}$ receptor agonism.[19]

It is widely assumed that geometric hallucinations and flicker phosphenes originate between the optic track and cortex, but some subjective reports of psychedelic experimentation also describe a fast pulsation or rhythmic jitter felt in the muscles around the eyes. This sensation is most acute in the outside corner of the visual periphery, specifically along the lateral rectus and the junction where the inferior oblique passes over the inferior rectus (Fig. 19). This optical pulse may be difficult to discern in early parts of a psychedelic session, but becomes more acute and easier to sense as the session wears on. This rapid pulsation may be related to modulatory interrupt and saturation at the cortical columns that control optic muscles, generating a chain reaction in neural transduction felt as a muscle twitch or throb. Periodically interrupting the eye's finely timed saccades with a muscle twitch or pulsation may be enough to produce phosphenes.

Increasing or decreasing optic pressure naturally produces phosphenes; 5-HT$_{2A}$ agonism decreases ocular pressure. In his experiments with phosphenes in the mid 1800s, Johannes Purkinje applied an aqueous extract of belladonna (scopolamine, atropine) directly to his eye to produce phosphenes. Because the effect was localized, Purkinje proposed that phosphenes may be related to cycloplegia, or partial paralysis of the eye muscles.[20] Given these reports, it is reasonable to assume that any interruption of visual motor control, interruption of optic signal transduction, or change in optic pressure will produce phosphenes. Phosphenes generated by changes in ocular pressure or muscle twitch would be considered synesthetic representations of pressure waves rippling from intraocular fluid into receptive nerve junctions.

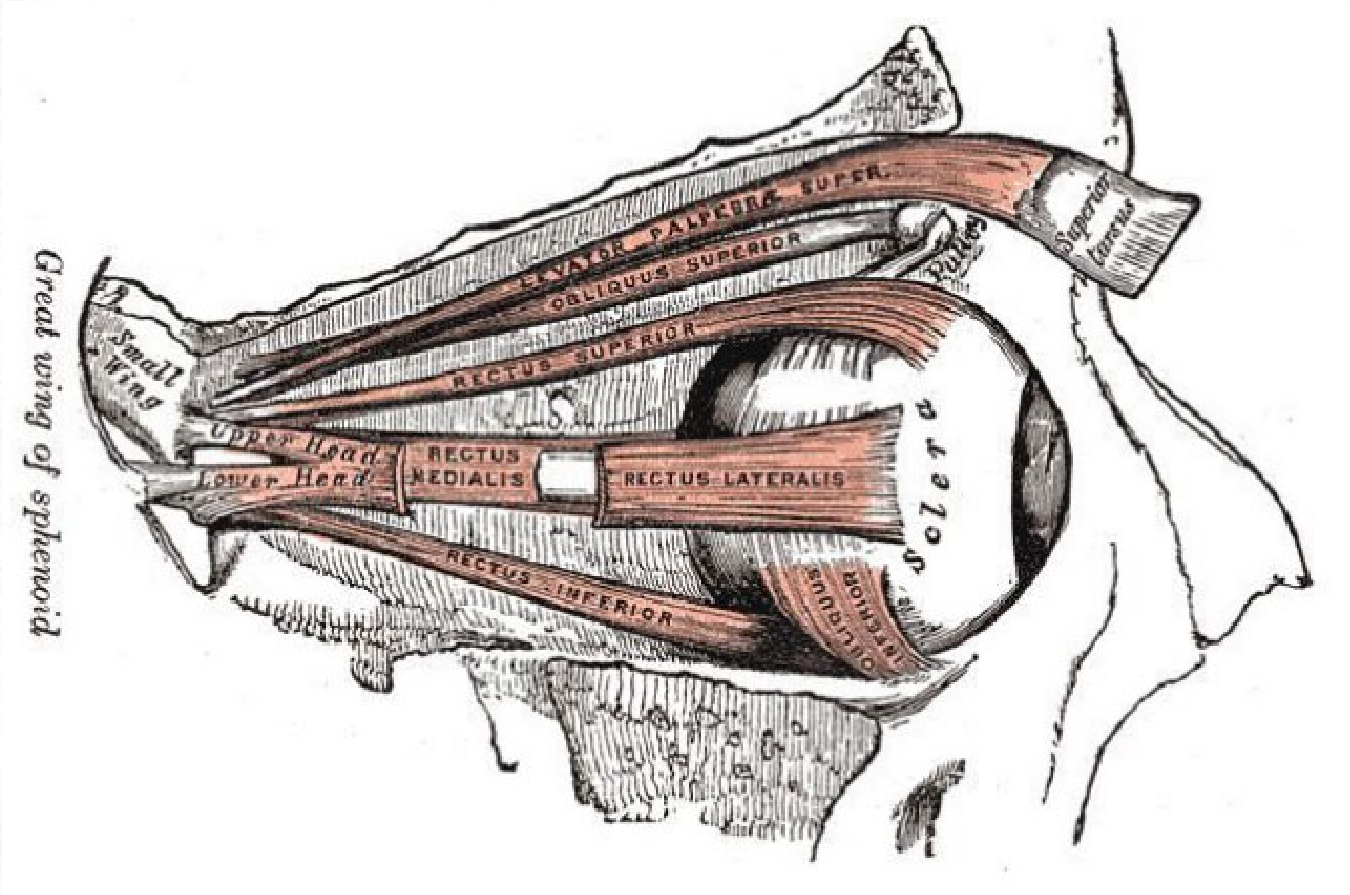

Figure 19. Muscles of the eye. Some subjects on psychedelics report pulses or rhythmic twitching in optic muscles that control focus, specifically the lateral rectus and inferior oblique. These pulses may generate pressure phosphenes related directly to frequency of pulsation. From Grey's Anatomy.

Entopic vs. Eidetic Hallucination

Geometric hallucinations, or phosphenes, are considered to be entopic, meaning they are a product of excitation and destabilization in spatial coupling between neural assemblies in the retina and visual cortex, and produce geometric patterns similar to wave interference patterns. Entopic hallucinations can be contrasted with eidetic hallucinations, which are more fully formed images that appear from visual memory or imagination. Psychedelic eidetic hallucinations are often more explicitly personal than the abstract geometric forms associated with flicker phosphenes. Over the course of a psychedelic session, hallucinations will start with flicker phosphenes and then increase in complexity from entopic to eidetic content, often containing a seamless mixture of the two. It can be assumed that eidetic hallucinations only begin once serotonergic modulation of the PFC has been sufficiently interrupted to allow cholinergic modulation of internalized mid-brain visualization to come to the fore.[11] The transition from entopic to eidetic hallucination is also associated with a transition from the high frequency beta or gamma state to a lower frequency alpha or theta state.

Meditation and auto-hypnotic exercises are targeted to produce states of hypnagogia associated with theta waves and entopic hallucination. Drugs which naturally drive theta waves in the brain are called hypnotics. Some psychedelics are naturally hypnotic, others are hypnotic only in sensory deprivation or under the influence of a theta-band periodic driver.[12] The hallucinogenic tea ayahuasca is a mixture of a high-frequency interrupt psychedelic (DMT) and a low-frequency hypnotic driver (the beta-carbolines harmine and harmaline, among others). This synergistic blend of high-beta interrupt and slow-theta attenuators means that ayahuasca should promote both fast beta geometric flicker phosphenes as well as slow eidetic theta dream snippets. This prediction can resolve paradoxical EEG analysis of subjects under the influence of ayahuasca, which sometimes indicates increased power in high frequency beta and gamma coherence,[13,14] but in the context of shamanic ritual shows increased power in slow-wave theta activity.[15]

Eidetic hallucination is considered to be rendered photographically or presented as a 3D virtual model. In psychedelic intoxication, a strange conversion of eidetic and entopic phenomena can occur when an eidetic image or symbol reproduces into a marching grid or kaleidoscopic network of repeating symbols with a juxtaposed eidetic image emerging within the repeating superstructure. For example, a subject may hallucinate a geometric grid of quickly spinning colored triangles, and as those triangles flicker across the visual field they suddenly cohere into a 3D wire-frame mesh of a more fully-realized eidetic snapshot of a human body or face. In addition to triangles, the overlaying grid may be composed of dots, circles, honeycomb, spiders, insects, centipedes, worms, snakes, reptiles, lizards, question marks, swastikas, teeth, piano keys, skulls, flowers, leaves, stars, eyes, billiard balls, dice, playing cards, human faces, alien faces, dancing elves, skeletons, clowns, jesters, writhing bodies, branching trees, cells, bacteria, paisleys, DNA, Japanese kanji, Byzantine tile patterns, Mesoamerican brick patterns, Native American totem patterns, Polynesian tiki patterns, and similar repeating archetypal forms.[16] The fast flicker rate and embedded kaleidoscopic nature of this type of compound hallucination often defies formal description or the ability to accurately capture in art or memory. The hallucinogenic perception of a complex embedded symbolic grid or kinetic fractal superstructure is unique to the psychedelic experience; it may be the visual essence of what makes an experience authentically psychedelic.

Chapter 11

Eidetic Hallucination

Psychedelics can produce many types of hallucination, including geometric webs and grids;[1] distortions of space and time;[2] and photographic images of objects, people, or scenery. Hallucinations with a photographic, animated, or film-like clarity are called eidetic hallucinations, or eidetics for short. Eidetics share many of the formal qualities of dreams, visual memory, and imagination, and may be the most alluring aspect of experimenting with hallucinogens. Eidetic hallucinations rise and fall like dream snippets, rarely holding form for more than a few seconds before fading or shifting into another form. Eidetic objects, scenes, or people that become solid and retain their shape for an extended period of time are called frank or concrete hallucinations. Concrete hallucinations are often solid, immersive, indistinguishable from reality, and share many of the qualities of lucid dreaming, sleepwalking, and dementia.

The most commonly reported eidetic hallucinations seen on psychedelics are of people, faces, skulls, jaguars, snakes, plants, blooming flowers, spirits, aliens, insects, and other similar archetypes. Eidetic hallucinations can sometimes take the form of entire virtual worlds, spirit dimensions, invisible landscapes, and so on. Eidetics often emerge within a pre-existing entopic interference pattern that grows in intensity over time to produce more photographic or 3D rendered objects (Fig. 20).[1] Eidetics under the influence of psychedelics are most often reported with eyes closed or while sitting motionless in meditative trance. On high doses of psychedelics eidetic hallucinations may materialize with eyes open on any surface, pattern, or texture that's gazed at for more than a few seconds.[3]

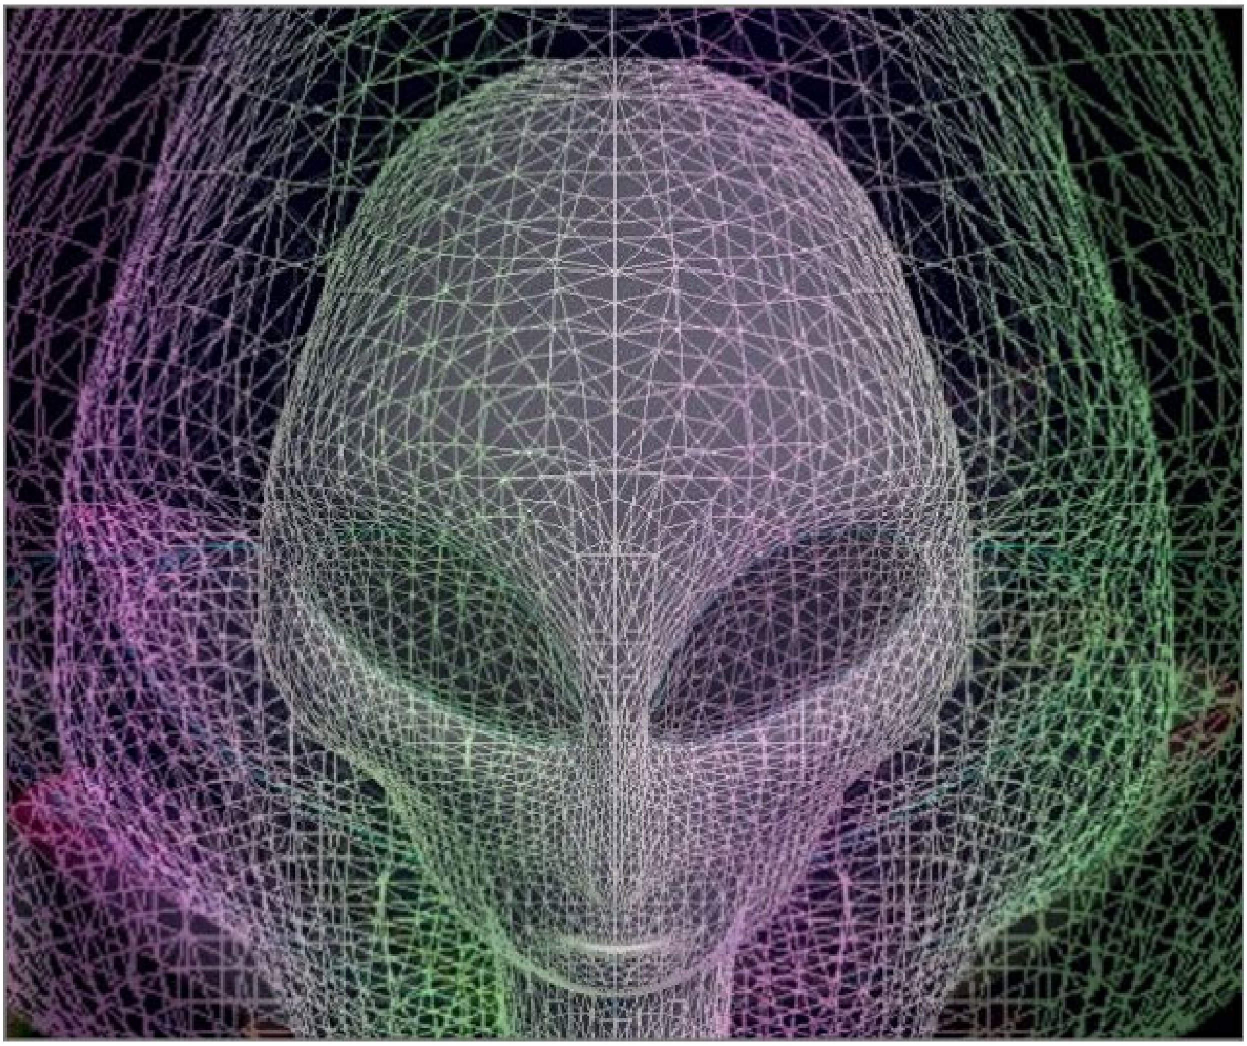

Figure 20. Eidetic tryptamine hallucinations, like this alien, typically emerge as snapshots or animations within a larger geometric interference pattern.

Psychedelic eidetics are progressive, which means they begin as non-durable form arising from patterns or noise, and then over a period of seconds drift, smooth, or lock into formal qualities which can be recognized as salient shapes. The process of smoothing or locking onto an eidetic form in a psychedelic hallucination requires some minimal amount of focus and concentration to sustain. The eidetic image may materialize, ooze, or pulse into clarity in response to the subject's concentration and focus, developing slowly like a Polaroid photo or film-reel fade-in. Losing concentration for an instant can cause the eidetic image to fade or shift into another image. Holding the eyes still will increase intensity of progressive eidetic imagery; blinking or flicking the eyes from side-to-side will wipe the visual memory buffer and cause eidetic images to fade; holding the eyes still again will cause previously held images to spontaneously rematerialize.[4]

The Hippocampus, ACh, Memory, and Dreaming

The processes of dreaming, memory storage, and memory recall are managed by the hippocampus.[5] The hippocampus receives perceptual information from the frontal cortex but is also wired tightly into the emotional limbic system and medial temporal lobe; which is why strong memories always have an emotional component.[6] Since the hippocampus is central in the formation, consolidation, and reconsolidation of all salient memory, we can also assume it is also the source of salient eidetic hallucination. The hippocampus is most active while awake and while dreaming. The process of moving from waking to sleeping is associated with a move from high beta or alpha activity down to slower theta and delta ranges. Deep sleep is associated with slow delta waves and low energy activation, while REM sleep and dreaming begin to produce beta activity and energy profiles similar to those seen in waking activity.[7]

Nocturnal dream activity is a process of memory consolidation.[8] In deep sleep and REM the stress chemical cortisol decreases communication between the hippocampus and neocortex,[9] and the process of REM and dreaming is stimulated by acetylcholine release.[10] Acetylcholine (ACh) is the primary messenger of the brain's cholinergic system, essential to hippocampal modulation of memory compression and recall (Fig. 21). Sleep-onset, sleeping, and dreaming are associated with an increase in ACh modulation of the brainstem and medial temporal lobe; this occurs along with a proportional decrease in serotonin, norepinephrine, and aminergic activity in the pre-frontal cortex (PFC). The interplay between these two systems acts like a tide between waking and sleeping worlds. Drugs which increase aminergic activity, such as antidepressants, should also decrease dreaming.[11] Similarly, the prolonged suppression of cholinergic activity and REM sleep due to deprivation or extended amphetamine use creates psychotic episodes which may be defined as bursts of dream activity erupting spontaneously into waking states.

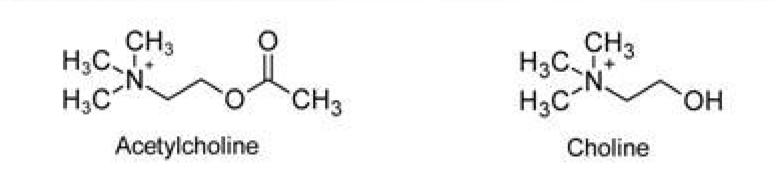

Figure 21. Acetylcholine (ACh) modulates the medial-temporal lobe during memory storage, recall, and dreaming. Eidetic imagery in hallucination is associated with high ACh modulation.

To describe the functional interplay between aminergic waking states and cholinergic dreaming states, J. Allen Hobson has proposed a three-dimensional AIM state-space model.[11] The interference between aminergic and cholinergic systems can be modeled by plotting the overall activation of the brain (A, high vs. low energy), the input of sensory signal (I, internal vs. external), and the signal modulation (M, aminergic vs. cholinergic). Using this AIM model we can present a snapshot of the waking, dreaming, or hallucinating brain in a graphic context (Fig. 22). A waking brain would be high in activity, input gated externally, with high aminergic modulation. A dreaming brain would also be high in activity, but input gated internally and high cholinergic modulation. Similarly, states of deep sleep, mania, and psychosis can also be described.

According to the AIM model, eidetic hallucination in a psychedelic session will not begin until external serotonergic modulation is sufficiently interrupted to allow internally gated cholinergic activity to rise to the fore of consciousness. Remaining motionless, closing the eyes, or sitting in a quiet darkened environment will stimulate the onset of eidetic hallucinations on psychedelics;[12] this is presumably because darkened stillness promotes sleep onset and an increase in internally gated cholinergic activity. The longer a subject under the influence of psychedelics remains motionless, the more photographically rendered the hallucinations will become. When the hallucinating subject rouses from trance and begins to move again, hallucination will lose photographic quality and return back to more generic entopic forms.

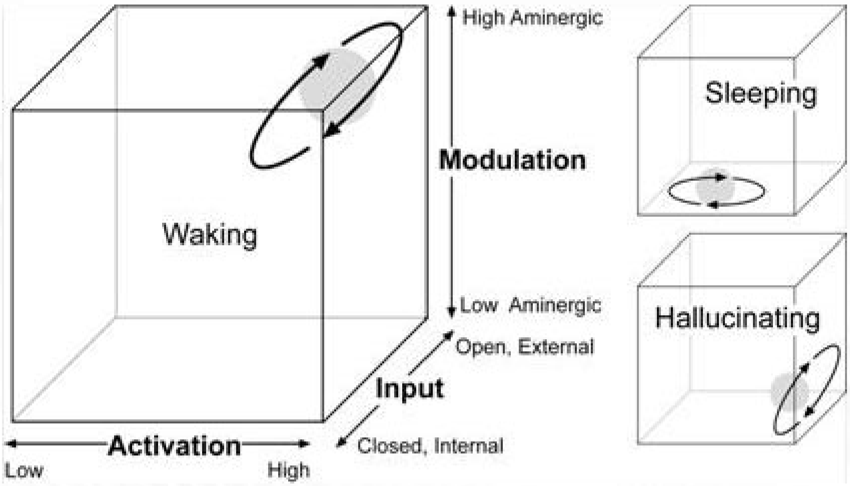

Figure 22. Hobson's AIM model shows patterns of (A)ctivation, (I)nput gating, and (M)odulation in various states of consciousness. Dreams and eidetic hallucination are associated with low aminergic and high cholinergic modulation.[11]

The ACh promotion of dreaming and REM has been demonstrated in animal research,[10] but only subjectively reported and presumed in humans.[22] Subjective reports of combining both the dissociative ketamine and the psychedelic LSD with pre-doses of galantamine and choline (both acetylcholine promoters) indicates that ACh promoters facilitate emotionally intense eidetic hallucinations, sometimes uncomfortable or unpleasant in nature, emerging beyond the subject's capacity to control.[13] This demonstrates that the production of eidetic imagery in response to ACh modulation is a spontaneous and automatic function of memory consolidation that cannot be easily controlled by the will or intent of the subject. The spontaneous production of salient eidetic memory makes psychedelics a useful tool in psychotherapy,[14] but the uncontrollable flood of eidetic imagery may not always be pleasant for the subject. States of intense eidetic hallucination may be associated with memory regression, imprinting, reconsolidation, and neuroplasticity.[15]

Anticholinergics, Concrete Hallucination, REM

Hallucinogens which target ACh receptors are reported to produce very vivid waking dreams and concrete hallucinations. Anticholinergics cause drowsiness, but at high doses also induce a disruptive sleep and a qualitatively unique form of delirium.[24] The commonly reported anticholinergic hallucinogens are the tropane deliriants atropine and scopolamine; found in deadly nightshade, belladonna, *datura*, Jimson weed, and members of the *Solanaceae* family.[16] Muscarine from the *Amanita muscaria* mushroom also interacts at the muscarine ACh receptors as an agonist. Tobacco also targets ACh receptors, but nicotinic ACh receptors instead of muscarinic receptors.[17] All plants and pharmaceuticals which target the cholinergic system are reported to be hallucinogenic at high enough doses. Cholinergic hallucinations are unique in that they may erupt into consciousness fully formed like dreams or fevered delusions.[18] In contrast, tryptamine psychedelics have progressive levels of entopic or erratic hallucination before reaching the level of concrete hallucination. Although *datura* and tobacco are common admixtures of traditional Amazonian ayahuasca preparations, experimentation with plants and drugs that target the cholinergic system at hallucinogenic doses is physically very uncomfortable and potentially lethal.[16,21]

Concrete hallucinations are similar to symptoms of dementia in that the subject literally cannot tell delusion from reality. Like a sleepwalker, the subject may think they are at the supermarket when they are actually looking into a closet. Psychedelics may produce this state of disorientation, but it is more commonly associated with dissociatives, deliriants, and pharmaceutical antihistamines or sleep aids. Suppression of REM sleep is associated with psychotic disorders,[23] and sleep deprivation for as few as three days can cause spontaneous periods of concrete hallucination and waking delusion.[19] Mixing anticholinergics with REM suppression can create highly realized waking lucid dreams and experiences of leaving the body and entering into parallel realities.[20] This indicates that periodic ACh REM consolidation of eidetic memory over the course of 24 hours is necessary for maintaining stability of consciousness. Activating eidetic memory consolidation with the use of psychedelics and extended REM trance-induction may be therapeutic for subjects suffering from depression, anxiety, or psychosis due to PTSD, insomnia, and other stress-related sleep disorders. Conversely, using psychedelics as stimulants to avoid sleep may lead to negative plasticity and persistent psychotic disorders.[15]

Chapter 12

Erratic Hallucination

Hallucinations have formal properties that can shed light on their origins. Entopic hallucinations are characterized by geometric forms originating in the retina and optic tract.[1] Eidetic hallucinations are characterized by photographic images originating from the hippocampus and medial temporal lobe.[2] There is also a third type of hallucination not covered by these other formal categories; erratic hallucinations, or hallucinations originating in the loss of multisensory frame stability. Optical illusions that exploit rendering ambiguities in peripheral vision can be described as erratic hallucination. Tinnitus, or phantom ringing or buzzing in the ears can be described as erratic hallucination. Parasthesia, or phantom tingling sensations due to oxygen loss or nerve trauma can also be described as erratic hallucinations.

Like entopic hallucination, the origin of erratic hallucination is a destabilization of multisensory processing and sensory signal coupling. Erratic hallucinations caused by 5-HT$_{2A}$ agonism include wiggling and drifting of line and shadow; frame stacking and recursive frame cascading; and temporal and spatial disorientation caused by loss of multisensory cohesion. Erratic psychedelic hallucination begins at low doses with simple formal boundary errors, and becomes more acute at higher doses, leading to the total loss of multisensory frame stability. Loss of multisensory frame stability under the influence of psychedelics resembles states of senility and schizophrenia.

Breathing Walls, Melting Textures, Creeping Carpets

Subjects under the influence of hallucinogens report breathing walls, creeping carpets, and melting textures. These effects are all similar in that they represent a loss of stability in sharp line, contrast, and texture detail in visual memory. This can be described as a rendering ambiguity error, and indicates a drifting of contrast information both laterally and radially across the cortex. This drifting in the visual field is most prominent in the periphery where the retinal blind-spots are working with incomplete data to begin with. This orientation ambiguity is exploited in optical-illusions which evoke rotational movement (Figs. 6, 23).

Hallucinations of creeping line, depth, and shadow are caused by a loss of lateral or localized inhibition within cortical circuits.[3] The level of disinhibition and drift in the visual field is presumably proportional to the dose of hallucinogen, and this assumption is proved correct by individual reports of hallucinogen use. While at lower doses there may only be a slight wiggling or drifting to the rendering of line and depth, at higher doses the lines and colors between solid forms may appear to bend, swirl, or melt into one another.[4] The inability to alias smooth lines or hold sharp contrast between objects is the definition of linear destabilization.

The melting or drifting of textures seen on psychedelics originates in the layers of the visual cortex, but there are other similar inhibitory mechanisms which stabilize sensory cohesion across the entire brain. By applying disinhibition to audio networks, a subject under the influence of psychedelics may hear an echo or murmur rising in the wake of each sound. By applying disinhibition to tactile networks the subject might feel phantom fluid sensations rippling along the skin. These hallucination patterns are distinct in that they arise like a wiggling or fluid ripple in the wake of stimulus, causing a loss of sensory field stability similar to a slow dripping or melting of contrast boundaries.

Frame Destabilization and Frame Stacking

The seamless nature of human perception depends on the fast updating of sensory frame information. Humans update waking frame information at roughly the beta range of consciousness, around 12-30 Hz, which is why animation, film, TV, and computer screens all appear seamless in the 24-60 Hz range. Psychedelics destabilize smooth frame aliasing by interrupting pathways responsible for multisensory binding.[5] At low doses hallucinogenic interruption is felt as entopic hallucination, but at higher doses modulatory interruption leads to more extreme frame destabilization. Subjects under the influence of tryptamine hallucinogens report sensory frame lag and slow-motion frames; frame delay or echo; frame flange or recursive looping; frame stacking or frame freezing; frame rewind and fast forward; dropped frames; split or bifurcating frames; frame skipping; and similar nonlinear frame effects. These are all examples of extreme erratic hallucination linked to multisensory frame destabilization.

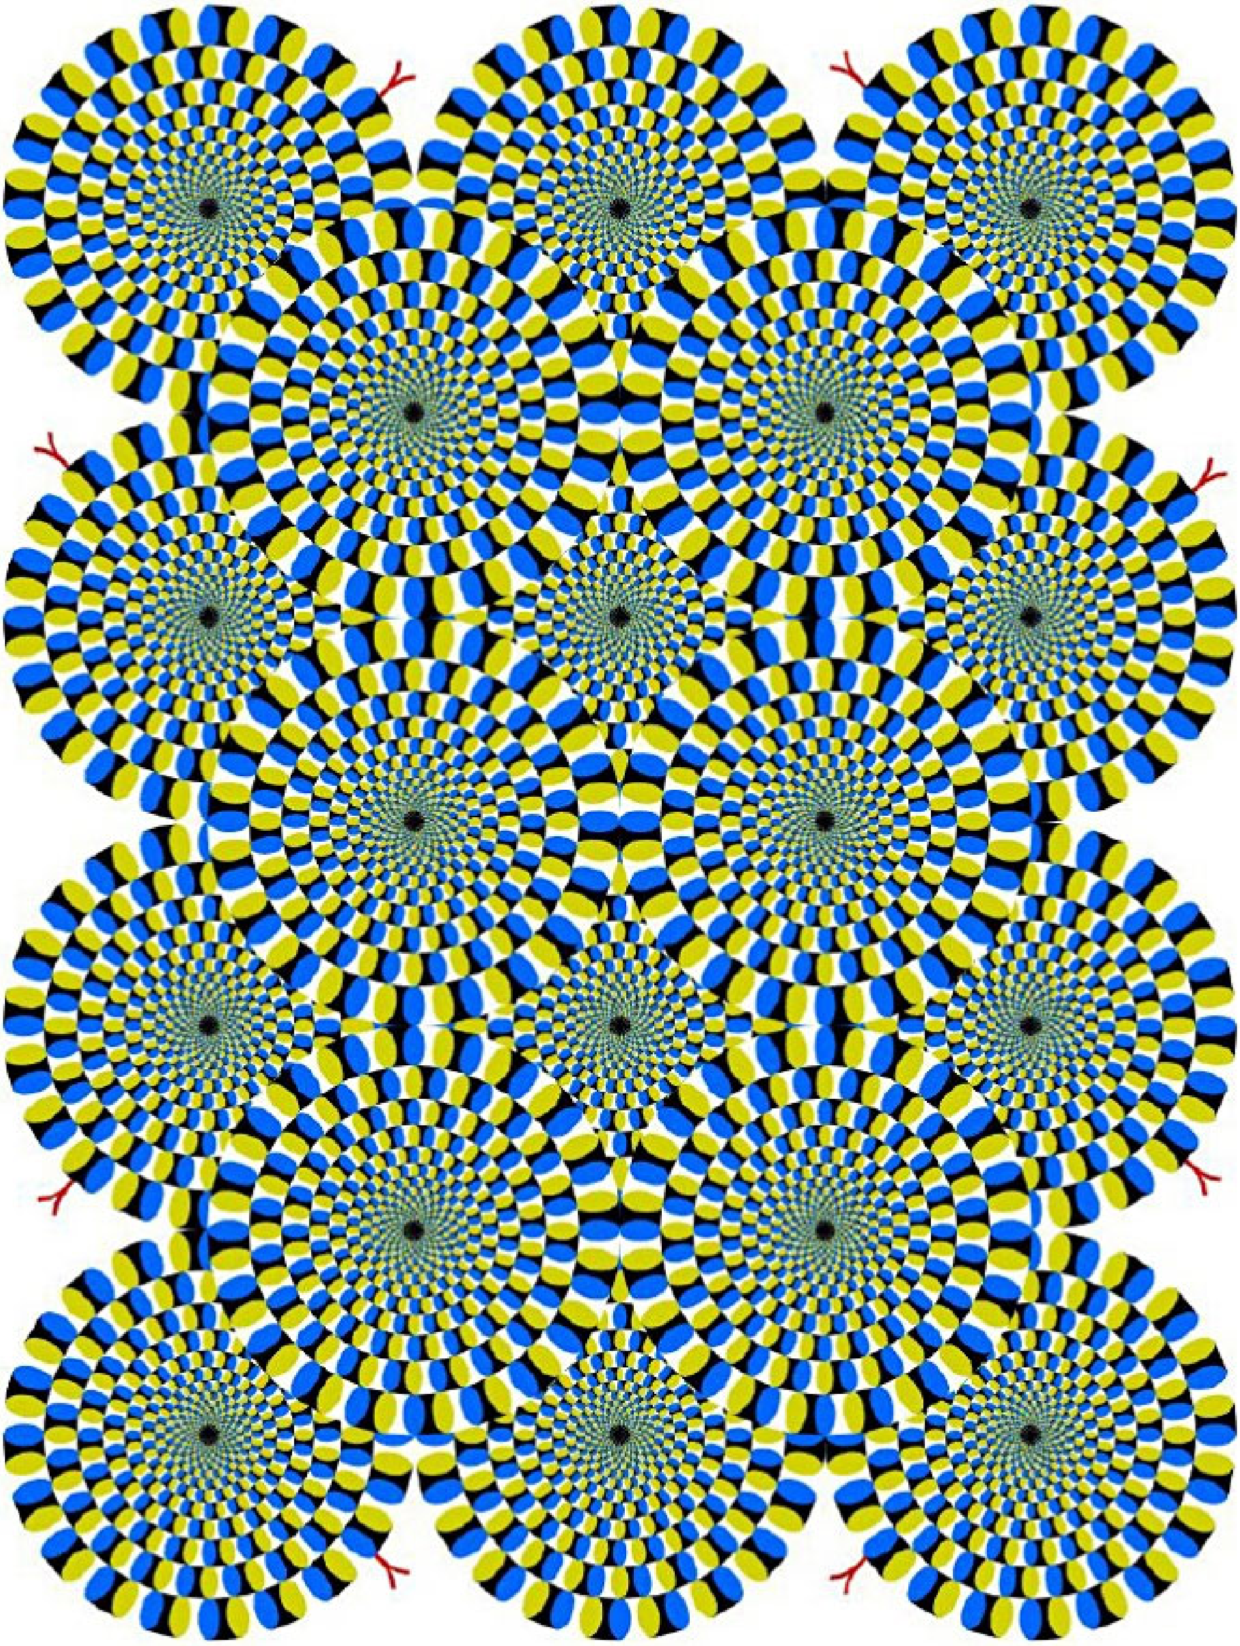

Figure 23. Akiyoshi Kitaoka's "Rotating Snakes" illusion. Stare at the center of any circle and the radial edges of nearby circles will appear to rotate. This image presents an example of the peripheral drift illusion due to contrast ambiguities in the visual field. This illusion exploits contrast expectations created by progressive 4-step gradients along radial tangents. The contrast expectations created by 4-step gradients are time-dependent and wired for motion detection in the periphery. The 4 degrees of color contrast around the periphery requires multiple frames to properly fill, creating a temporal ambiguity to edge aliasing exploited by this illusion. From Kitaoka, 2003.

To account for various types of hallucination related to multisensory frame destabilization the following hallucinogenic Frame Stacking Model has been proposed.[6] To create the perception of fluid movement from frame to frame, any frame we perceive must be a composite of at least two frames, one arising and one fading. Each frame is associated with a neural spike train involving some feedback to the thalamus and basal forebrain to fix the frame's snapshot in working memory. These feedback circuits normally neutralize in about 1/15th of a second, allowing for multisensory frame update of @15 Hz. If hallucinogens interrupt the process of frame neutralization for some small period of time, each frame then begins to fade more slowly until frame data stacks up and feeds back on incoming perception (Fig. 24). As recurrent information from multiple receding frames replicates and stacks onto incoming frames, each perceptual frame splits or bifurcates in complexity. This iterating pattern of recursive complexity is the formal description of a nonlinear system.

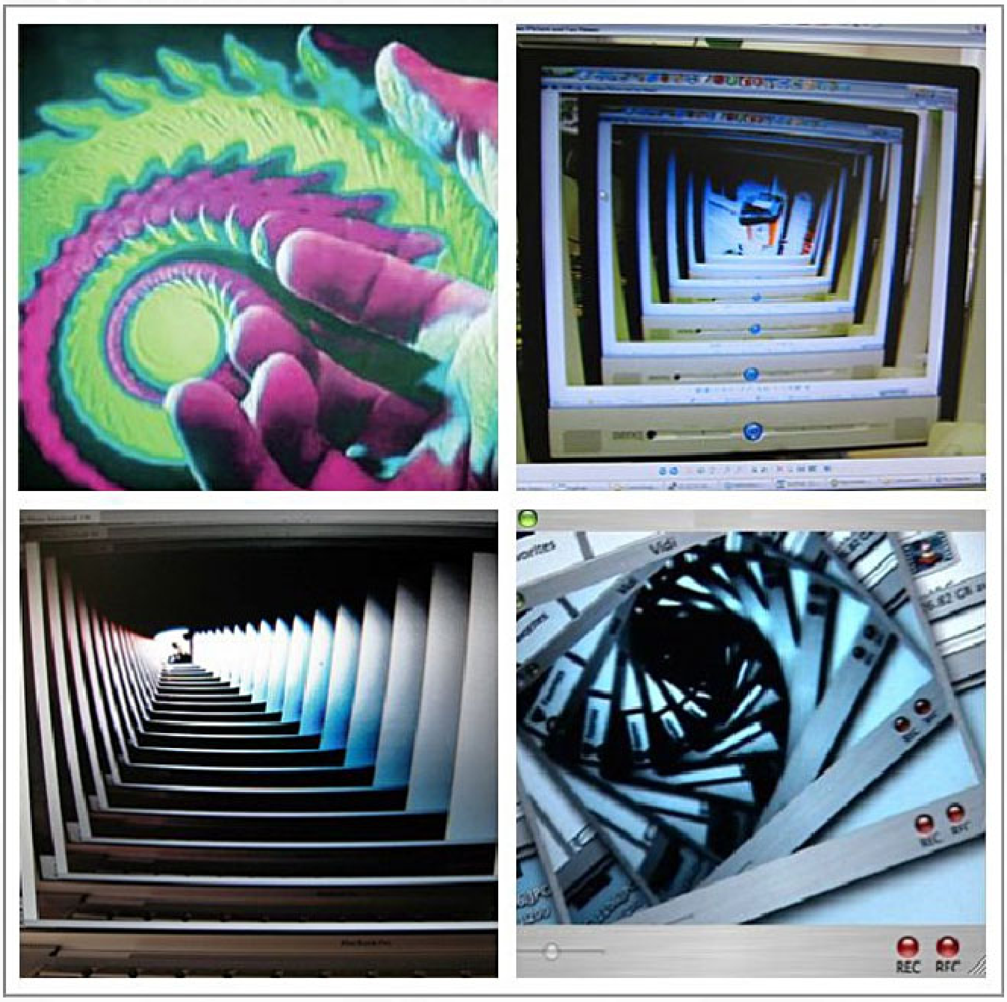

Figure 24. Examples of frame stacking caused by video feedback, which is isomorphic of fractal recursion, visual echo, and psychedelic hallucination. Frames stacked as few 16 layers deep quickly converge towards a vortex, a strange attractor, or a blur of infinite regression.

Frame stacking is considered to be progressive with hallucinogenic dose and grows from mild to extreme. At low doses you might have four frames stacked in perception instead of two; three fading and one arising. With three fading frames you may begin to see softening of edges or intensification of colors as the saturation of each frame stacks over the next. With eight frames stacked you might see visual artifacts like jitters or trails in the wake of any movement, similar to visual flange or video feedback. While holding the eyes still, an increase in frame overlay makes solid objects crystallize into something very fascinating and precious, like a faceted jewel, creating a quality of temporal depth and luminance to surfaces and textures. An increase in frame overlay also creates enhanced edge smoothing between solid objects, which gives reality a sensation of liquidity or stretchiness like surreal art, graffiti, or a cartoon. As frames regress the perspective of perceptual space may begin to elongate like a fish-eye lens. If a fading frame produces an emotionally salient pattern, the salient layer can then feed back into the arising frame as a progressively animated eidetic loop. When sixteen frames are stacked in perception, the wake of overlapping and receding content causes frame overload, confusion, disorientation, dropped frames, ego loss, bodily transcendence, and missing time. Beyond sixteen stacked frames the information density becomes too large for the human brain to render; ego consciousness is overwhelmed and totally destabilizes into a swirling vortex of timeless transpersonal unity.

The Frame Stacking Model presumes that hallucinogens enable a perceptual frame buffer that allows for sorting and browsing through multiple simultaneous linear frames; or that frame perception might be splintered into a radial kaleidoscope of multi-threaded parallel processing frames. Within the context of frame stacking, psychedelic consciousness may enable the subject to scroll back and forth in time; retrieve multiple simultaneous memories from a single stimulus; and project multiple versions of the self into multiple imaginary future scenarios. If the consciousness of a single person can be momentarily realized within three frames - the arising frame, the fading frame, and a static frame which holds the idealized concept of self - then the persistence of six or more frames could lead to the fabrication of two or more fully realized identities within a single subject. This frame splitting effect may explain how people can have conversations with phantom friends or relatives, or how a shaman might invoke anthropomorphized plant spirits with distinct personalities.

Multisensory Destabilization and Schizophrenia

In large doses, hallucinogens can produce multisensory destabilization; a state where sensations, objects, time, and space become entirely decoupled from each other in consciousness. The sensation of time uncoupling or of space losing it boundaries is difficult to describe as hallucination, but it is clearly hallucination. Loss of sensory or temporal frame cohesion implies multisensory destabilization and erratic hallucination. Externally the subject may be awake and responsive, but internally the brain has lost all state data and is completely disoriented, much like acute senility.[7] This state can be simultaneously hysterical or terrifying, which describes the extreme mood shifts associated with transient schizophrenia. Schizophrenia is linked to the inability to retain multisensory frame stability and decreased ability to produce the fast gamma oscillations needed to focus and bind sensory perception.[8,9] Multisensory destabilization is also reproduced by the hallucinogenic dissociatives ketamine and dextromethorphan (DXM) by blocking associative NMDA pathways necessary for fast sensory binding.[10]

Chapter 13

Psychedelic Neuroplasticity

Neural axons in the human brain are always branching and creating new synaptic connections to facilitate learning and development. Like the toning and bulking of muscle mass, neural connectivity, developmental growth, and plasticity are based partly on genetics and partly on the "use it or lose it" principle; the more you use a neural pathway the more robust and responsive it becomes, the less you use a pathway the weaker it becomes. Training and repetition build faster and more responsive connections; emotional attachments to concepts build more robust connections over time. The more a neuron or assembly of neurons is used in a specific exercise, the faster and more responsive those neurons will become when performing that task. This is how the brain learns new things and integrates new skills. Training, repetition, and reinforcement leads to long term changes in synaptic connectivity; these are the basics of neuroplasticity.[1]

Neuroplasticity is the physical mechanism which makes shamanism and psychedelic therapy viable. In dreaming, neuroplasticity is stimulated in response to daily routine and anxiety; in hypnosis neuroplasticity is stimulated in response to suggestion and reinforcement; in shamanism neuroplasticity is stimulated in response to dose, set, and setting. The efficacy of psychedelics in both shamanic transformation and clinical therapy relies on their unique ability to decouple the cortex, disassociate ego structures, and stimulate archetypal identity regression and personal transformation. No other class of drugs can claim to have such a radical effect on personality; radical personality change in response to brief psychedelic exposure implies neuroplasticity.

While there is no laboratory research to prove that psychedelics stimulate neuroplasticity, there is evidence that a single psychedelic session can produce long-term changes in personality.[2] People who take psychedelics sometimes adopt a new outlook on life, a new manner of dress, a new spirituality, perhaps even a new name to go with their new identity.[3] Self-reinvention is an integral part of psychedelic exploration and subculture. The forging of a new identity does not always happen in a single psychedelic session, but psychedelic experimentation can be a catalyst for sudden radical personality transformation. These basic observations make a case for psychedelics as facilitators of long term identity modification and neuroplasticity.

The Case for Psychedelic Neuroplasticity

Psychedelics can stimulate recall of lost memories and can also generate false memories; lost memory reconsolidation and false memory imprinting implies neuroplasticity. The brain builds tolerance to psychedelics quickly, but psychedelic tolerance can be surpassed by successively ingesting larger and larger doses.[4] Successive dosing and increasing levels of tolerance implies stress-based neuroplasticity. In the case of hallucinogen persisting perception disorder (HPPD), the subject retains some of the visual effects of hallucinogens long after the drug should have metabolized;[5] persisting reactions to neural stress imply neuroplasticity. Psychedelics have been used to facilitate cult induction and programming;[6] indoctrination implies identity-based neuroplasticity. Psychedelics induce peer and mate bonding in tribal subcultures; mate bonding implies identity-based neuroplasticity. Psychedelics can create positive long-term changes in mood and outlook;[2] long term outlook changes imply neuroplasticity. Finally, while lying in darkened silence, the psychedelic state resembles a deep dream-like trance; dreaming is known to facilitate memory compression and long-term memory potentiation (LTP).[7] Any drug which facilitates extended dream-like states should also facilitate memory compression, LTP, and neuroplasticity.

In programmatic terms, a psychedelic drug can be thought of as a back-door or reboot mechanism that allows the subject to enter a visually driven ego programming and debugging matrix; this state would be similar to hypnosis mixed with an element of lucid dreaming or creative visualization. To stretch the computer metaphor further, in the absence of hypnotic suggestion or shamanic control, the psychedelic debugging matrix will naturally drop into a maintenance mode where anxieties are brought to the fore like a screen-saver programmed to browse through repressed salient patterns arising within chaotic noise.[8] All of these programmatic metaphors for psychedelics are accurate, and all imply a spontaneous cataloging, compression, or re-organization of existing synaptic memory via nonlinear eidetic emotional cues; this implies synaptic testing and strengthening in response to pre-existing anxiety, which implies neuroplasticity.

Physiology of Psychedelic Neuroplasticity

Hallucinogens which target the 5-HT_{2A} receptor can influence cellular functioning via the activation of G-proteins and intracellular secondary messengers. The signaling pathways mediated by the 5-HT_{2A} receptor include the activation of PKC and MAPK, protein kinases which energize enzymes to perform complex cellular maintenance. The activation of PKC undoubtedly plays a role in the production and maintenance of long term memory. Evidence shows that inhibiting PKC activation in the cortex for as little as a few hours can cause the rapid erasure of long-term memory associations.[11] It is obvious that PKC is a fundamental part of memory formation and retention, and it is reasonable to assume that drugs which stimulate PKC activity may enhance or alter the processes of memory formation, recall, retention, and plasticity.

The process by which PKC mediates memory associations is still unknown, but the primary assumption is that PKC interacts with diglycerides (DAG) at the intracellular membrane to mark energetic signaling areas for receptor formation and synaptic strengthening. The secondary signaling cascade goes like this: The 5-HT_{2A} receptor is stimulated with an agonist, activating phospholipase C (PLC) in the cell membrane, which then chops a phospholipid (PIP_2 or PI) at the membrane into an IP_3 group and DAG. The DAG stays near the membrane while IP_3 activates the release of calcium (Ca^{2+}) from the endoplasmic reticulum, which then activates PKC, which allows PKC to carry energy back to the cell membrane near the DAG site before activating other enzymes and intracellular substrates. PKC performs its job by moving phosphate groups around the cytoplasm and activating cellular enzymes such as adenosine which forms AMP, ADP, and ATP by linking with phosphate groups in chains of up to three at once, allowing metabolic energy to move quickly to other sites throughout the cell. The addition and removal of phosphates to and from proteins is a fundamental part of all organic metabolic processes; 5-HT_{2A} agonists stimulate this phosphorylation process through PLC, IP_3, Ca^{2+}, and subsequent PKC activation.

The fact that 5-HT_{2A} agonists stimulate PKC and fundamental metabolic processes indicates a strong case for psychedelic neuroplasticity. It is interesting to note that Salvinorin A, from *Salvia divinorum*, also activates these same phosphorylation pathways through the G-coupled kappa-Opiod receptor.[12] It is also interesting to note that of all the hallucinogenic compounds that occur in nature, psilocybin (found in magic mushrooms) is the only one that comes with its own phosphate group (which is stripped to make psilocin), and also appears to be the weakest tryptamine agonist at the 5-HT_{2A} receptor.[13] While it is tempting to assert that PKC phosporylation is at the root of all hallucinogenesis and psychedelic effect, it has been demonstrated that 5-HT_{2A} mediated PI hydrolosis is not always a good indicator of psychedelic potency.[14] Although there are multiple factors responsible for hallucinogenesis, psychedelic stimulation of PKC activity undoubtedly plays a role in perturbing and stimulating persistent memory functions and promoting potential potent neuroplasticity.

Other research indicates that LSD activates cellular mechanisms to promote expression of genes responsible for encoding c-Fos and Arc proteins, particularly in the pre-frontal cortex (PFC).[15] c-Fos is essential to cell proliferation, differentiation, and cellular defense, while Arc (activity-regulated cytoskeleton-associated protein) regulates the formation and repair of the scaffolding maintaining neural shape and stability. By activating expression of c-Fos and Arc proteins in PFC neurons, LSD may promote potent neuroplasticity, cell proliferation, cell repair, and synaptic generation in neurons responsible for identity. Presumably any selective 5-HT_{2A} agonist will produce similar results, making hallucinogenic tryptamines primary candidates for cellular signal strengthening and profound identity-based neuroplasticity.

Positive and Negative Plasticity

Shamanic transformation may stimulate neuroplasticity by helping the subject realize a more transcendent or spiritually integrated vision of themselves. The logic follows that visualization of a transcendent inner self will reinforce positive personality traits and behavioral changes to synchronize with inner idealization. Shamanic identity transformation is not instantaneous, but instead follows an integrative process of synaptic testing and reinforcement over a period of days to weeks. Some psychedelic therapy stimulates neuroplasticity using techniques similar to the ten-step program employed by Alcoholics Anonymous (AA), where the subject takes a clinical inventory of their life and behaviors and assesses each area where they need forgive, accept, or make changes. In psychedelic therapy the process of uncovering and severing negative pathways is called catharsis; the process of wiring and reinforcing new pathways is called integration. These are examples of positive psychedelic plasticity used to maximize positive social integration. These processes are sometimes slow and require some small amount of mental discipline and behavioral follow-through for success.

There are many examples of negative psychedelic neuroplasticity. Renegade schools of ayahuasca sorcery and witchcraft employ some of the most elaborate and lethal mind-games ever devised, including the constant fear of attack by rival sorcerers through poisons, curses, dream invasion, and magical darts that may induce paralysis, cancer, death, or insanity.[9] The traditional shaman's constant stress of exposure to the effects of black magic mirrors paranoid psychosis and post-traumatic stress disorder; this implies negative plasticity. Exposing any subject to extended and repeated psychedelic sessions may force stress-driven plasticity associated with PTSD, torture, isolation, and sensory deprivation. Psychedelics may speed techniques of ego deprogramming and imprinting associated with brainwashing or cult indoctrination;[6] this implies mind control and negative neuroplasticity. Psychedelics may produce psychotic breaks where subjects become violent and deranged, or may reinforce delusional, messianic, paranoid, sociopathic, antisocial and megalomaniacal identity traits;[10] this also implies negative neuroplasticity. Thus, forging new synaptic pathways to radically alter identity structures is not always a good thing, this process can induce pathology as easily as it can reduce pathology.

Tribal Imprinting and Viral Neuroplasticity

One of the most interesting aspects of psychedelics is that group psychedelic experimentation can catalyze spontaneous organization of tribal subcultures and grassroots political movements. According to PIT, if you destabilize the top-down regulating influence of culture over a small group of peers, energetic tribal organizations will spontaneously emerge within those groups; this is an extrapolation of control theory and tenets of distributed cognition. Modern history has demonstrated that if you sprinkle LSD or psychedelic mushrooms over a major city, then flower children will blossom and form drum circles and begin to reproduce. But close observation of modern psychedelic subcultures reveals that radical identity reinvention is not a function of spiritual freedom or political subversion, but is more a viral form of tribal bonding and indoctrination. For example, the hippies of 1960s and the ravers of 1990s each preached freedom and individuality, yet each culture had strictly controlled tribal uniforms, politics, musical styles, and rituals, and ostracized outsiders as being squares or un-hip. This indicates that psychedelic tribal organization and identity reinvention is not a linear function of freedom of expression or social liberation, but is instead a nonlinear amplification of the typical motivators of social elitism, the fears of being ostracized, and the reinforcements of tribal acceptance; all of which strongly affect identity-based neuroplasticity. Presumably any tribe, cultural group, religion, cult, or government can employ psychedelic neuroplasticity to similar social organizing effect.

MERE PST.20
group presents
mushroom inside
BACK TO MUSHROOMS
SPECIAL GUEST FROM MOSCOW
TRANSDRIVER

Figure 25. Flyer for a 21st century mushroom trance party entitled, "Mushroom Inside: Back to Mushrooms," where a DJ inside a giant amanita mushroom controls a synchronized crowd of psilocybe-headed dancers through giant amplifiers made of psilocybin mushrooms. Like marionettes, the dancers assume archetypal forms of resonating Chladni patterns or fractal plane-filling curves in audio-motor synesthesia with the music. Note the ecological overtones as the grass, trees, and galaxy keep tempo with glowing approval.

The origins of shamanism are rooted in spirituality and myth, but the power of shamanism is entirely real. It is the goal of this text to explore rational limits and applications of shamanic power beyond the paradigms of mythology and faith healing. The subtitle of this text is "Shamanism in the Age of Reason," so it seems fitting to provide a good definition for shamanism. There are many definitions that have something to do with tribal healers, witch doctors, ritual plant magic, and/or dealing with the spirit world; these definitions conjure images of pre-industrial folk medicine steeped in superstition. Relegating shamanism to the bin of folk medicine fails to account for the sophistication of shamanic tradecraft, methodology, or the varying levels of shamanic manipulation. Traditional shamanism may be cloaked in the veil of superstition, but behind the veil is the real science of programming human belief and behavior with a blend of mysticism, ritual, and hallucinogenic drugs.

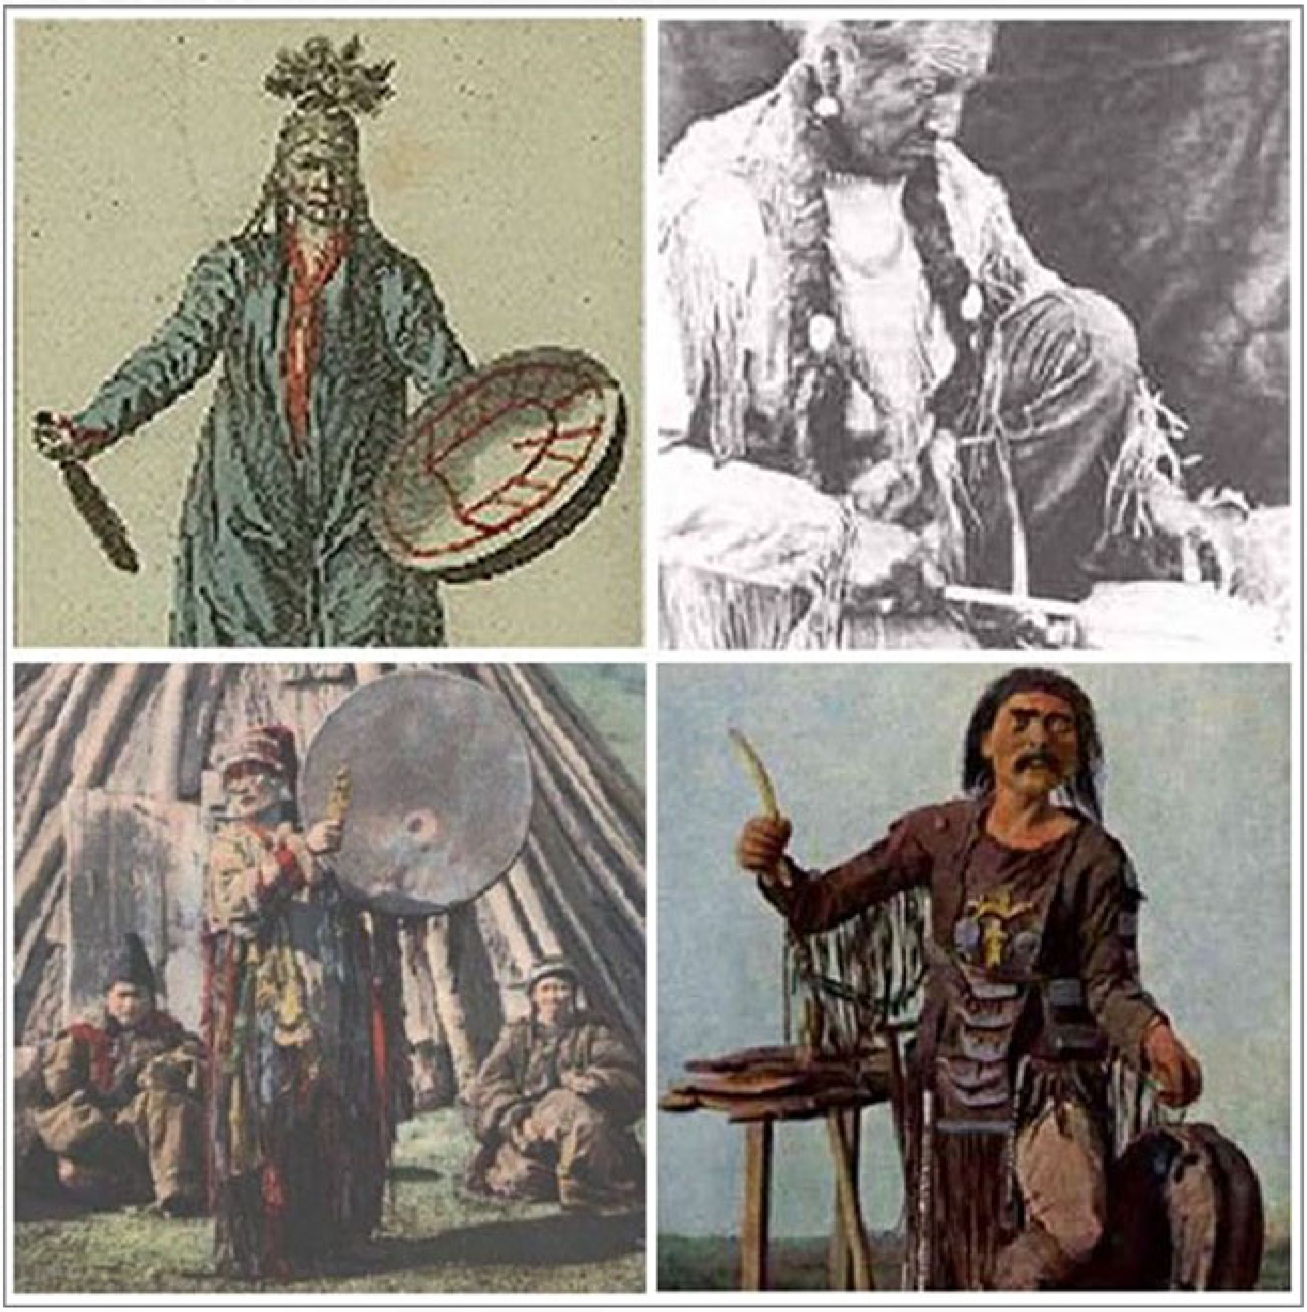

Figure 26. Pictures of the shaman from four different traditions. Clockwise from top: Tartar, Native American, Siberian, and Yakut. All shamen use medicine drums to control the tempo and amplitude of energy oscillating through the sacred circle.

Instead of focusing on the many societal roles and functions a shaman might fill, PIT takes a broader view and starts with this definition: Shamanism is the craft of evoking spontaneous organization of psychedelic information in a subject or group of subjects to promote plasticity, imprinting, and transformation. Psychedelic information implies holistic or meta level manipulation of memory and identity, and this definition fulfills the functions of therapy, sorcery, mind control, applied psychedelic science, targeted neuroplasticity, behavioral conditioning, and tribal bonding. The technology of evoking and imprinting psychedelic information is inherently neutral; the shaman learns to apply this technology for healing and positive plasticity, the sorcerer succumbs to the temptation to use this technology for black magic and negative plasticity.

Transformational Plasticity and Imprinting

The power of shamanism can be measured by the shamanic ability to transform subjective beliefs and behaviors. A shaman can transform the subject in the literal sense, through diet and chemical manipulation; or in the figurative sense, by altering the subject's paradigm and perception of reality. Both of these transformations imply targeted neuroplasticity. The extreme diets and psychedelic medicine catalyze spontaneous stress-based reorganization of neural identity structures, and the shamanic mythology creates the semantic frame through which the subject parses the transformational experience. Although psychedelics have been tested in brainwashing and hostile interrogation, the process of psychedelic imprinting usually works best if the subject is ready and willing to receive the transformation.[1]

Some aspects of psychedelic imprinting are automatic and spontaneously generated like dreams;[2] in this case the shaman's job is to apply the medicine and essentially look important doing nothing. In other instances the subject may have an adverse reaction to the medicine, or become lost in the psychedelic space; in this case the shaman may intervene with a spirit song, a meditative chant, or a rhythmic breathing exercise to guide the subject through the transition. In traditional or loosely organized shamanic ceremonies, the level of intervention and depth of psychedelic imprinting is controlled by ritual, shamanic intent, and group intuition; in clinical psychedelic therapy the depth of psychedelic imprinting is controlled by protocol.

Shamanic Reputation and Expectant Plasticity

If a shaman gains a reputation for being transformative, subjects will seek them out expecting to be transformed. Similarly, a popular shaman may become the target of a rival shaman seeking to curse them or bring them down with magic darts. Both scenarios indicate that the shaman has successfully imprinted his own supernatural abilities to the point of viral plasticity. A shaman does not need psychedelic drugs to accomplish this, any guru with a transformational philosophy and self-promotional streak can achieve this level of influence. The shaman differs from the New Age guru only by having mastery of the plants and the spirit world, which is rudimentary psychopharmacology and ritual transcendence. By offering his or her self as the path to sacred wisdom or healing, or by telling tales of supernatural battles with other sorcerers, the shaman implies that he or she is more powerful than the medicine they employ. Shamanic reputation builds subjective expectations, and in many ways is a very clever set-up and misdirection similar to priming a magic trick or a placebo. If the subject already believes the shaman has supernatural power, the task of transforming them with the medicine is the easy part.

By crafting a supernatural reputation, the shaman starts the process of bending the subject's beliefs and expectations long before the medicine is applied. In hostile interrogation and indoctrination techniques, this process of bending subjective beliefs is called "softening up" the subject, or priming neuroplasticity to be vulnerable to imprinting. If the subject does not appear to respect the shaman's supernatural authority, the shaman may become withholding and demand that the subject follow certain strange rules before applying the medicine. Establishing authority, submissiveness, and strictly enforced rules gives the shaman implicit control over the subject, and sets the stage for applying transformation. Even if the subject does not believe the shaman's mythology, by forcing the subject to follow ritual protocol the shaman establishes the power dynamic necessary for controlling the ceremony and imprinting the subject.

Shamanism, Chaos Magic, and Belief as Toolkit

The shaman's role will always be intertwined with the spiritual belief of the larger tribe or culture. The mythology is not important, a good shaman can adapt any mythology or belief to transformational ritual. Instead of preaching the mythology, the shaman exploits the mythology as a handle or tool for interfacing with and manipulating the subject's core identity structures. By adopting a mythology that's alluring to the patient, the shaman can apply identity transformation within a seamless spiritual context. The process of finding or seeding an emotional handle is a skill that can be learned, but it can also be purely intuitive. The technologies of religion, propaganda, agitprop, and social activism all use negative emotional handles to influence people's beliefs and behaviors; shamanism employs many of the same techniques with positive emotional handles. The practice of manipulating belief like a tool to produce transformative results has become popularly known as chaos magic.[3]

The bulk of available literature on shamanism focuses on sprits, spirit mythology, and the ways in which the shaman communes with plant and spirits to gain supernatural insights. The allure and power of a drug that allows the user to talk directly with spirits is obvious, but fascination with spirits and transcendence may also be a handle used by the shaman to manipulate and imprint a willing subject. Western spiritual seekers are quickly enamored with the romanticism of entheogenic spirit communion, this is not something a good shaman would overlook; this is something that can be easily exploited. Whether the subject comes looking for Jesus, God, plant spirits, healing, or transcendence, the spiritual passions of the subject are the most powerful items in the shaman's entire toolkit.

Shamanic Practice and Seeking Balance

The role of the shaman has always been to apply transformation, typically to restore balance and harmony within tribal units. The shaman works by organizing the flow of energy and information within individuals and tribal structures. The shaman synergizes many layers of transformation in the act of brewing and ingesting psychoactive sacraments, and uses mythology and sacred ritual to facilitate communication, navigate conflict, and fine-tune the overall health of the tribe. Since shamanic transformation can be used for both healing and sorcery, it is logical that the larger tribe will only tolerate such power as long as it is more therapeutic than destructive. Because of this dynamic, a practicing shaman may be inherently distrusted, and will always walk the line between outcast and savior. The romantic character of shamanism relies heavily on this outcast trope. If the shaman fails at the basic tasks of healing and conflict resolution, or abuses shamanic technology to undermine the well-being of the tribe for personal gain, then the shaman loses power and risks being ostracized by the tribe. Thus, the shaman's power is limited and ultimately defined by the trust placed in him by the larger tribe.

Chapter 15

An Overview of Physical Shamanism

Physical Shamanism, or Shamanism in the Age of Reason, is differentiated from Spiritual Shamanism in that physical shamanism relies on models of neural oscillators and resonant wave entrainment as opposed to spirit models of channeling, telepathy, or clairvoyance. The Control Interrupt Model presents a description of physical shamanism based on the precision coupling of a multisensory hallucinogenic interrupt to a resonant environmental driver.[1] Physical shamanism assumes the human brain in a destabilized state acts as a resonant oscillator, or a nonlinear information processing system; thus shamanism can be defined as the application of resonant drivers to mediate complex phase transitions between multi-stable states of consciousness.[10,11] The techniques of physical shamanism are often used in concert with a hallucinogen in order to entrance or hypnotize a subject or group of subjects into a targeted mystical state.

Spirit Voices, Shamanic Songs, and Strange Attractors

When a shaman takes a psychedelic he or she hears the spirit voices and intuitively learns to sing the spirit songs. These songs are taken directly from the shaman's head as the psychedelic begins to interrupt consciousness. In many ways these sacred songs, or *icaros*, are attempts to recreate the voice and tone of the pharmacological interaction at various stages of the psychedelic experience. The voice of the shamanic medicine is not human in the typical sense, the psychedelic voice is described more in terms of the repetitive bleeping and blooping of machine code; a biological thrumming; an electronic or alien pulsation; a guttural river of slurping and squelching sounds; the great wheeze of a mystical reed organ; the chirping of crickets; the croaking of frogs; or the fast-clicking communication of an insect intelligence.[2,3] All of these colorful metaphors are the same in that they perfectly describe a resonant standing wave in the alpha to gamma range driving amplitude along multisensory perceptual bands. As the hallucinogenic voice grows in strength, the resonance of the standing wave then couples with and drives the amplitude of all internal physiological processes.[4]

The Control Interrupt Model posits that these spirit voices are the nonlinear artifacts of the hallucinogenic interrupt frequency overlapping into multisensory frame perception with a specific ADSR (attack, decay, sustain, release) envelope. By modulating standing vocal waves, the shaman can exactly match the periodic frequency of the hallucinogenic interrupt; by changing the shape of the lips, the speed of air through the glottis, and the speed of the tongue flicking towards the back of the throat, the shaman can replicate the slippery shape and feel of the hallucinogen's interrupt envelope. Resonance is a term applied to oscillators when the shape and frequency of one standing wave harmonizes with and drives the amplitude, or energy, of another standing wave. By using the physical techniques of sound shaping and resonance, the shaman can amplify the hallucinogenic interrupt of any psychedelic and, beyond that, drive standing wave coherence among multiple participants in a shamanic ritual. This process is intuitive if the shaman merely pays close attention to his or her internal physiology as the hallucinogen takes action.

In the nomenclature of chaos theory, when a chaotic system evolves towards a particular state over time, that state is called an attractor, or a strange attractor in fractal systems. According to PIT, nonlinear consciousness is multi-stable, which means it can have many strange attractors pulling it towards many different stable states; or it can become stuck in a superposition or chaotic phase transition between two or more stable attractors. In normal perception, the primary attractor is linear consciousness; when consciousness is dramatically perturbed it will always find a way to return to the linear state after enough time, and consciousness tends to return to the linear state even when momentarily destabilized. In nonlinear consciousness the attractor may be a manic state, a trance state, a disoriented state, a paranoid state, an enlightened state, and so on. As psychedelic consciousness becomes complex and bifurcates, it gradually moves towards one of many multi-stable attractors, eventually locking into a complex stabilized state based on periodic drivers in set and setting. Once a subject under the influence of psychedelics finds an attractor state and locks into it, it becomes difficult to break the stabilizing harmonic pattern to move towards another attractor. Navigating between strange attractors in the destabilized nonlinear state is the primary function of shamanic singing and ritual; without the ability to self-navigate to a specific attractor, the subject may become stuck in a negative attractor, like an anxiety spiral or paranoid feedback loop.

Control Interrupt and Spirit Spaces

Mixing the Control Interrupt Model with traditional shamanic metaphors, it is accurate to say that the spirit world of each hallucinogen is literally erupting or interrupting into normal consciousness by carving out a distinct wave space where spirits can sneak packets of information to the subject in between normal frames. In physical terms, spirit information erupts into consciousness along the attack and decay of each psychedelic interrupt, then attenuates salient recognition and imprints itself into memory according to the receding sustain and release. As the interrupt's interference pattern overlaps onto multisensory perception, spirit information will appear to overlap onto the fabric of reality; bending towards the subject from a nearby dimension; trickling or gurgling over an invisible spillway; flickering in a stroboscopic film reel; parting through folds in a lattice or screen; becoming visible underneath a silken veil; and so on.[6] The subjective view of the spirit world is that it is an "invisible landscape" suddenly made visible to human eyes, and the addition of the hallucinogenic driver allows the veil of perception to be drawn open like shutters. These are all allusions to the boundaries of perceptual space changing as the hallucinogenic interrupt gains power, entrains sensory processing networks, and generates complex interference patterns.

To clarify this process with a metaphor, in the realm of shamanism it may be helpful to think of serotonergic (5-HT) modulation as reality, and the frequency of the hallucinogen as the spirit world. If serotonergic reality is modulated in the beta range at 12-30 Hz, and the hallucinogenic interrupt of tryptamine Y is modulated to 24 Hz, then there will be a predictable 24 Hz frame flicker superimposed over normal perception when you ingest hallucinogen Y. The interrupt frequency of 24 Hz presumes a very fast pulsation, fast enough to produce film-like or fully animated cartoon hallucinations. The 24 Hz spirit interrupt then masks itself onto multisensory pathways and is perceived as an ontologically distinct spirit realm emerging as a phantom but embedded part of physical reality. The physical intensity and tactile sensuality of the hallucinogenic spirit overlay will depend on the speed, shape, and intensity of the molecule's ADSR interrupt; higher doses of hallucinogen typically means harder attack, longer sustain, elongated release, and more seamless merging between reality and hallucination.

Driving Interrupt Amplitude and ADSR Transitions

As a psychedelic chemical is ingested and metabolized, the frequency and ADSR envelope of the hallucinogenic interrupt will transition over time. This shift in modulatory interrupt can be described as a change in interrupt amplitude over duration of effect; higher amplitude of interrupt means stronger and more realized hallucinations. A shaman will instinctively modulate the tones of his or her chants and songs to match the interrupt frequency and envelope of the hallucinogen as it begins to take effect. This technique accurately describes the oscillating drones, throat singing, slurping, sucking, squelching, whooshing, whistling, guttural ululating, and other vocalizations associated with ayahuasca shamanism.[2,3] If a shaman can drive interrupt amplitude through constructive vocal interference he or she should also be able to dampen interrupt amplitude through destructive vocal interference.[5] This technique would manifest as the ability to snap a subject out of an intense psychedelic experience with a quick change in phase between vocal waves and hallucinogenic interrupt frequency to decrease and flatten interrupt amplitude.

Techniques of using resonance to drive and shape wave amplitude have been exploited by modern DJs and music producers to engineer hard-attack bass lines associated with acid house and trance music. In the psychedelic musical genre known as Goa Trance, bass lines rip through crowds of thousands of dancers with the resonant wave shape and amplitude of electric saw blades. The intensely amplified resonant pulse drivers of Goa Trance music are, in fact, the current bleeding-edge ritual technology of physical shamanism. Goa Trance originated from India; Goa Trance DJs and producers are revered like gurus or techno-shamen; and fans of Goa Trance travel to global music festivals the way other spiritual adherents make yearly pilgrimages. Goa Trance music is the psychedelic essence of resonant hallucinogenic tryptamine interrupt expressing itself through modern ritual entrainment technology. Using an electrically amplified sound system, a trance DJ can manipulate a tribe of thousands in the same way a traditional shaman manipulates a tribe of dozens (Fig. 25). It is shamanic folk technology now applied on an industrial scale.

Cellular Automata and Fractal Imprinting

It may be difficult to understand how a simple periodic interrupt or modulatory frame pulse can create such dramatic perceptual results, but the hallucinogenic interrupt should be thought of as a linear resonant driver which, over time, generates complex and salient wave interference patterns. This can also be described by a dynamical information processing system generating complexity over time based on a simple repetitive algorithm, such as a fractal or a cellular automata. Fractals or cellular automata are perhaps the best visual metaphors for the spontaneous recursive organization of psychedelic visual hallucinations, and there is a very fractal or cellular element to the psychedelic experience which evolves along the flickering pulsation of the hallucinogen's interrupt. The endless unfolding of the infinite psychedelic fractal continues until the hallucinogen is metabolized, at which point the hallucinogenic interrupt wears off, fades away, and consciousness unwinds from the recursive spiral and stabilizes back into linear information processing.

Biology is repetitive feedback patterns; consciousness is repetitive feedback patterns; shamanism is the interruption and re-modulation of those repetitive feedback patterns to produce spectacular experiential results. In a very real way, shamanism is the art of shaping the fractal integrity of the individual from the genetic level up through personal memory and tribal identity. The hallucinogenic interrupt allows the shaman to break the subject's habituated daily routines and place them into a self-referential programming loop that includes all layers of personal and transpersonal identity. The interlocking facets of biological-self and transpersonal-self are made explicit in the flickering spirit space, and by controlling the depth of immersion into this space the shaman can control how much of the subject's existing identity is exposed, manipulated, and transformed in the process.

The fractal rendering of sub- and meta- consciousness in the shamanic space allows psychedelics to have a profound long-term effect on identity-based neuroplasticity.[9] By applying a resonant multisensory driver that acts as a fractal generator for archetypal symbols in imagination, the psychedelic paradigms imprinted into memory appear to be more cosmic, transpersonal, holographic, and durable than sum of linear identity constructs imprinted over the average lifespan. To be clear, the nonlinear iterative nature of psychedelic hallucination exploits archetypal symbol rendering to bypass linear ego and imprint a recursive, holographic view of the transcendent self within a larger emergent cosmic reality. This idealized, holographic representation of the self may be considered more "real" than the actual self, perhaps even experienced as the essential self, genetic self, transpersonal self, or the eternal soul. The ability to produce and manipulate a representation of the idealized transpersonal self makes psychedelics viable in shamanic transformation, clinical therapy, and spiritual awakening.

The holographic image of idealized self does not emerge in a single moment or even in a single psychedelic session; the organization of a psychedelic meta-identity is a process that may take many hours of a single psychedelic session or possibly multiple psychedelic sessions to fully complete. However, once the self-activation of psychedelic metaprogramming and holographic imprinting takes hold, the subject may perceive their transformation to be an evolutionary expression of a hidden genetic instruction set, or a more perfect and cosmically mature version of the self emerging through spiritual cleansing and rebirth.[7] There is evidence that a single psychedelic session can enhance self-worth and have lasting beneficial impact on mood and outlook.[8] There is also evidence that psychedelics can be used to imprint pathological, antisocial, and delusional identity constructs.[9] Holistic identity expression is generally considered to be a positive spiritual technology, but it can also be used to manipulate anxiety and exacerbate pathological behavior. This duality is commonly expressed in the nomenclature of therapy vs. mind control, negative vs. positive neuroplasticity, or shamanism vs. sorcery and witchcraft.

Linear vs. Nonlinear Memory Imprinting

The limits of human memory present some challenges for accurately encoding or describing the information generated in psychedelic states. Waking memory encodes linear, semantic information; dreams encode associative eidetic information; psychedelics encode nonlinear fractal information. There are many factors which limit the ability to accurately remember or recall psychedelic information. The rush of information is too fast; the content of the experience is too ineffable; and the processes of dreaming and eidetic visual hallucination blocks the formation of new semantic memories. In order to remember a dream a subject must wake up and make some mental notes, then go back to sleep to finish the dream; but if the subject does not rouse to some level of lucidity the dream is almost always forgotten. The same can be said for psychedelic hallucination; if the subject is too overwhelmed to make mental notes, the content totally bypasses linear semantic memory. However, if psychedelic hallucination employs the same spontaneous organization of eidetic information used to encode associative long-term memory through dreaming, then psychedelic fractal information may also imprint directly into long-term memory at a subconscious level.

Shamanic Information Compression

The functional limitations of human memory and expression have been problematic for high-dose psychedelic research from the beginning. The best writing, artwork, and video emulating the psychedelic experience must be created after the fact, sometimes painstakingly so. The visual reconstruction of psychedelic memory is a labor intensive process; a single subjective psychedelic frame may take weeks or months to visually render, and will still be lacking in context and complexity from the original experience. This is even more frustrating when you consider that a one line fractal algorithm or cellular automata can generate enough novel artistic complexity to keep the average human fascinated for hours. Linear approaches to capturing the psychedelic aesthetic almost always pale in comparison to their simpler, nonlinear generative counterparts.

The one artistic medium which can be expressed immediately in psychedelic intoxication without disrupting the quality of the shamanic experience is music. A shaman can relate the tone and content of the psychedelic experience in real time by singing, vocalizing, or playing drums (Fig. 26); this is the traditional method for binding psychedelic memory into physical space. The act of singing, drumming, or dancing also drives feedback and amplifies the energy of the psychedelic experience, thus making music the primary medium of psychedelic information compression and transmission.

There is compelling evidence that spontaneous singing and vocalization are forms of nonlinear psychedelic information compression. Glossolalia, or speaking in tongues, is reported as a spiritual side effect of psilocybin. Glossolalia may be considered a form of nonlinear speech, or psychedelic information erupting spontaneously through psycho-verbal synesthesia. When the shaman wants to speak with the spirit voice, that voice comes out more like music or glossolalia than like words and grammar. When a subject on psychedelics listens to music, the music expands from auditory signal into full multisensory synesthesia; every layer of emotional resonance in the song is laid bare for the subject to intimately see and feel. Claiming that psychedelics make music sound better or allow you to "see the music" is easy; this appreciation has fueled global music festivals and DJ circuits for decades. Shamanic music does not need to store visual information because under the influence of psychedelics the music naturally expands into visual perception. A sacred song from a rainforest shaman may not induce a strong reaction in a sober subject, but under the influence of ayahuasca that same song may open a window into the shaman's spirit world. This phenomena goes beyond the level of mere music appreciation, it demonstrates a cross-cultural technology for real-time encoding and transmission of nonlinear psychedelic information.

By examining the wave properties of ayahuasca *icaros*, is it possible to construct an experiential rendering of the synesthetic hallucinogenic effects. A shaman may make gurgling or retching noises to amplify modulatory interruption of 5-HT receptors in the gut to drive purgation. A fast rustling or shushing noise, like a snake rattle or wind through tree branches, evokes alpha-range relaxation and mental fluidity, and may also create goose-bumps and a salient sense of supernatural mystery. A droning drum beat or chant drives theta-band trance and hypnagogic states. A whistling or high pitched melody drives beta and gamma coherence, creating sharp multisensory synesthesia of rising eidetic images. A guttural croaking or a resonant bass line amplifies the saturated attack and decay of stacking hallucinogenic frames.

A shaman may employ one or all of these techniques at various stages of ceremony, and may use them repetitively or cyclically, like a winding stem that moves through deeper and deeper layers of hallucinogenic immersion. The shamanic technique of lulling and evoking mystical hallucination can be compared to the frenetic qualities of modern trance music, where the goal is to entrain and sustain a high-energy visual state that unfolds and recourses for extended periods of time. Trance songs are built around arpeggiated looping melodies which grow in complexity over time, culminating in phase transitions, or breakdowns, where stable looping states are shattered into chaos. While trance dancing, these breakdowns are felt as euphoric, like shattering a barrier into a higher state of freedom and bliss, and when the chaos of the breakdown converges back towards a rhythm, it is an even more frenetic level of organized syncopated beats driven and held together by deep resonant bass pulses. The wave analysis of both modern trance music and traditional *icaros* indicates that these are not merely forms of artistic expression, but are also formal technologies for mediating and navigating various levels of stability in chaotic psychedelic hallucination.

Chapter 16

Physical Shamanism and Shamanic Therapy

The practice of spiritual shamanism and healing has been covered in many texts, so here we will examine physical models of shamanic therapy only as they apply directly to Psychedelic Information Theory (PIT). According to PIT, hallucination is the spontaneous production of nonlinear information via destabilization of multisensory perception.[1] Similarly, shamanic therapy is the production of spontaneous cellular organization via destabilization of metabolic homeostasis. An M.D. may prescribe a specific therapy to treat a specific symptom or pathology; a shaman will look beyond the pathology and prescribe radical dieting and psychedelic drug therapy to fully reboot, re-tune, and recycle the patient's entire metabolic process. Shamanic therapy can be considered a nonlinear or holistic approach to diagnosis and healing.

Modern Shamanic Psychotherapy

In modern clinical therapy psychedelics are employed to improve psychological resilience in the face of stress or trauma, typically in the case of depression, PTSD, and anxiety. Psychedelics are thought to produce psychological resilience through the spontaneous creation of autobiographical insights and transpersonal spiritual epiphanies which compress existing memories into a new holistic identity. According to PIT, the generation of salient insights in psychedelic trance is the byproduct of nonlinear information creation and memory compression, just as dreaming is a form of associative information creation and compression.[2] Even a single low-dose psychedelic session can produce changes in identity and transpersonal awareness that last a lifetime.[3,4,5]

To apply simple psychedelic therapy, the shaman need do nothing more than provide the medicine and a warm quiet place for the subject to lie down. Psychological resilience is generated by allowing the subject to navigate anxieties, forgive and accept past behaviors, and sense a transpersonal unity and love flowing through all creation. This method works best in targeted therapy, and should only be applied in a controlled setting to reduce anxiety spirals and negative plasticity.

Shamanic Dieting, Purging, and Cleansing

Traditional shamanic therapy typically includes components of restrictive dieting, fasting, and purgation of bodily wastes and fluids.[6] The common wisdom is that dieting and purgation cleanses and purifies the body, restoring it to harmony and balance. A more cynical analysis concludes that radical dieting and fasting destabilizes the body's metabolic homeostasis and puts it into deprived states of heightened alertness and stress, states which can easily produce psychosis if prolonged for a day or more. Subjective reports of psychedelic use often include an initial period of stomach pain and intestinal discomfort preceding full psychedelic destabilization; this is because the psychedelic must interrupt 5-HT receptors in the gut before metabolic homeostasis can be fully uncoupled and re-tuned. Techniques of dieting and fasting speed and amplify the destabilizing effect of psychedelics on global metabolic homeostasis.

Metabolic Destabilization and Cellular Regeneration

The Control Interrupt Model posits that hallucinogens produce complex perceptual results through pharmacological interference of multisensory frame stability.[1] The same model applied to neural oscillators in a sensory network can be applied to cellular oscillators in an biological matrix. Many functions of metabolism and cellular signaling are modulated by 5-HT and dopamine; interrupting these signaling pathways will not only produce patterns of spontaneous neural organization, they will also produce patterns of spontaneous metabolic and cellular organization. For instance, 5-HT_{2A} receptors and serotonin have been shown to play a large role in mediating blood platelet aggregation.[10] Hallucinogens target 5-HT_{2A} receptors, and platelet aggregation is a fundamental immune mechanism. 5-HT_{2A} activation has also been demonstrated to produce powerful anti-inflammatory effects in cardiovascular and soft tissues; and 5-HT_{2A} agonists like LSD may produce potent anti-inflammatory effects against TNF-a (tumor necrosis factor alpha), an autoimmune regulator which has been indicated in atherosclerosis, rheumatoid arthritis, psoriasis, type II diabetes, depression, schizophrenia, and Alzheimer's disease.[11]

Because the 5-HT$_{2A}$ receptor is a G-coupled protein that promotes secondary transmission within the cell membrane, psychedelics that target the 5-HT$_{2A}$ receptor can influence a wide variety of intracellular functions. The signaling pathways mediated by the 5-HT$_{2A}$ receptor include the release of charged calcium ions (Ca^{2+}) and the activation of PKC and MAPK, protein kinases which transfer energy to proteins and enzymes that regulate cellular metabolism and proliferation. Coaxing cellular signaling pathways into patterns of spontaneous regeneration, anti-inflammatory, or autoimmune organization is at the root of all physical shamanic therapy. This model can be applied to neural inflammation, as in cluster headaches; emotional inflammation, as in PTSD; stress-related soft-tissue inflammation, as in fibromyalgia; or any systemic inflammation related to stress, chronic disease, and autoimmune disorders.

Subjects under the influence of psychedelics sometimes report feelings of being cleansed from the inside, like each cell is being polished and organized, and that waste and cellular debris are being expelled. This sensation has been compared to a radical auto-immune response, like computerized maintenance routine for de-fragmenting and optimizing cellular memory structures. Just as neural assemblies may be coaxed into becoming spontaneous nonlinear feedback generators, cellular signaling pathways may be coaxed into generating information via spontaneous energetic metabolic pathway testing, strengthening, and regeneration. Just as nonlinear hallucination may facilitate memory potentiation in the same way as dreaming, nonlinear metabolic organization may facilitate cellular regeneration or immunological response similar to states of fever or deep restorative sleep. The cellular regenerative power of psychedelics have only recently been demonstrated in scientific terms, but in shamanic models this restorative function is taken for granted.

Physical Shamanism and Metabolic Entrainment

Physical shamanism employs wave-based entrainment techniques to coax spontaneous nonlinear organization in metabolic pathways and cellular signaling systems. Typical shamanic wave entrainment comes in the form of singing or music, but can also be applied through talk, touch, hypnotic motion, or other repetitive sensory feedback stimulation. Entraining a subject into a targeted state of consciousness is the science of hypnosis or trance. The psychedelic medicine allows the patient's homeostasis to become destabilized, and in this state the shaman becomes the circuit driver or entrainer, the oscillator with the most power to alter frequencies and amplify or dampen signal strength across the entire circuit. Acting as a hypnotic entrainer, the shaman can place the patient into dream-like trance and then synchronize his own perception to the patient's subtle internal body rhythms. The shaman uses the hallucinogenic interrupt as a control frequency for mediating contact with and manipulating the patient's metabolic processes. Once the control frequency connection has been established through mutual ingestion of the psychedelic medicine, the shaman then uses specialized entrainment waves to coax new metabolic interference patterns and signaling pathways throughout the patient's cellular matrix.

In Shipibo ayahuasca shamanism, the shaman takes the psychedelic medicine in order to visualize a flickering grid of patterns and symbols crawling across the surface of the patient. These ayahuasca patterns are embedded into Shipibo textiles (Fig. 27), ceramics, tattoos, and all forms of tribal artwork, and are considered to be visual representations of the *icaros* sung during shamanic ceremony. Each Shipibo pattern corresponds to a sacred psychedelic space where a specific type of information is manipulated and revealed, and by tuning the fluctuation of these patterns through the patient's biological systems, the shaman can sense blocked signaling pathways, restore atrophied pathways, and bring harmony and balance to the organism. Subjects under the influence of ayahuasca and shamanic singing often report the feeling of every cell in their body resonating in harmony with the healing songs of the *Maestro*.[7,8]

The ayahuasca shaman may employ hands-on techniques to massage the patient's energy patterns into a more harmonic shape, sometimes even sucking or blowing psychic energy through the patient, or perhaps performing a psychic surgery to remove a dark body, a block, or a curse.[9] Sometimes the shaman must dig very deep into muscle and organ tissue before the source of illness can be found; sometimes the patient's energy pathways are so blocked or degraded they are impossible to fix. The shaman may use high-pitched vocal tones to focus sound waves deep into the body, hoping to break apart blocked signal pathways via the power of resonant intonation. The shaman may use high pitched whining or whistling tones focused at one area of the body, or may use throat singing to invoke deep rumbling bass tones which make the patient's chest cavity resonate at same frequency as sound vibrations moving deep into the Earth.[7]

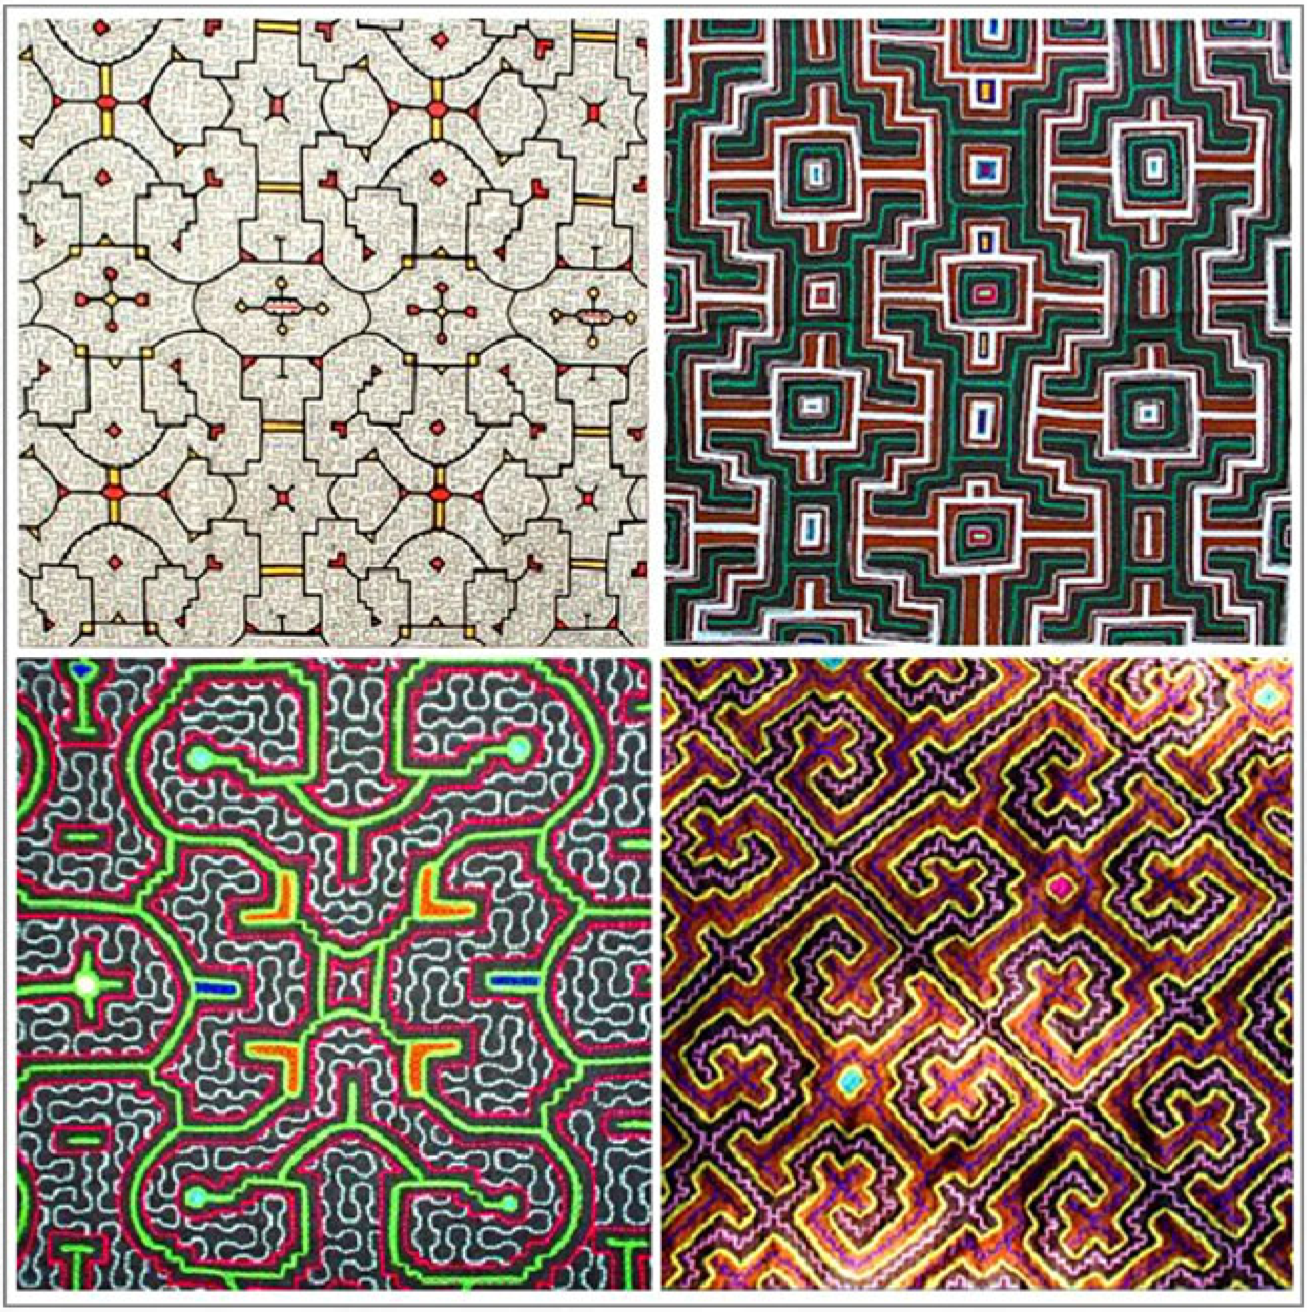

Figure 27. Patterns from Shipibo textiles are nonlinear artifacts of ayahuasca hallucination, and are also isomorphic of Chladni resonating interference patterns and Peano plane-filling fractal curves.

The case can be made that Shipibo textile patterns and sacred songs are compressed artifacts of nonlinear hallucination. These patterns are isomorphic of Chladni resonating interference patterns (Fig. 31), as well as Peano space-filling fractal curves (Fig. 28), S- or L-shaped patterns which repeat in embedded granularity depending on the depth of system iteration.[12] Shipibo textile patterns correspond to specific resonating tones and states of consciousness, and *icaros* are cultural technologies for accessing specific states of highly organized nonlinear feedback complexity in both neural and cellular signaling pathways. By employing these techniques under the influence of psychedelics, the shaman can entrain the biological functions of the patient all the way down to the cellular level, perhaps even to the genetic level. Transitioning through these levels would depend on the granular complexity of the interference pattern, or depth of system iteration, created between the shamanic entrainment wave and the hallucinogenic interrupt.

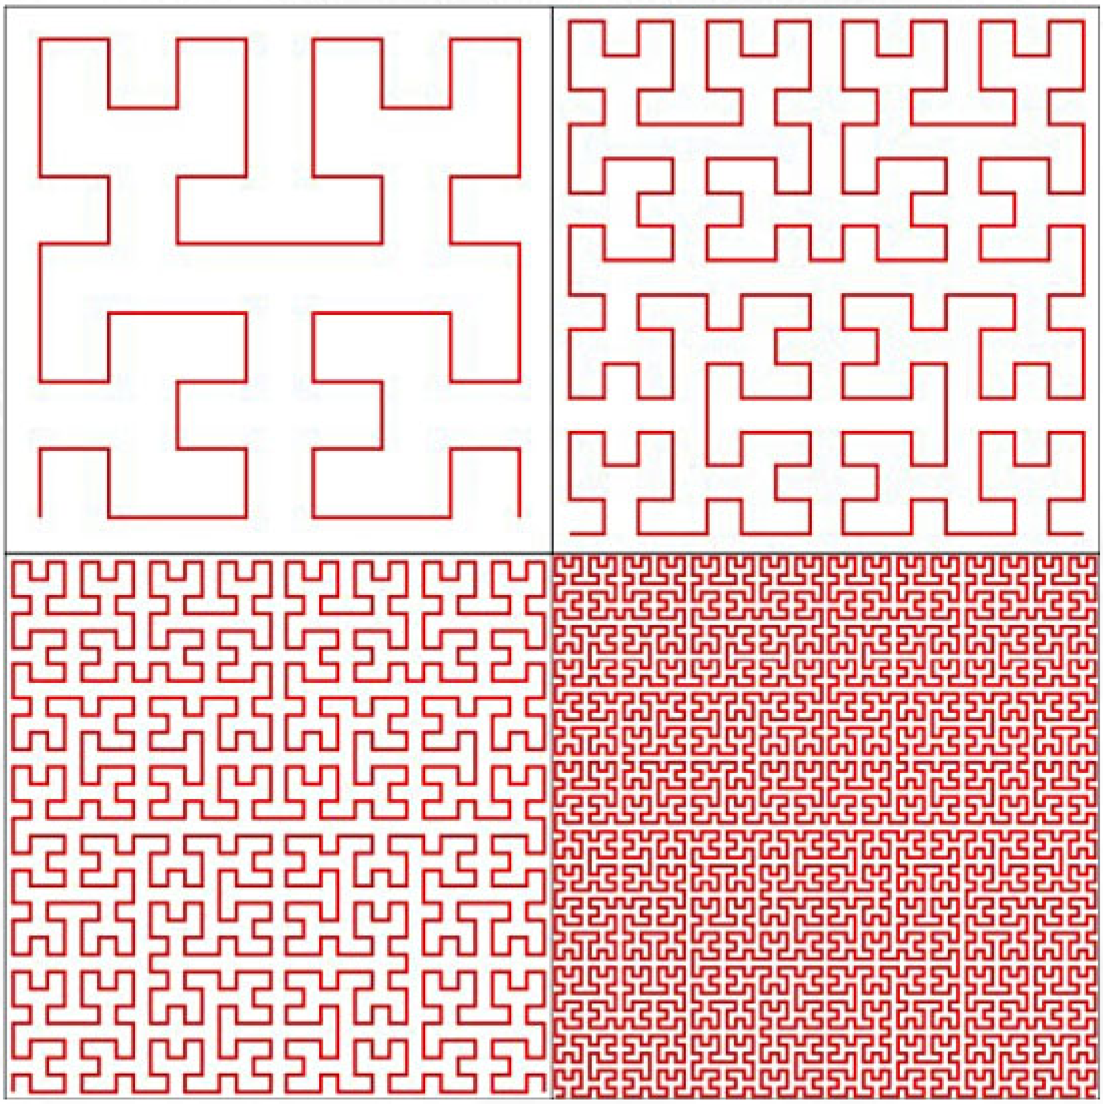

Figure 28. Hilbert curves are examples of recursively constructed L-shaped Peano curves, also called space-filling or plane-filling curves, which recede in granularity with each octave or iteration. From Wolfram Math, 2010.

Chapter 17

Hypnotic Entrainment and Induced Trance States

The fundamentals of hypnosis and induced trance states begin with the concepts of wave resonance and entrainment. Resonance is the quality of any oscillating system (waves in a neural network) to reach maximum amplitude (power) when stimulated with periodic drivers (pulses) at a specific pitch or rhythm (a resonant frequency). Oscillators can have many resonant frequencies which top out at maximum amplitudes. If we envision the brain as an oscillator for maintaining stable bands of consciousness, each band in the spectrum must therefore have its own corresponding resonant frequency, or frequencies, which can drive spontaneous phase transitions into that standing wave state. The process of using resonance to drive the frequency and amplitude of oscillators is called entrainment, and when the shaman induces a trance state he is applying resonant wave interference to entrain the frequency of the patient's neural oscillators.

Neural Oscillators

All states of consciousness are created by the act of neurons firing in a network. When a single neuron fires once it is not a big event, but when a neuron fires in a rapid sequence then it is signaling other neurons with a fine vibration of wave spikes; these neural spikes are the language of consciousness. When two or more neurons fire at the same frequency they are said to be synchronized, and when two areas of the brain are firing in synchrony there is said to be coherence between these areas, which means they are most likely engaged in a complex distributed processing task. When neurons are coupled together in a recurrent network, the rapid pulses sent back and forth between them are referred to as oscillations, and these oscillations take on the predictable mathematical properties of waves; a wave being any standing oscillation passing through a medium. These standing oscillations - literal waves of energy rippling through pathways in the cranial saltwater - are the field effect of consciousness flowing through the neural network. Smooth or harmonic propagation of these waves indicates high fidelity and stability in the field of consciousness; erratic propagation or interference in these waves indicates a chaotic, transitional, or destabilized field of consciousness.

EEG and Brainwaves

The wave-like oscillations of the brain can be measured via electroencephalography (EEG), a technique in which electrodes are placed on the skin and scalp to aggregate the voltage of energy waves produced along the outermost cortical layers of the brain. EEG machines produce graphs of brain activity over time, and each state of consciousness occupies its own distinct space along the brain wave spectrum (Fig. 29). The normal waking consciousness we perceive as active self is a beta state which begins around 12 Hz, or 12 cycles-persecond; this is the speed at which consciousness updates in a focused, active state. In highly focused or intense waking states these beta rhythms can be pushed up to around 38 Hz, which means the neural network would be cycling information at a rate of thirty-eight framesper-second (FPS).

Below beta is the alpha state, in the 7-12 Hz range, which is associated with detached critical analysis and more relaxed physical intuition. Even more relaxed than alpha is the theta state between 4-7 Hz; this band makes up the transitional states between waking and sleeping, including meditative and lucid dream states. The waking mind finally shuts down at the delta range of 0.5 to 4 Hz, where the brain slows into the deep rhythms of regenerative sleep. The brain wave spectrum from 0.5 to 38 Hz is where we spend all of our days every day, with global brain cohesion rarely tipping over into the high gamma range of 40 Hz and beyond, bands associated with fast personal awareness and highly focused connective insight. But even higher than gamma is the hypergamma range, which is over 100 Hz; and above that is the mythical lambda state, over 200 Hz, where it is rumored that human consciousness tops out at total awareness of all things from the beginning of time to the end of history. On the other end, even lower than deep delta sleep, is the mythical epsilon state where brain waves drop below 0.5 Hz and a yogic state of suspended animation occurs.

When evaluating brainwaves, human consciousness appears to be like a musical instrument than can be tuned and tweaked along a predictable spectrum of possible tones and chords. The brain wave spectrum as detailed here is only the most basic information, but EEG and brain wave science is rich with detail on how the various states interact with one another. For instance, there is evidence that slow wave oscillators in the brainstem may act as the circadian drumbeat of all consciousness; that fast gamma waves are employed spontaneously to bind coherence between slower brain areas; that slow epsilon waves may drive amplitude in the hypergamma and lambda ranges; that the mu rhythm (8-12 Hz) controls and interprets contralateral motor activation; that there are specific brain organs and hormones responsible for attenuating specific pulse ranges and keeping the brain in synch; that beta states promote anxiety; that the brain constantly produces many simultaneous bands of activity at differing power ranges in any state of consciousness; and so on. Brainwaves are often fleeting, irregular, and disorganized; consciousness is distributed and constantly transitioning between multiple tasks and states of focus.

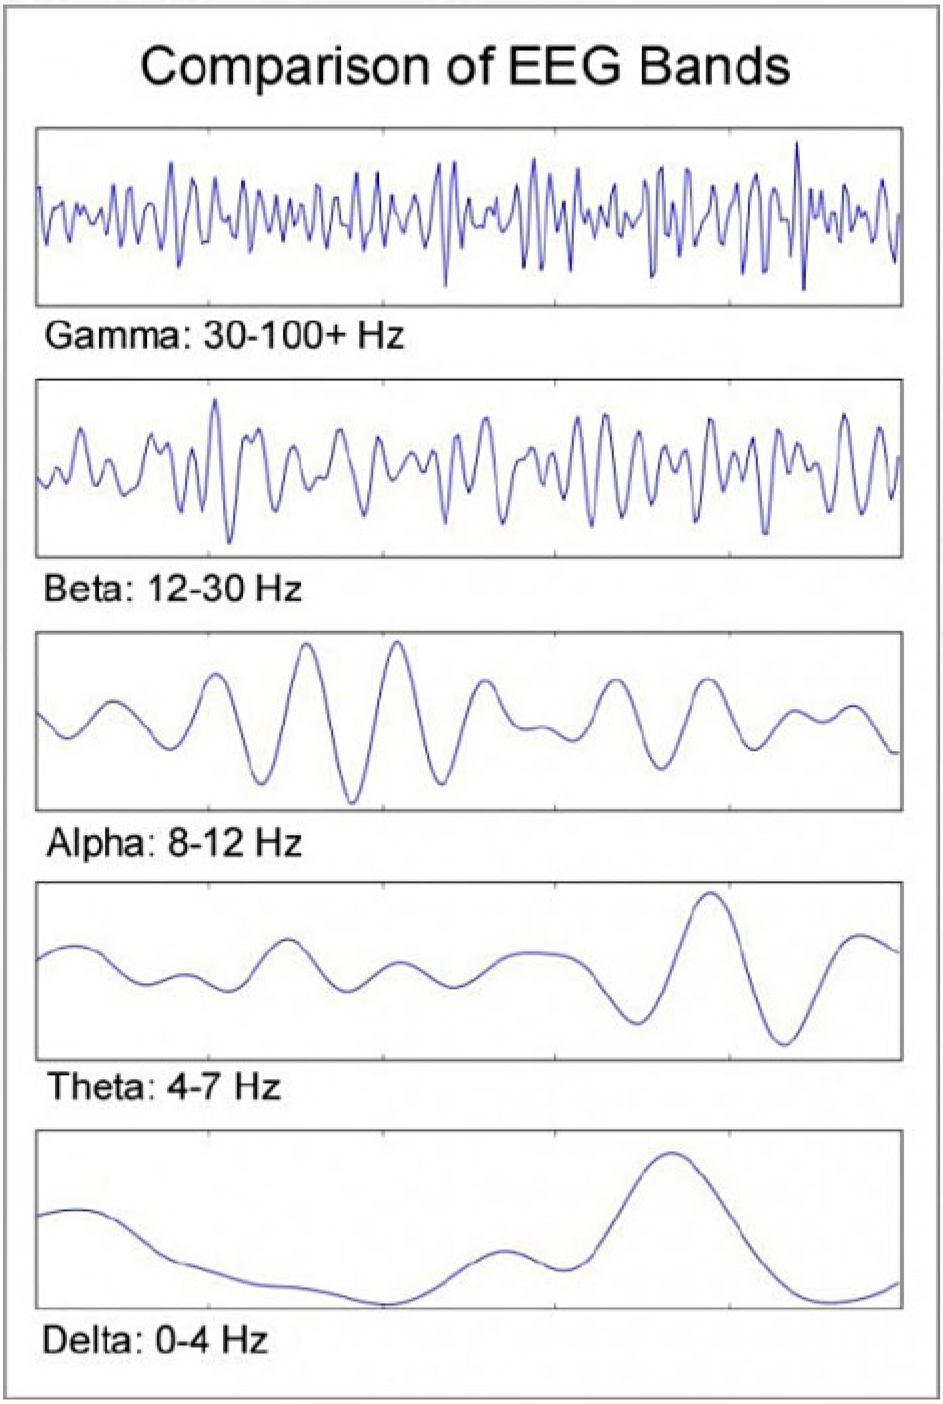

Figure 29. EEG bands over one second of activity. From WikiPedia.

Hypnosis, Induced Trance States, and Entrainment

Most shamanic work is done in what is known as a trance state; a highly relaxed state of extremely narrowed focus. The traditional shamanic trance state is in the theta range, around 4-7 Hz, which is a meditative state in the boundary zone between sleeping and waking. Most shamanic drum circles drop naturally into the theta range, and this is the same range a hypnotherapist will drop a patient into when inducing a highly relaxed state. This range is also associated with daydreaming, memory recall, and guided visualization. The high end of the theta band is associated with internal focus, visualization, and sustained concentration; the lower end is associated with more transient states of daydream, spontaneous memory recall, and lucid dreaming. Somewhere in the lower end of this zone is the hypnagogic grey area between waking and sleeping where body-consciousness disappears and the user feels floating sensations and may have out-of-body experiences (OBEs).

One of the ways a shaman achieves a trance state is through hypnosis. A typical hypnotherapy routine will guide the patient slowly down through a relaxed alpha state and gently place them right on the borderline of the hypnagogic theta state. With the patient teetering on the edge of hypnagogia, the therapist can then either engage them casually in a minimally aware alpha state or tip them into an internal theta state where it is easier to imprint new suggestions onto existing memory structures. If the hypnotherapist wants to make a strong imprint, he will introduce a suggestion in a receptive alpha state, then drop the patient into a low theta state to process the suggestion, then bring them back up to alpha to reinforce the suggestion, and then finally send them back down to low theta or slow delta sleep for further deep associative imprinting. This basic hypnotic routine is meant to focus the patient into the disengaged trance where rational override is shut down and the brain is vulnerable to suggestive memory imprinting. Most modern hypnotherapy focuses on behavioral imprinting, but the hypnotherapist may also uncover lost memories, imprint new memories, suggest the patient is floating, or take the patient on a guided visualization through a dream world. While performing trance work the shaman will tell the patient to remain completely still; this is to minimize circuit perturbation and wave interference produced by voluntary motor rhythms.

Shamanic Entrainment Technology

Hypnotherapy contains many of the same elements of shamanism, but hypnotherapy does not work for everyone. In shamanic therapy the psychedelic agent is applied to destabilize top-down control and make the patient more susceptible to entrainment for longer periods of time. If the patient is lying down with their eyes closed then psychedelics will produce a trance state fairly reliably on their own; the shaman does not need to do much more than measure an accurate dose and provide a safe place for quiet reflection. But aside from treating patients, the shaman also leads group bonding rituals, and these group rituals all utilize similar hypnotic entrainment technologies.

Typical shamanic entrainment technology may include drums, chants, music, strobe lights, chimes, audio pulses, and talk routines which guide the ritual participants into a shared trance. Native American peyote rituals use the beat of a medicine drum as the synchronous driver for the baseline trance, and then layer the rhythm with vocal drones to create resonant drivers which maximize brain wave amplitude and global coherence in the group circuit. Discussion of periodic resonant oscillators and entrainment is essentially a physics-based deconstruction of music's power to induce and lock targeted mind states, which is something we all instinctively understand from the experience of listening to music. However, when you look at this dynamic from a physical standpoint, when the mind is entranced by an entrainment technology such as music, the mind and the music merge from separate individual oscillators into a standing harmonic interference pattern with its own unique properties of coherence and stability.

In traditional Amazonian ayahuasca ceremonies, the shaman may be blessed with an *icaro*, or a sacred song which is delivered spontaneously into the brain by the spirits. When the shaman sings this sacred song, the ritual participants are quickly ushered into the sacred space along with the shaman. Using the entrainment dynamic it is reasonable to assume to that these *icaros* are feedback vocalizations tuned to the resonant frequency of the specific trance state occupied by the shaman. The shaman hears the resonant frequencies in his head as hallucinogenic artifacts of the phase transitions happening within his neural oscillators, and when he vocalizes these noises they come out as pitched micro-tones, often layered with vibratos coming from the nose and throat. By layering resonant multi-tones into the sacred song, the shaman increases the amplitude and entrainment power of his neural and vocal oscillators. If the shaman and the ritual participants all sing the same tones together, their oscillators all merge into a constructive interference pattern and drive each other into a higher amplitude of shared energy. This is the physics of neural entrainment and linking group mind.

Chapter 18

Psychic Bonding and Psi

Psychic bonding is a physical, neurological adaptation that occurs when two subjects spend time together sharing thoughts, feelings, and personal space. Psychic bonding is a survival trait that all animals and possibly all plants share. Psychic bonds can create personal vulnerabilities, so the average subject will have a built-in resistance to psychic bonding unless there is an explicit survival need and a certain level of trust established between subjects. Resistance to psychic bonding naturally breaks down over prolonged exposure between subjects living in the same confines as trust becomes routine and implied. In order to form a psychic bond, subjects must spend a period of at least a few hours together; a period of two to three days is optimal. Subjects should be together throughout all daily activities: waking, sleeping, eating, working, relaxing, etc. Sharing the schedules and routines of daily life is essential to synching the circadian rhythms and cross-expectations of each subject.

Psychic Bonding and Circadian Rhythms

Circadian rhythms are the master clock which controls all the state changes an organism undergoes in a 24-hour period. We wake up, get active, get hungry, get relaxed, get sleepy, go to sleep, and dream on a predictable cycle that mirrors the rotation of our planet, our moon, and our own internal biology. Subjects who are synched to the same circadian rhythms are locally bound to the same hourly oscillator, which means they share the same time-zone and daily living schedules. People who are called to perform daily routines at certain hours - like the prayer times of Islam, the coffee and lunch breaks of Western corporatism, or the hourly news cycles of modern media culture - have particularly high levels of local circadian binding. Usually circadian rhythms must be synched before psychic bonding between subjects can begin, though there is anecdotal evidence that psychic bonding can take place over telepresence if virtual contact is maintained for extended periods of time.

Psychic bonding usually takes place within a household; the household can be a metaphor for any group living situation, it can be an actual house, a business or partnership, or it can be a loose tribal structure like a band, team, squad, or similar nomadic crew. When living within close confinement, subjects are forced to work together, compromise, and share rigidly induced schedules for eating, relaxing, and sleeping. As subjects coexist they begin to build internalized constructs of each other which dictate how they behave and interact; these are cross-expectations fed by mirror neurons analyzing cooperative behaviors. The close familiarity between subjects drives a neural wiring process which embeds the patterns of each bonding partner into the other's mind, a process called mutual plasticity. Routine familiarity between subjects drives mutual plasticity.

Stress- and Pheromone-Induced Neuroplasticity

Smell is the most evocative of human senses because it is wired tightly into reward and fear responses, and of all the things that entice and repulse us about other people smell is arguably the strongest. When subjects are living in close proximity they produce hormones, pheromones, and they sweat, and when those pheromones are inhaled they produce instinctual emotional and neural responses. There is a very complex relationship between hormones, pheromones, behavior, mating, and bonding that permeates the entire plant and animal kingdom; it is a subject that transcends molecular biochemistry and approaches organic information field theory. Attempting to break down the non-verbal power of pheromones to induce bonding and neural growth can lead to many interesting digressions, but what is most germane to our discussion is that when humans are under stress they produce hormones and they sweat, and that hormone-laced perspiration induces powerful empathetic responses in other humans. The feedback of pheromonal response between subjects over a period of a few circadian cycles will automatically drive the bonding process even if subjects are naturally resistant. The introduction of stress into the group household will increase hormonal response and thus make the bonding process more urgent and more powerful.

Bonding can be slow and relaxed, like the way a family builds familiarity over time; or it can be fast and forced like the way cults, fraternities, and militias haze subjects into coherence in a matter of days or weeks. Bonding can also be artificially induced through drugs, group mind rituals, or through the stress of surviving combat or a natural disaster with a small group of people. Bonding pairs are most likely mates, partners, roommates, or people who live and travel together in small tribe-like groups. Hostages can also bond with their captors in what is famously known as Stockholm syndrome,[1] which is an example of stress creating a situation where the brain is ripe for entrainment and imprinting.

A romantic version of group mind leading to psychic bonding might happen spontaneously on date when two potential mates sit and talk quietly for long periods of time, sharing vulnerable aspects of themselves over dinner, drinks, and conversation. If the couple is good fit, they will slowly synch into harmony with each other over the course of an evening until they wind up talking all night, feeling like they've never met anyone who understands them so deeply and intuitively. This is pheromones, proximity, and self-reinforcing neural feedback embedding instinctual rhythms in the rapport between two subjects; or neural cross-expectations. The overlap of hormonal response, brain wave coupling, and proximity between subjects will, over time, build strong synaptic connections which bind these individuals together.

Informational Capacities of Bound Partners

While the telepathic capacity of bound subjects is limited, a bound partner can still tell, for instance, what a partner is thinking just by looking at their face. The telepathy is generally not literal and symbolic, it is intuitive and empathetic. Bound partners will share intuitive rhythms of speaking and interacting - sharing phrases, inside jokes, and specialized facial expressions - and will spontaneously fall into these rhythms whenever they are together, even if they have been separated for long periods of time. There is constant anecdotal evidence that bound partners often spontaneously think of each other at the same moment, causing one to call or seek out the other just as the other thinks of doing the same; or that pets intuitively know when their owners are on the way home.[2] More intriguingly there is evidence indicating that bound partners can non-locally sense when the other is surprised, startled, or in danger.[3,4,5] Bonded pairs being synched on an intuitive level may not be literal telepathy, but this can definitely be classified as psi which has obvious survival advantages.

The key capacity of bonded pairs is that they can think and move fluidly as a pack and work instinctively with each other on an intuitive and non-verbal level. The demonstrable capacity for organisms to bond into collective groups emerges at the bacteria level and becomes most obvious at the insect or hive level. Through the mechanistic means of pheromones and receptors, insects can coalesce into a hive mind capable of many coordinated tasks; this is non-verbal cooperation based solely on encoded rules of instinctive behavior. Fish form schools, birds form flocks, mammals form packs, humans form tribes and towns and cities. Humans can also form psychic bonds with domesticated animals such as cats and dogs and horses, cross-encoding verbal and non-verbal communication for simplification of everyday needs and routines. There is also anecdotal evidence of people bonding with plants. The hormonal process for psychic bonding is genetically encoded and instinctual in cases of extended close proximity, intimacy, and stress; these are the exact variables needed for breaking or domesticating wild animals; the same variables needed for brainwashing; the same variables needed for cult indoctrination and deprogramming. The psychic bonding process is an instinctual evolutionary capability which can be exploited for positive or negative purposes, and the quality of information passed through psychic bonds can be described as automatic, self-stabilizing, non-verbal, advantageous, and intuitive.

Chapter 19

Group Mind and Fluid Tribal Dynamics

The physical theory of group mind begins with some basic assumptions about oscillators and wave mechanics. If the mind is a resonant oscillator for processing information, and two oscillating minds can be synchronized through harmonic or resonant wave interference, then two minds entrained in a synchronized state should be able to pass information from one mind to the other. This theory sounds like potential telepathy, but the reality is more subtle and complex. The information that can be shared between oscillators is non-verbal and non symbolic; it exists in the realm of frequencies, wavelengths, and amplitudes. The most common information passed between entrained oscillators is synchrony testing and error correction, self-correcting mechanisms which maintain oscillator stability. Intuitive synchrony testing and error correction between two or more minds coupled in the same circuit is subjectively perceived as nonverbal communication, group mind, intuition, telepathy, or psi.

Examples of synchrony testing and error correction exist in all forms of communication. When information is flowing smoothly between oscillators, the data transfer has high speed and synchrony; when information transfer from one oscillator fluctuates and becomes ambiguous, the other instantly corrects to resolve the instability and regain synchrony. If automatic synchrony testing and error correction did not exist, any fluctuation in signal fidelity across the circuit would make the oscillator decouple. Synchrony testing and error correction can happen in a verbal conversation, a digital packet transfer, a cellular coding system, the harmonic chiming of bells, and so on. Synchrony testing and error correction allows entrained oscillators to retain stability through mutual feedback control, conserving or amplifying energy by phase locking into stable harmonic configurations. Individuals bound in a group activity use intuitive synchrony testing and error correction to maintain harmony through behavioral coordination and unitary cohesion.

Group Trance and Entrainment Technology

A practicing shaman must be a master of at least one ritual entrainment technology, and must be a master of putting himself and others into a targeted trance state; this is the bare minimum, the rest happens naturally. Some shaman simply provide total quiet and let the medicine do the work; some shamen put on elaborate shows which include singing, chanting, and live musical performance. The jam band phenomena started by adapting the dynamics of medicine drum circles to 1960s psychedelic party culture; hence the Grateful Dead and the growth of the Rainbow Family. In the 1990s the shamanic entrainment ritual was reduced to something as mundane as playing records on a loud stereo system with heavy bass, and this mundane task blossomed into the celebrity DJ profession which fuels modern global party culture. Any live performer can tell you that the feedback circuit between musician and audience fuels the energy of the performance, culminating in the moments when the performer and audience all sing the same chorus or move to the same beat in unison. It is the same with churches; it is the same with sporting events; it is the same with the military. When the audience participates in the performance, either dancing or clapping or singing in unison, it drives the amplitude of the entire circuit. This is spirituality, religion, and group transcendence reduced to wave mechanics.

There are two steps to entraining group mind. You must first demand focus of group attention, and then you must masterfully apply the entrainment technology; these rules are immutable and are the same for the hypnotherapist, the shaman, the musician, the salesman, the politician, the TV programmer, and so on. Demanding the attention of a large group of people is perhaps the hardest part, but the ritual entrainment technology can arguably be purchased at retail. In a club setting the focus of attention is commanded by the DJ, who applies prefabricated entrainment rhythms (dance grooves) to the crowd. When the crowd responds favorably to a specific groove by dancing with exuberance, the DJ rewards them by finding more grooves that fall into the same tempo, and then uses dynamic filters to isolate and boost the resonant frequencies of the walls in the room, pushing the music over the top with tremors that literally rattle the earth. When the DJ establishes a strong feedback control circuit with the crowd, there is phase transition where the crowd ceases to be individuals and they cohere into a single fluid unit. At this point the crowd becomes synchronized in audio-motor synesthesia with the music, almost like puppets (Fig. 25). The physical dynamics of a group of people engaged in trance dancing defies formal social descriptions and is best described as a coherent wave interference pattern.

Group Mind and Behavioral Phase Transitions

This spontaneous movement of a group of individuals into a coherent organism can be described in terms of phase transition from solid state to a liquid state of group dynamic. In the solid state there is ego, language, etiquette, social hierarchy, and rules of one-on-one engagement that keep individual identity separated and solid; in the liquid state individuals drop social pretenses and merge seamlessly into the flock, navigating instinctively via environmental cues and mutual feedback. When a group of individuals moves from a solid to a liquid state, there is a sense of transcendence that is subjectively perceived as joyful, cathartic, and spiritual. Subjects in a liquid group state feel unity, love, and purpose as the energy of the crowd flows through them like a transistor in an electrical circuit.

A similar example of social dynamics passing from solid to liquid state occurs in flocks of birds. On the ground birds assume pecking orders which create the dynamic for mating and nesting, in the air they become a fluid unit that navigates as a seamless whole. This social phase state transition is observable, repeatable, and may be measured generally in terms of global power across alpha bands of the entire group. In the ego-driven beta state the solid norms of society and hierarchy apply, but in the relaxed alpha state behaviors become more fluid and intuitive. In the beta state the individual is concerned only with fulfilling their own rational agenda; in the alpha state the individual moves seamlessly with the flow. When the tribe adopts a fluid social state it becomes a temporary autonomous zone for interpersonal experimentation, identity play, and other ego-blurring experiences that reinforce intimacy and group loyalty.

Informational Capacity of Group Mind

Shamanic mythology tells us that tribe members synchronized to group mind enter a telepathic dream-space where they can all share thoughts and visions. The sensation of bonding and becoming one with the group is real, but the level of telepathic ability achieved in group states is debatable. In a group trance the rational ego is detached and non-verbal intuition is fully engaged; empathy bonding is high and the hallucinogenic medicine turns group intuition into concrete visions. This enhanced non-verbal intuition can be called telepathy, psi, or a shared dream-space, but it would be wrong to assume that each member of the tribe is automatically sharing the same thoughts or visions just because they are all synchronized to the same hallucinogenic control wave or entrainment frequency.

The informational capacities of group mind are limited in a number of ways. Mutual feedback synchrony between peers coupled in group mind is nonverbal, local, and time dependent. At a distance peer and group coupling becomes weaker, and this coupling grows weaker the longer peers are separated by distance. Many traditional shamanic ceremonies recur weekly, or perhaps monthly with the phases of the moon. Shamanic ceremonies often employ the ritual of the medicine circle, a literal circuit of individuals bound in the ceremony for the duration of the ceremony. Breaking the circle in the middle of the ceremony is strongly discouraged, because energy shared and amplified in the circle can escape into the ether instead of staying within the group. Creating the sacred circuit on a recurring basis extends the power of non-local peer coupling over the periods between ceremonies, allowing for extended synchrony at a distance as long as the circuit binds locally or meets to synchronize at regular intervals. Recurring group circuits, such as shamanic ceremonies, church attendance, weekly business meetings, social clubs, and so on, reinforce instinctive behavioral cohesion and cross-expectations between group members.

Group mind can accurately be described as a form of distributed cognition, where the units of a group are coherently bound in a larger integrated system or process. From a distributed standpoint group mind is not literal telepathy, it is instead a form of cooperative thought emerging simultaneously as part of the coherent group process. Distributed functioning in the insect kingdom is commonplace; in the animal kingdom it takes the form of group movements like flocking, herding, and schooling, but sometimes emerges in more complex actions like hunting and stalking. The information shared in distributed tasking is limited to intuitive coherence of motor behavior to fulfill specific tasks and group functions. Behavioral cooperation and functional stability in group mind states is mediated through intuitive, nonverbal synchrony testing and error correction between coupled peers. In team sports and military operation, this highly intuitive group state is sometimes called being in "the zone."

Chapter 20

Shamanic Sorcery

Shamanic sorcery is the craft of manipulating the fabric of psychedelic space for personal gain or vendetta. Powers ascribed to shamanic sorcery include clairvoyance, spirit channeling, shape shifting, astral travel, remote viewing, curses, dream projection, magical darts, telepathy, mind control, necromancy, and so on. The shamanic ontology, or psychedelic spirit space, can be cynically viewed as a shared non-physical, non-temporal delusion accessible to any shaman as long as they accept the rules of the central ontology. In this way the shared shamanic ontology becomes fluid through space and time, and is magically manipulated and reinforced through ritual use of psychedelic drugs. In a setting where the shamanic ontology is readily accepted and reinforced, the shaman has great power; in reductive scientific settings that refute the shamanic ontology, the shaman appears to have an overactive guru complex and delusions of grandeur.

While PIT may appear to discount the claims of shamanic sorcery and spirit channeling, very few scientific studies have been done to either verify or refute the efficacy of psychedelic sorcery. A close reading of the literature on psychedelic discovery by the West reveals that scientists, therapists, and academics have rushed to exploit the power of native visionary ritual without properly considering the cross-cultural psychic backlash.[1,2,3,6] If the shamanic space is purely delusional then modern advocates have nothing to fear by exploiting traditional psychedelic ritual; but if the shamanic space is a transpersonal information field then it should also be considered a battlefield for waging information warfare. Modern advocates cannot embrace the entheogenic side of psychedelic spiritual communion while simultaneously ignoring the darker aspects of a truly transpersonal ontology. Like the internet, which allows peers to couple in unique ways, a shared shamanic network for sending and receiving information is also a vector for potential treachery and attack.

Sorcery and Nonlinear Influence

From a reductive standpoint, the shaman's magical influence is limited only to his tribe members, local neighbors, or those within his personal network; influence within this sphere is easy to account for in purely physical terms. From a metaphysical standpoint, the shaman is also said to be bound non-locally to all spirits and shamen in the psychedelic space regardless of physical or temporal location. The shaman is also said to be able to enter people's dreams, making the destabilized world of fleeting nocturnal visions like a global river for the shaman to navigate. These transpersonal claims are harder to account for in physical terms, and recent theory has attempted to tie the shamanic space to a non-local Akashic or morphogenetic field where non-physical spiritual or biological information is stored and transmitted.[4,5] A shared morphogenetic field should infer evolutionary advantage, but it also implies non-local vulnerability. Attack sorcery often requires a clipping of hair, a fingernail, a personal item, or a totem of the attack target. From a morphological perspective the sorcerer uses the genetic traces of these items as a resonating antenna to attack the target directly through the morphic field.

Under the influence of psychedelics, the shaman can hear the chattering of nonverbal information coming from the jungle, the city, the plants, the animals, and can intuitively sense the natural rhythms and cycles receding into the past and future. The shaman can blow a curse into the passing wind, or at a passing animal, and send magic darts on convoluted pathways towards enemies. From a nonlinear standpoint sorcery does not have to make rational sense. The placebo effect is a positive example of a nonlinear result that does not make rational sense; the same can be said for a curse that causes an enemy to suddenly fall ill. These results only make sense if you analyze them from a longitudinal perspective and follow the small periodic permutations of system variables as they produce disproportionately complex results through time; recovery in the case of placebo, or sickness and death in the case of a curse.

According to the fundamentals of Psychedelic Information Theory, the influence of shamanic sorcery can be presumed to be nonlinear, which means small periodic perturbations of system variables within a larger information system can produce disproportionately complex and chaotic results in any other part of the system. In the nonlinear psychedelic space the shaman is a chaos magician, or the butterfly that flaps his wings in China and creates a hurricane across the ocean. The nonlinear aspect of psychedelic sorcery makes it both a very subtle art form and something that escapes reductive scientific observation, but also makes it very prone to failure and lack of proper control. The weather is famously nonlinear, and one of the jobs of the shaman is reading and controlling the weather; this not a coincidence. PIT assumes that the study and mastery of nonlinear systems and emergent longitudinal complexity is a fundamental part of all psychedelic shamanism and sorcery.

Synchronicity Magic and Probability Collapse

Subjects in a destabilized nonlinear state often report enhanced sensations of non-random coincidence, or synchronicity, that appear to defy all rationality. Accounts of hidden forces acting in concert to send messages through non-random coincidence are common in psychosis, paranoia, schizophrenia, mania, bipolar disorder, and psychedelic intoxication. On psychedelics this state is dose dependent and increases in complexity with larger doses, until it appears the entire fabric of reality, down the subatomic level, is speaking directly to the subject with a singular narrative message. While in this "synchronicity hole," nothing in the universe seems random and all coincidence is laden with profound subtext that makes sense only to the subject. From a clinical standpoint, the synchronicity hole represents a state of delusional megalomania, yet this is exactly the kind of logic we should expect from a nonlinear analysis of reality. Linear analysis may perceive the leaves on a tree as a random distribution; a nonlinear analysis will see a singular non-random function underlying the genesis of complex form.

Subjective accounts of the synchronicity hole describe an immediate precognitive insight where probability appears to collapse and the subject intuitively knows exactly what is going to happen next. Another common description is that psychedelics open the mind to unlimited potential pathways into the future, and those potentials expand and collapse through time in direct response to the behaviors and will of the shaman. A shaman in this space is said to be able to look forward in time into many probable futures, and can choose any future simply by stepping into the vision and following the pathway that leads him there. By applying synchronicity magic and selecting non-random pathways into the future, the shaman expands and collapses probability and subtly alters the fabric of reality by choosing a new destiny. This process can be described in terms of deterministic chaos driving a superposition in subjective identity, leading to radical identity potentiation, behavioral change, and self-actualization through deterministic neuroplasticity.

Sorcery and Negative Information

According to PIT, shamanism is the craft of generating positive or stabilizing information within a larger matrix; sorcery is the craft of generating negative or destabilizing information within a larger information matrix. Negative information is any information which seeks to subvert or destroy parts or all of the larger information matrix. Examples of negative information at the biological scale include viruses, parasites, toxins, and cancers; at the personal scale negative information may include doubt, fear, stress, depression, abuse, neglect, trauma, and delusion; at the tribal level negative information may include dishonesty, distrust, withholding, disinformation, and warfare. When negative information is amplified with positive feedback, it can grow to destroy the entire system. Negative information can be countered with negative feedback, or dampened by positive information which seeks to bring stability back to the matrix. While a shaman uses psychedelics as a medicine or sacrament to heal and maintain tribal stability, the sorcerer uses psychedelics as a weapon to gain power over peers and attack enemies.

If shamanic sorcery is a kind of nonlinear chaos magic, it should also be considered to be somewhat unpredictable, uncontrollable, prone to high rates of failure, and potentially dangerous. Moreover, it is right to be suspicious of people interested in sorcery, which can be formally defined as negative information warfare waged for personal gain. Common wisdom dictates that when studying psychedelic shamanism one should learn under a *Maestro*, or master, who offers spiritual protection against black magic and sorcery.[3] While it is easy to dismiss these claims as superstition, the ambiguities and temptations of psychedelic sorcery have not been adequately addressed in the context of modern entheogenic ritual and clinical psychedelic therapy. Anyone experimenting in the field of psychedelic shamanism should be careful to avoid the dangers and temptations of sorcery.

Chapter 21

Spirits and Spiritual Communion

Spirit contact is a central part of many psychedelic practices. While the autonomy of spirit entities is a subject for endless metaphysical debate, the reports of seeing spirits under the influence of psychedelics are common enough to make some generalizations. First, psychedelic entities are anthropomorphic interfaces through which psychedelic information is generated or transmitted. Second, formal spirit types represent idealized versions of specific information matrices: cellular, insect, plant, animal, ancestral, mythic, alien, pagan, machine, cosmic, and so on, and each type of spirit reveals different insights into the ordered nature of life and the universe. Third, psychedelic spirits are tricksters; they often speak in riddles, communicate in visual rebus and pantomime, and typically never give a straight answer to inquiries. From an information standpoint it does not matter if the spirits are real or delusion, the information they generate is real and can be analyzed from a formal perspective.

Habits and Customs of the Spirits

A study of the literature on shamanism and helper spirits tells us many things about their behaviors and habits. First, spirits do not generally like light; they will occasionally appear in the daytime, but they prefer to appear in dim light, at night, in an area illuminated only by candle or firelight. Second, spirits usually come only when you call them, only after you have called them, in the long moments of silence following the request for them to appear. Third, spirits do not like loud noises; keeping the entire local area perfectly quiet is the only way to ensure they will feel safe to appear. Fourth, spirits do not like foul smells, they are drawn to the perfumed scents of tobacco smoke and various types of incense, and are repulsed by the smell of meat-eating humans, alcohol drinking humans, and menstruating women; foul smells may actually summon harmful spirits or demons. Finally, some spirits require that the shaman grovel, chant, sing, and produce offerings before they appear; this is not always required but is common enough to be considered typical. To call in the spirits the shaman must respect all these customs while taking large amounts of the psychedelic medicine. The spirits will only come if the shaman calls them at the proper time and place, after he has dieted and purged, taken the medicine, and then burned enough tobacco or incense to make the scent of the area meet stringent requirements.[1]

The ritual for calling the spirits includes many telling details. Fasting and a low-sugar, low-protein diet implies physiological tuning for destabilizing metabolic homeostasis. The doses of hallucinogen taken in spirit communion are high, typically twelve or thirteen pairs of psilocybin mushrooms for traditional Central American ceremonies. Ritual intonation of calling in the spirits, or requesting for them to appear in chant or song, sets the initial conditions for the hallucinogenic experience which follows. Stillness, low light, and silence offers the best conditions for acetylcholine modulation of the midbrain associated with sleep onset, which is known to produce dream-like imagery. Tobacco excites cholinergic modulation of the midbrain. Incense excites olfactory reward centers in the midbrain; foul smells excite olfactory anxiety centers and naturally produce visions that are more demonic than angelic. Psychedelics interfere with smooth muscle contractions related to digestion and uterine cramping, making hallucinogen use potentially uncomfortable for menstruating women, and potentially dangerous for pregnant women. The final element in the ritual is having faith that the spirits will appear, which reinforces the intonation and expectation that they will. And, surprisingly enough, if you follow the ritual exactly and have faith, the spirits will appear.

Interfacing with Spirit Information

If the shaman follows ritual protocol, ingests the psychedelic medicine, and manages to summon the spirits, he should not waste time bothering them with mundane questions. The spirits will typically answer only one question or perform only one task, and that task should be considered urgent and worthy of their participation or they will promptly dismiss the shaman and will not appear again for the rest of the session, perhaps not again for many weeks or months. Spiritual dismissal is reported often enough to be considered typical, so the formal spiritual quality of being offended by mundane inquiries should be noted when attempting to access spirit intelligence. By all accounts, forging reliable relationships with specific spirit entities takes time and requires a fair amount of dedication to learning their habits and ways. The information in the spirit matrix should not be considered a database you simply plug into and access like the internet, but more like a network of individuals whose trust you must gain and keep over a lifetime in order to share their wisdom. Traditional shamen report that one of the worst things that can happen is for the spirits to stop appearing because the shaman has lost his power or offended them in some way. Staying on good working terms with the spirits is a core theme of shamanism and retaining shamanic power.

Gnosis, the All One, and Nonlinear Communion

Subjective accounts of psychedelic transcendence often include reports of a cosmic connection to a single unified force, a force which sometimes speaks to or through the subject. This force does not appear physically or anthropomorphically, but instead appears to be imbued in the fabric of all things. Typically the subject is meditating, is lying still, is engaged in breathing exercises, or has a similarly detached focus when the voice begins to speak. When this force speaks it is through a layered nattering and murmuring arising from seemingly random and unrelated background noises. In a destabilized state, these random background noises synchronize into a coherent pattern of linear, directed communication from one fundamental source. When the fundamental source energy senses the subject's heightened awareness, it begins to coalesce and speak through his or her mind. This voice typically introduces itself in the subject's language with the slowly repeating phrase, "I am the All One, all that is, was, and will ever be."[2]

The All One is subjectively perceived as the mind, consciousness, will, and intent of the physical universe. There is often a sense of reverence, love, acceptance, and unity infused with the contact. Formal accounts of communion with the All One date back to the origins of Hermeticism and Gnosticism, and depict a pantheistic, teleological view of the universe as the sacred physical body of an ever-evolving omniscient God. Formal accounts of the All One clearly depict the scale of timeless omnipresent omniscience we would come to expect from God. If we are to take the formal description of the All One literally, it can be implied that the voice of God is always present, constantly repeating and speaking through the sounds and rhythms of the natural world. There is only one requirement for communing with the All One; the voice is only accessible to people who have destabilized linear perception and can parse environmental data in novel, nonlinear ways.

In accounts of mysticism and madness, God only speaks to people in states of heightened destabilization: deprivation, psychosis, schizophrenia, stress, fever, dream, trance, and hallucination. Because of this it is easy to assume that hearing the voice of God is a symptom of insanity. According to PIT, when the brain destabilizes due to hallucinogenic interrupt, it will naturally seek coherence with the strongest local periodic driver. In some cases the strongest local driver may be the shaman, it may be the jungle, it may be the refrigerator, it may be the city, it may be the croaking of frogs and crickets, it may be a jaguar stalking in the distance, it may be Gaia, or it may be God. Another way to look at it is this: God is a timeless nonlinear being; in order to hear God's voice we must be able to achieve the stillness and silence necessary to perceive and parse longitudinal nonlinear input. Without debating the metaphysical existence of God, the formal techniques for subjectively communing with the All One are reliable and repeatable, and can be readily achieved through temporary, reversible destabilization of linear perception via psychedelic drugs.

Information Capacity of Spiritual Communion

A commonly repeated theme in spiritual shamanism is that spirits are fickle and their information should not always be trusted. This is perhaps a metaphor for all psychedelic information, or information revealed in a state of nonlinear destabilization. Common sense would dictate that if spirit information is unreliable it should be uniformly discounted as delusion or insanity, but subjective reports and clinical studies show that people find great value and utility in the information generated in psychedelic experience. Common sense also dictates that the information capacity of spirit information cannot exceed the existing knowledge of the subject, but subjective reports claim that psychedelic visions reveal new wisdom all the time. The overall information value of psychedelic shamanism is thus debatable.

Since no studies exist to validate the authenticity of psychedelic spirit information, it is impossible to estimate the actual information value. From a statistical analysis we can assume that nonlinear psychedelic information emerges into consciousness at speeds far greater than linear information, generating a large pool of abstract ideas in a very short period of time. Many of the ideas generated in a psychedelic session may be delusional or fantastical, but because of the sheer volume a small percentage of them are also destined to be insightful and genius. Within the flow of psychedelic information it is up to the subject to decide which bits are useful and which bits are not, and the trick of this disambiguation comes when attempting to translate nonlinear insight to linear concepts, beliefs, and behaviors. If nonlinear insights compress easily to linear concepts, then spirit information may be of high value; if nonlinear insights are confusing or defy rationality, then perhaps the spirits are up to their old tricks again. Either way, spirit information should always be carefully parsed and analyzed for trickery and deception before being acted upon or integrated into belief.

Chapter 22

Information Genesis and Complexity

The emergence of new information over time was the obsession of psychedelic philosopher Terence McKenna, and he popularized the term Novelty Theory to describe the phenomenon of increasing information complexity in the universe through time. In order to graph the emergence of novelty through time, McKenna created an occult formula based on the hexagrams of the I Ching, and charted a jagged line that starts at zero and tops out at infinity; what he called Timewave Zero. McKenna's observation that novelty appeared to be speeding up led him to believe that time was approaching a singularity where all information tops out at infinity, set to occur on December 21, 2012.[1] The infinite complexity McKenna describes is actually the opposite of a singularity (which is zero complexity), but McKenna's observations about novelty speeding up were essentially correct. Although many people have adopted McKenna's 2012 singularity meme, the occult construction of his Timewave and other aspects of his 2012 prophecy have left many unconvinced.

Psychedelic Information Theory approaches novelty and information genesis from a different perspective than McKenna. McKenna viewed novelty as a trend line that begins with the start of the universe and speeds forward from zero until infinity, which is accurate but is also misleading at the same time. McKenna also does not differentiate between types of information and the contexts in which new information emerges; this is also a problem. By blending all information together into a single trend line, it would appear that novelty is speeding up and will soon top out at infinity, but this trend line flattens out if you consider that information exists in various states, and that each state generates information at a more or less constant rate depending on state energy density.

To illustrate the fundamentals of energy density and information complexity I have created a table that delineates the emergence of quantum levels of information systems over time, and the type of information each system generates (Table 2).

Info State	Δ^n	Time of State Change	Information Type
Singular	Δ^0	+15 billion years ago	Singularity, no information
Fundamental	Δ^1	15 billion years ago	Force breaking, strong force, electromagnetism, gravity
Luminous	Δ^2	14.99 billion years ago	Cosmic radiation, light, heat, subatomic particles
Gaseous	Δ^3	14 billion years ago	Simple atoms, hydrogen, helium, galaxy formation, stars
Elemental	Δ^4	11 billion years ago	Heavy elements, star collapse, novas, spread of heavy matter
Organic	Δ^5	4 billion years ago	Complex molecules, organic chemistry, replication, plant life
Animal	Δ^6	500-50 million years ago	Nervous systems, connective logic, memory, consciousness
Technological	Δ^7	3 million years to today	Tools, symbols, art, language, manipulation of matter and energy
Post-Tech	Δ^8	Distant future	Post-terrestrial, AI, nonlinear time and space, n dimensions

Table 2. Emergence of information systems over time: Information emerges into the universe within formal stages, each stage marking a quantum leap in energy density and the speed and complexity at which new information is produced.

Since information is created by state change over time, I have used the symbol Δ (delta, as in delta-one, delta-two, etc.) to denote stages of information creation. Each stage in the matrix represents a quantum leap in the order of energy density and complexity of information being generated, and novelty creation in the universe accelerates with each of these quantum leaps. Each stage relies on the information created in the previous state to move forward with increasing physical density and complexity. This model takes into account the Big Bang theory and the best guesses of modern astrophysics and cosmology as to when each new information level emerged, but the story of information genesis in the universe goes something like this.

Starting at Δ^0 we have the pre-Big Bang singularity where all information is condensed into a single infinitely small point. There is no state change over time, so there is no information. Around fifteen billion years ago there was a Δ^1 state change we call the Big Bang, in which the uniform singularity breaks into the fundamental forces of physics: strong nuclear force, electromagnetism, and gravity. At this stage God says "Let there be light," and we have the emergence of cosmic radiation and nuclear fusion which allows subatomic particles to form, leading to a Δ^2 state change where simple hydrogen and helium atoms can stabilize; the first matter created from condensed particles of energy. The gravity drag on this new mass allowed a Δ^3 state change where globular clouds of gasses clump and then collapsed inward, creating spinning galaxies of exploding stars fueled by nuclear fusion. When stars begin to exhaust their energy and collapse inward, there is a Δ^4 state change that allows for the creation of all the denser elements on the periodic table that can store more cosmic energy within a single point, or an atomic nucleus, which is comprised of particles of compressed energy.

The Δ^4 state represents the galactic preconditions necessary for life as we know it - the "firmament" - and in order to create the dense elements needed for life you need the fundamental forces of physics (Δ^1), an energy radiation source (Δ^2), the formation of simple gasses (Δ^3), and billions of years of nuclear fusion (Δ^4). At each stage you have a modest increase in the complexity of physical interactions which allows for new information genesis, but at the Δ^4 stage following star collapses and supernovae, we finally have the raw materials for terrestrial formation: heavy metals. A glob of heavy metal orbited our local star (the sun) and cooled to form a solid planet. As our planet cooled, liquid water formed on the surface and oxidized the metal on the outer crust, creating the nutrient-rich salt-water conditions for a Δ^5 stage change in the formation of complex molecules held together on strands of charged hydrocarbons. This marks the beginning of life.

The Δ^0 to Δ^4 information states are pre-organic and are therefore only interesting to physicists, astrophysicists, and mathematicians, but the Δ^5 information matrix is the matrix that chemists and microbiologists study; it is the study of the conditions in which energy is stored and transferred through molecular bonds. When shamen and mystics tap into the web of life and the primal force that connects all living things, they are tapping into the Δ^5 information matrix, which is sometimes described as an invisible electromagnetic field which permeates all creation, or the invisible landscape. The visual representation of this living energy field is most acute under the influence of tryptamine hallucinogens such as psilocybin and ayahuasca (DMT), and the source of this field is often perceived to be divine in origin, leading to many interesting speculations about spirit realms, Akashic fields, morphogenetic fields, and the like. Whether or not tryptamine visions are accurate representations of the electromagnetic field is a matter for some debate, but the overwhelming number of subjective accounts make the appearance of this field difficult to deny.

The Δ^5 matrix is the matrix which sustains our life; it is at work in our cellular functioning and metabolism right now. The Δ^5 matrix allows for the creation of new information at a rate that far exceeds previous information stages, and information genesis at this stage happens at the level of nucleotides, DNA, RNA, enzymes, proteins, and the organic chemistry of replication, proliferation, mutation, and Darwinian selection. Life excels at taking inert matter and organizing it into more complex forms, and in a few billion years life evolves from single-celled organisms to complex animals, representing a Δ^6 state change that allows for the development of motor nervous systems and rudimentary organism consciousness. The Δ^6 matrix relies on the Δ^5 organism matrix for cellular energy and nutritional support, but it represents a state change because the information stored in the Δ^6 matrix is neural, connective, and allows for internal storage of external state properties (or memory) at the organism level. The same connective neural network needed to control muscle behavior while navigating the external world is adapted to store memories of the external world for later use, and this internal neural storage increases organic information complexity from simple cellular organization into connective representational and symbolic logic.

The Δ^6 state change marks the most important quantum leap in the entire information chain because at Δ^6 organisms begin to internalize external data into personal connective networks. With the development of animal consciousness, the universe begins to map properties of the physical world (objective information) into connective logic stored in brains (subjective memory). Information in the Δ^6 state flows intuitively through animals in the alpha state, the tribe mind, the hive mind, and the fluid pack. The Δ^6 information matrix is semiconscious, instinctual, and routine; it is where nonverbal intuition, habitual behavior, and psychic bonding occur.

After hundreds of millions of years of animal life there is another state change brought about by evolution and morphology, the early primate adaptation of the fine finger dexterity needed to use tools. The ability for an organism to incorporate an external tool (like a rock or a stick) and a specialized skill (like throwing or pounding) into daily behavior heralded the age of technology, and with the Δ^7 state change came a corresponding shift in the speed and complexity of technological information which grows ever faster and more complex to this day. From sticks to fire to wheels and alphabets and machines and computers, hominids have excelled at incorporating information into their brains, rearranging it, and using it to externalize new information and technologies. The story of Δ^7 information genesis is the story of human culture itself, the organized spread and control of information through hominid tribal groups leading to power, civilization, empire, and industry.

The Δ^7 information matrix represents another quantum leap in information genesis, storage, and transmission. The logic networks created by internalizing reality in the neural Δ^6 matrix are used to create new information which is externalized in the form of technology, language, art, media, and invention. The Δ^7 information state is the realm of language, logic, critical thinking, science, and rational analysis. Modern culture cherishes the Δ^7 information space above all others, this is the space where the tools of mythology, religion, politics, and mathematics emerge. The Δ^7 information space occupies an ego-driven, distracted, beta state of critical self-awareness. Like charged particles seeking to find electromagnetic balance, the human in the Δ^7 state will seek to correct or improve perceived problems with external reality via subjectively controlled ingenuity. Total mastery over the subjective manipulation of matter and energy is the ultimate goal of the Δ^7 information state, the state humans have almost perfected. Now that we have the internet, supercolliders, nanotech, and atomic bombs, all of these technologies seem to herald another quantum information state change in the near future.

The Singularity and Post-Technological Matrices

The Δ^8 information state can be called the post-technology state, and much like McKenna's Timewave Zero, the technological Δ^7 information matrix must eventually top out with the end of science and the complete integration of all physical forces into human technology. This seems like it is happening quickly, but going by trends in previous state changes the singularity isn't likely to happen for another fewhundred-thousand to a million years from now. Though it is currently impossible to imagine what a Δ^8 information space might be like, subjective control over the very fabric of space and time may become possible, allowing something like personal access to space travel, time travel, alternate time streams, and/or an infinite number of parallel dimensions. From the perspective of a Δ^7 information state, a Δ^8 state change would look like subjective human information topping out at infinity; Δ^8 consciousness will have instant access to everything there is to know about humans, technology, the universe, and whatever lies beyond. I believe this Δ^8 state transition is what McKenna perceived in his novelty wave as the end of information.

If we are to follow the permutations of information complexity to date, it is logical to assume that the technology created in the Δ^7 matrix will directly contribute to the fundamental state variables needed for a Δ^8 state change. This can be interpreted to mean that machine code is the next level of information energy density and computers will drive complexity and information genesis into the Δ^8 state. Perhaps this transition is already underway, and is approaching a quantum leap in technology where computers begin generating information and complexity for their own purposes. Only time will tell if this is the case, but in a few hundred thousand years it is conceivable that machine intelligence will be ubiquitous throughout the galaxy, and the end-point of our technology will become the initial conditions needed for the evolution of a more durable and complex matrix.

Shamanism and Information Matrices

When a shaman enters the trance state and searches for new information, there are specific levels of knowledge which are more helpful than others. For instance, when entering group mind with the tribe, the shaman will want to access a pre-technology Δ^6 information matrix where primal animal consciousness, non-verbal communication, and pack bonding instincts are strongest. If the shaman wants to commune with plant intelligence he will enter into a Δ^5 matrix of cellular metabolism and genetic expression; this is also where the shaman will diagnose disease and attempt healing by visualizing and diverting the flow of metabolic energy through the patient's cells with bodywork and sound. Some shaman may also commune with the more cosmic levels of awareness, but shamanism is essentially a Δ^7 technology used by Δ^6 organisms to access information available in Δ^{0-5} matrices; information which is always present but is normally invisible or beyond the limits of human perception.

Conclusions and Discussion

Conclusions

The primary tenets of Psychedelic Information Theory dictate that hallucinogens generate information by destabilizing linear perception to promote nonlinear states of consciousness; that these states amplify initial conditions provided by set and setting; that these states increase in nonlinear complexity in response to dose of hallucinogen, duration of effect, and strength of sensory stimulation; and that the depth or complexity of psychedelic hallucination can be controlled through pitch-timed, rhythmic, or periodic sensory feedback stimulation.

The tenets of the Control Interrupt Model dictate that top-down feedback control of multisensory perception must be destabilized before consciousness can bifurcate, become nonlinear, and generate hallucination; that the destabilizing interrupt of any hallucinogen can be felt subjectively as a periodic pulsation or interference pattern in the range of human sensory temporal aliasing; that sensory complexity or animated progression of hallucination iterates along the frequency of the periodic interrupt; that each hallucinogen has a distinct sensory interrupt frequency and ADSR envelope based on its affinity and selective agonism in sensory binding pathways; and that the unique interrupt and ADSR envelope created by each molecule is responsible for its unique hallucinogenic patterns and multisensory signatures.

The tenets of Shamanism in the Age of Reason, or Physical Shamanism, dictate that a shaman can intuitively sense the interrupt frequency and ADSR envelope of any hallucinogen simply by ingesting a small amount of the substance and paying close attention to the interference patterns created in perception; that shamanic *icaros* or standing vocalizations use harmonic interference to drive or dampen the amplitude of hallucinogenic interrupt; that driving the amplitude of hallucinogenic interrupt increases depth of iteration and complexity in nonlinear information organization; that shamanic dieting and purging is a precursor to destabilizing metabolic homeostasis necessary for holistic nonlinear re-modulation; that bodily transcendence relies on full nonlinear amplification along all cellular signaling pathways, from the gut to the cortex; and that full nonlinear breakthroughs, or psychedelic peak experiences, are only achieved once top-down homeostasis is fully interrupted and the subject releases all inhibitory feedback control over the resulting emergent process.

The basic conclusions taken from the tenets of Psychedelic Information Theory, the Control Interrupt Model, and Physical Shamanism are as follows.

1. Psychedelics generate information in the human organism via nonlinear feedback amplification of both intercellular (neural) and intracellular (cytoplasmic) signaling mechanisms.
2. The nonlinear amplification of sensation exploits excitatory feedback mechanisms used to create lasting emotional attachments to salient sensory patterns in the wake of strong incoming stimulus.
3. Psychedelic hallucination and expanded states of consciousness represent nonlinear amplification of initial conditions of biology, perception, memory, behavior, and location, otherwise known as set and setting.
4. Nonlinear amplification of sensation promotes neuroplasticity and cellular regeneration via hormonal and stress-based mechanisms related to cell proliferation and long-term memory consolidation.

5. Periods of chaotic transition between multi-stable states of consciousness are subjectively perceived as disorienting, confusing, and uncomfortable. Periods where chaotic transitions approach strange attractors and phase-lock into multi-stability are subjectively perceived as ecstatic, beautiful, spiritual, insightful, cleansing, healing, and transcendent.
6. Extended periods of iterating complexity in cellular networks leads to states of consciousness perceived as enlightening, mystical, infinite, god-like, timeless, Gnostic, and omniscient.
7. Resistance to nonlinear destabilization under the influence of psychedelics results in anxiety spirals, panic, and potentially paranoid and psychotic states.
8. There is an optimal dose range for any hallucinogen where states of nonlinear organization and strange attractors spontaneously emerge. Moving beyond the optimal dose range results in highly unpredictable, uncontrollable, and problematic states of consciousness resembling psychosis and schizophrenia.
9. States of nonlinear organization in neural networks can be stabilized through energetic periodic drivers, such as music, singing, chanting, and dancing; making psychedelic consciousness multi-stable along a range of complex output.
10. Through entrainment and mutual feedback, nonlinear states of cellular signaling can transcend individuals to promote pack mind, group mind, peer bonding, mate bonding, and spontaneous nonverbal organization of tribal or familial structures.
11. Shamanic healing, entheogenic transcendence, and psychedelic creativity all utilize nonlinear amplification to generate novelty in the form of spontaneous energetic organization in cellular signaling systems.
12. Because psychedelics produce uniquely nonlinear states of consciousness, any art which evokes recurrence, chaos, and nonlinear forms will be immediately recognizable as psychedelic.
13. Nonlinear forms are perceived to be inherently beautiful and spiritual because they are isomorphic of ordered complexity in the generative processes of biology and nature; thus psychedelic hallucination is perceived as inherently beautiful and spiritual.

Discussion

The fundamentals of PIT were assembled through formal analysis of hallucinogenic states, shamanic ritual, and subjective reports of expanded consciousness. PIT is a general theory, which means it seeks to model an approximation of psychedelic information complexity emerging into human consciousness and cultural memory. PIT applies existing physical models and mathematical concepts like wave mechanics, coupled oscillators, and deterministic chaos to the processes of perception and consciousness. Some components of PIT's general theory can be easily modeled with mathematical or mechanical counterparts; other components are assumed or presumed from observation and published research; and other components are pure speculation or are left purposely vague due to lack of proper corroborating research. Some of these assumptions, speculations, and missing pieces are discussed here.

First and foremost, PIT assumes that the human brain acts as a resonant oscillator, and that consciousness is the result of time-synchronized interference patterns of recurrent neural spike trains cascading through the neocortex. This is not a radical model, it is based on the fundamentals of neural oscillators, periodic drivers, wave entrainment, resonance, and coherence. Entrainment is the capacity for one oscillator to synchronize the frequency of a group of oscillators; resonance is the capacity for one oscillator to drive the amplitude of another oscillator; coherence is when two oscillators phase-lock into stable resonant or harmonic interference patterns to conserve or amplify energy. Classical wave mechanics and the behaviors of feedback coupled harmonic oscillators are the starting point for almost every new concept introduced in PIT.

The Control Interrupt Model and Physical Shamanism both invoke resonant wave interference as a means of producing coherent patterns of nonlinear organization in oscillating systems. Using sound or vibration to produce spontaneous organization of matter is also known as cymatics, which can be demonstrated with sand on a vibrating steel plate. As the steel plate vibrates at various resonant frequencies, the sand will spontaneously move from chaotic to organized patterns, also known as Chladni patterns or nodal patterns (Fig. 31). Cymatics is an example of oscillating systems finding stability at normal modes. Modal vibration can be characterized by period doubling or halving a system's fundamental frequency to create harmonic interference at one of many possible resonant frequencies. This is a mathematical concept that applies to music, coupled oscillators, modal theory, quantum theory, standing waves, and so on.

Analyzing the brain, perception, and consciousness as a single standing wave or resonant oscillator is a very crude simplification of much more complex sensory process, but the general models of feedback control, destabilization, and chaos apply universally in all oscillating systems. Framing the discussion of psychedelics and shamanism in terms of the nonlinear dynamics of resonant oscillators may not shine light on the entire psychedelic experience, but it provides a comprehensive and succinct formal approximation of perceptual complexity generated in expanded states of consciousness, which is the ultimate goal of PIT.

By invoking stability and chaos in perceptual networks, PIT also assumes there are specific organized-chaotic states of psychedelic consciousness that act as strange attractors to pull perception towards multi-stable convergence points. PIT also implies that resonant periodic drivers, such as shamanic singing or drumming, can entrain, stabilize, and amplify convergent multi-stable psychedelic states, or equilibrium states, to induce healing, transcendence, and group mind. However, PIT offers no specific descriptions of precise shamanic frequencies or equilibrium states as practical evidence of this theory. Because the published research in the field of psychedelic brain scanning is limited, the assertions of shamanic entrainment and multistate phase locking are speculative and based solely on subjective reports and observation of the dynamics of shamanic ritual. PIT provides no formal definition for what a multi-stable psychedelic state looks like on a scanning device compared to a normal state of consciousness, nor does it say where or how one should scan for the best statistical indicators of such states. This is an issue that can only be resolved through statistical analysis of many controlled psychedelic scanning sessions in the presence of live music or shamanic ceremony compared against sessions of meditation or trance dancing. It may be decades before such research becomes available, and even when it is available there is no guarantee it will be conclusive enough to distinctly target specific mystical states.

Because psychedelics are non-specific amplifiers and can produce multiple outcomes based on initial conditions of dose, set, and setting, the concept of scanning brains to provide a single unified definition of an expanded state of consciousness may be inherently flawed. Psychedelics can induce trance, catatonia, hallucination, psychosis, paranoia, mania, hysteria, and euphoria all in response to unobservable conditions in dose, set, and setting, so they are demonstrably capable of inducing many complex states of altered consciousness. Psychedelic amplification of perception is observably nonlinear in the form of fractal hallucinations, and the nonlinear amplification of perception is observably tied to size of dose of hallucinogen and strength of incoming stimulus. A model where strong sensory drivers can entrain multistable states of nonlinear psychedelic consciousness is a small extrapolation of these simple observations. Technically, any song or chant produced by a shaman should entrain an organized psychedelic state along a range of chaotic, stable, and multi-stable output. Studying the biofeedback equilibrium effects of spontaneous shamanic vocalization (*icaros*) in a live group setting may be the best starting place for examining tones and frequencies for driving attractor states for each hallucinogen at each dose range. Isolating which songs are best for producing which states at which dose range may ultimately be more of an art than science, relying less on statistical research and more on the shaman's intuitive grasp of all the sliding state variables unique to each psychedelic session.

The conclusion of PIT is that attractors, or multi-stable convergence points in expanded consciousness, do exist, that they are physical in nature, and that when a subject locks into these states they are nothing less than magical. Finding the sweet spots in neural oscillator coherence where consciousness diverges and becomes exponentially complex may be elusive, or may involve different indicators for each individual. General nonlinear dynamics suggests that expanded states of consciousness may be achieved by entraining limit cycles of perception into period doubled bifurcations of normal output, with each period-doubling preceded by some critical sensory stimulus or spiking activity required to drive the phase transition. This driving action also describes the dynamics of entraining stable or self-sustaining limit cycles in a forced Van der Pol oscillator, which is one of the simplest and earliest demonstrations of deterministic chaos in physical systems. Although first applied to electrical circuits, the Van der Pol equation can also be applied to social and theoretical constructs, like species reproduction or the dynamic effects of repetitive marketing on brand goodwill. Mode locking into period doubled or reverse period doubled stability is the general model of state bifurcation in dynamical systems (Fig. 30), though applying a simple nonlinear circuit model to perception raises some processing questions. If perception can jump limit cycles and bifurcate into analyzing multiple simultaneous frames along the order of 3-to-4 times, moving from aliasing 2 frames to 4, and then to 8, and then to 16 simultaneous frames, where does the extra frame aliasing power come from?

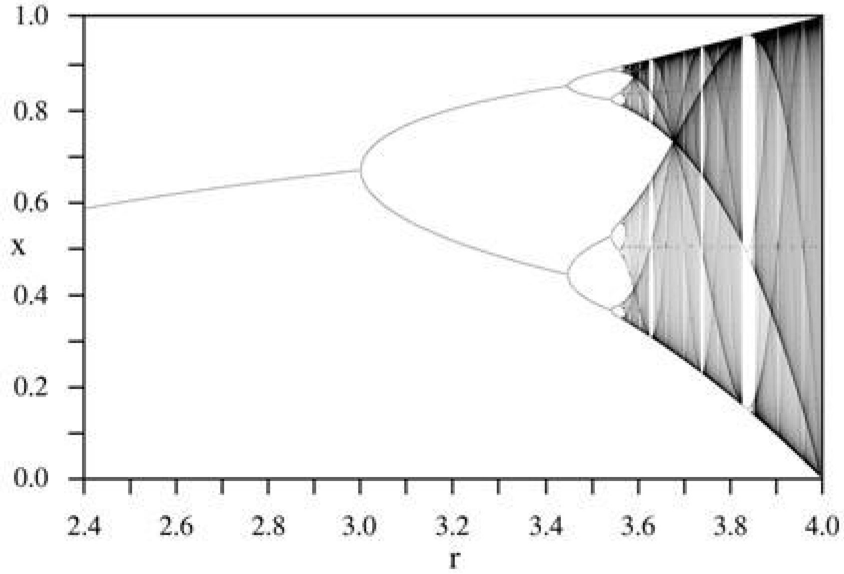

Figure 30. Period doubling bifurcations in the logistics map xn+1 = rxn(1 - xn). The form recedes with self similarity as periods of chaos are followed by periods of convergence and stability. From WikiPedia, Bifurcation Diagram.

The Frame Stacking Model assumes that periodic doubling of frame complexity does not necessarily require a full linear doubling of energy input, but is instead the result of iterated mapping, or nonlinear feedback amplification driving novel re-organization, or phase transitions, through states of chaotic interference and harmonic convergence. For instance, a video camera falling into a chaotic feedback loop does not require extra energy for the transition to stacking multiple receding frames, but the feedback process quickly overwhelms the camera's detail rendering as receding frames over 16 layers deep begin to smooth together in stable interference patterns, or strange attractors, converging on archetypal images of fractal curves, kaleidoscopes, concentric mandalas, galactic vortexes, infinite tunnels, DNA spirals, ascending staircases, and so on (Fig. 24).

Where and how these nonlinear phase transitions occur in human consciousness is still a matter for some speculation. The best evidence indicates that psychedelics promote sensory saturation at the apical dendrite columns of the neocortex, leading to destabilization in recurrent thalamocortical and corticocortical binding pathways. Frame stacking may also be related to receding frame detail being sustained and looped through recurrent circuits between the PFC, basal forebrain, and midbrain. Delaying neutralization or period-doubling saturation intensity in these recurrent mid-brain circuits could lead to frame-feedback or sustained frame echo with high perceived salience. It may seem logical that psychedelic action is localized in the brain, but given the distribution of 5-HT receptors and the indiscriminate nature of ligand binding, it is reasonable to assume that psychedelic amplification in cellular signaling networks is both global and globally coherent. Tracking the physiology of temporal frame aliasing, frame neutralization, frame repetition, and how these sensory mechanisms are exploited by working memory, learning, dreaming, and psychedelics is an area ripe for further exploration.

Finally, the frame model of perception forwarded in PIT is only an approximation of actual perception. While the frame model allows us to put a distinct limit on the rate of human temporal aliasing (roughly 15 frames per second), there is evidence that humans can track multiple moving layers in any single frame. Instead of updating in perfect frames like a film reel, perception is more like a compressed MPEG video or an animation that updates a full keyframe whenever the eyes blink or move, and only makes minor layering changes in between each keyframe. For instance, if you are standing in a grassy meadow watching a bird fly through the air, your brain does not need to update the entire frame of the meadow to track the bird, it only needs to update the layer with the motion of the bird. In this way the brain conserves energy and saves state information for those areas that do not need constant updating, and only updates the entire multisensory frame every few seconds or so, such as when you blink or shift your focus. This motion-sensitive updating of non-essential background noise is most evident in Troxler's fading illusion (Fig. 5).

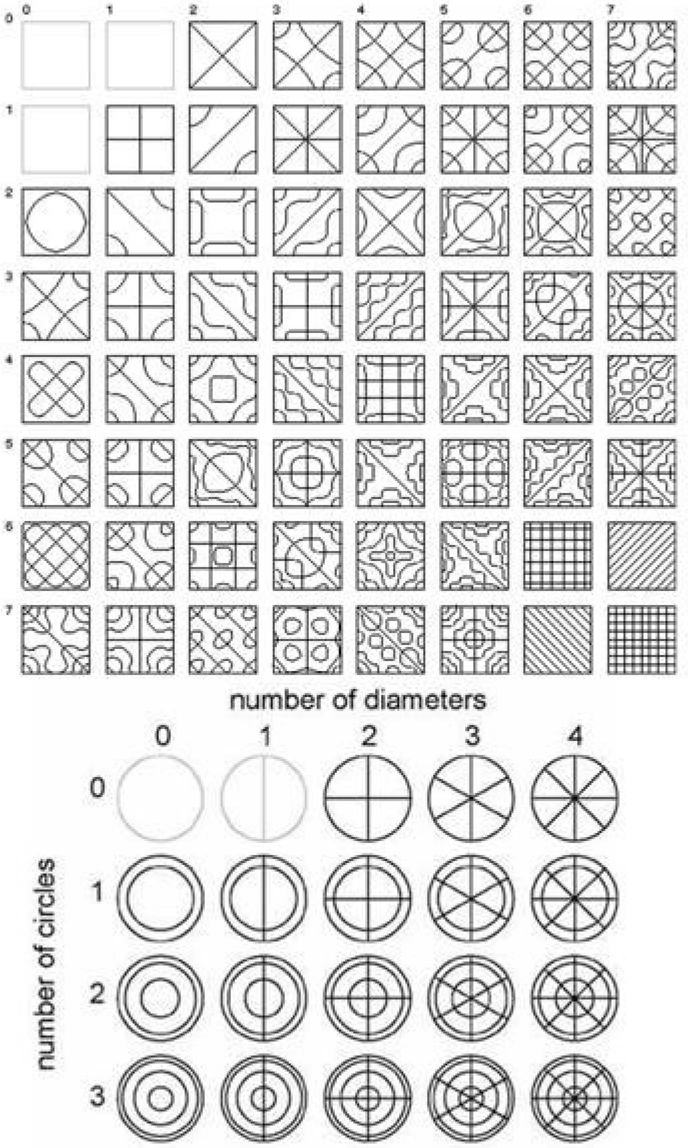

Figure 31. Chladni figures for a square steel plate (top) and a circular plate (bottom) demonstrate the variety of standing wave patterns generated in simple resonating systems. Examining the physical properties of standing waves in resonant systems is also called cymatics. Archetypal forms generated in both rectangular and circular plates are isomorphic of flicker phosphenes seen at various frequencies of light pulse stimulation, and have been reproduced in textile patterns, ceramics, and sacred mandalas since roughly 10,000 BCE. From Lehar, 2010.

Tracking multiple layers for each frame adds another level of complexity to the simplified Frame Stacking Model, and may suggest how psychedelic perception can become kaleidoscopic as radial sections in the visual field mirror themselves, stack, drift, and merge together. Because the update and release of perceptual layers in both multilayered or radial frame filling methods still falls under the classification of temporal aliasing and filling, the general models of PIT would still apply regardless of the morphological or geometric nature of the perceptual bifurcation. The Control Interrupt and Frame Stacking models are provided as very general meta-level descriptions of how psychedelics may subvert temporal aliasing and filling to produce nonlinear feedback and self-sustaining hallucination. While PIT has been focused primarily on visual sensory networks, these models can be applied to the layering and splintering of any subjective sensation of self or reality. The specific pharmacological and neural models underlying these general concepts are more complex than can be detailed in this text, but are sufficiently well understood to make good approximations supporting PIT's claims. Since PIT was designed to be general theory, even as our understanding of perception and pharmacology changes, the general assumptions forwarded here should still apply to all known types of hallucinogenic experience.

Appendix 02

Informal Discussion of Topics

The following is an interview-style discussion of topics presented in *Psychedelic Information Theory* with the author, provided as a summary and general overview of theory for the non-scientific layperson.

What is Psychedelic Information Theory?

The general theory underlying all of PIT is that psychedelics create information when introduced to human neural networks. The spontaneous creation of new information is the essential function of psychedelic activation, and this new information is imprinted into memory and reproduced as music, art, or stories shared with other people. More specifically, PIT presents physical models which describe this generative process, and the dynamics of various psychedelic phenomena like complex hallucination, shamanism, and group mind.

How does PIT describe psychedelic action?

One way to visualize what I'm describing in PIT is through what I call the "Pond and the Pump House" metaphor. Imagine a perfectly round pond with perfectly still water, with a small pump house sitting on an island in the center. When the pump house is turned on it sends out perfectly circular ripples through the water that, over time, create a neatly ordered standing wave of activity. In this metaphor the pond is the surface of the neocortex; the pump house is the body, heartbeat, and respiration; and the ripples are waves of sensory perception seen in an EEG reading of cortical activity. When the pump is on and moving at different speeds, the ripples on the surface of the pond are active and take on different coherent patterns; when the pump is turned off the ripples fade and the pond becomes still and quiet. These are metaphors for consciousness moving from waking to sleeping states.

Now imagine we add a psychedelic to this model. PIT proposes that psychedelics alter the wave patterns of consciousness by creating a tiny tremor under the pond that vibrates the entire structure. Adding the psychedelic to the system creates a competing standing wave that can be seen immediately in the ripples on the surface. The pump keeps pumping, creating its usual standing waves, but because of the tremor there is a new layer of complexity to the ripple patterns. The tremor adds energy to the system, and as it does the standing waves in the pond become more chaotic. Instead of simple coherent ripple patterns, you begin to see overlapping patterns and fast transitions between multiple standing wave states. The complex interference patterns overlap on themselves and exhibit the formal qualities of nonlinear feedback system, such as fractals or cellular automata.

The interference pattern in the ripples of the pond described here is how PIT models a competing tryptamine agonist (a hallucinogen) in the finely timed aminergic system of perception, modulated by serotonin and dopamine. This complex interference pattern is what I am describing with the Control Interrupt Model of psychedelic action. According to PIT, each hallucinogen creates a slightly different tremor or vibration in the signaling pathways of multisensory awareness, which in-turn creates a unique and distinct interference pattern in the standing waves of perception. Some hallucinogenic tremors may be big and rolling, others may be quiet and subtle, others may be sharp and disruptive. The difference in tremor speed and feel created by each psychedelic molecule would be accounted for by the differing receptor affinities and metabolic pathways for each hallucinogen.

How do psychedelic interference patterns relate to the techniques of shamanism and psychedelic therapy?

Let's go back to our pond metaphor. Assume there are sand dunes created at the edges of the pond that correspond to the long-term memory of the standing wave patterns created by the pump house. If you check these dunes after each psychedelic tremor you might find new tiny fractals, spirals, curves, cracks, and filigreed patterns etched into the sand. These sand etchings correspond to the memory of the psychedelic experience now embedded in the patterns of the neural network, and these memory patterns then inform behavior, change beliefs, and are presented over and over again in art, music, and philosophy. That is a metaphor for transformative psychedelic therapy.

Now let's assume there is a tribe of people living at the shores of this pond, and this psychedelic tremor hits once a week. It would be perfectly reasonable to assume that these people would adopt the psychedelic sand patterns as a kind of tribal identity, and embed those patterns into their clothes, tattoos, face paints, pottery, and so on. This is exactly what tribes who take psychedelics do; they embed the colorful fractal patterns created on the surface of their brains onto the surfaces of their bodies, their artwork, their walls, and their world. The physical spilling over of complex psychedelic patterns from a single underlying ripple effect is the foundation of PIT. Psychedelic Information Theory studies the movement of complex information from the genesis of initial hallucinogenic interference pattern to the outward organizing effect on belief, personality, behavior, and tribal structure.

Now, to go one step further, assume that whenever the psychedelic tremor strikes, the tribe of people living at the shores all gather in a circle and begin to sing, or stamp their feet, or beat large drums in unison. The songs produced by the tribe will naturally fall into harmony with the tremor and begin to shape the ripples in the pond through harmonic interference. Over time, if the tribe sings loud enough, they will produce a standing interference pattern, or group hallucination, in the ripples of the pond. This can be described as a shared state of consciousness locked through a standing resonant feedback wave. Shaping interference patterns in consciousness through singing or resonant feedback describes the basic ritual techniques of psychedelic shamanism. Through resonant feedback the shaman and the tribe can master the nonlinear dynamics of the interference pattern to work various forms of magic on the surface of the pond.

The Control Interrupt Model reduces hallucinogenic action to a high speed sensory attack and decay envelope. Why did you decide on that model?

While studying the effects of various hallucinogens, I would always notice a carrier wave, or a high-pitched frequency, or a pulsing, or a throbbing, or a tingling, or some kind of stable interference that was familiar to that substance. And after studying various trip reports for various substances, I realized I was not alone in recording these simple observations. This stable interference is often reported to permeate all sensation; touch, hearing, vision, the entire body. I began to measure the frequencies of these pulses and tingles for different hallucinogens and realized that they all fell into alpha and beta states of consciousness, between 4 to 30 pulses per second, and each drug had a slightly different timing and feel to the way the pulses came on and interrupted consciousness. The slower the interruption, the more of a throbbing or stuttering I felt; the faster the interruption, the more of a tingling, vibration, or high-pitched tremor I felt.

At some point in my analysis of different drugs, I would always say, "That stable interrupt frequency is interesting, I should take a closer look at that," or, "Isn't it weird that I always feel this throbbing on this specific drug, which feels very similar to the pulsing I noticed on this other drug." And then as I began analyzing that one simple pulse interaction, I wondered if pulse interruption in frame perception was all that was needed to produce hallucination. Mind machines produce phosphenes within a small range of light pulse frequencies, so what if hallucinogens did something similar in the same pulse range? What if those pulses were the drug's only action, and the throbbing was the perceptual aggregate of modulatory interference at sensory binding junctions? During the process of formally describing the action of these pulses, it became obvious that the pulsing interference was a carrier wave for hallucination, like the flickering frame rate of an animation reel. The pulses created an overlapping hallucinogenic flicker, or an overlapping modulatory ripple, in multisensory awareness, that creates the chaotic substrate for complex hallucination. It was an extrapolation of psychedelic pharmacology that scaled up to make sense in gross perception, which was the exact kind of model I was looking for.

The more I analyzed the various properties of the flicker or pulsation for each drug, the more I realized that this specific pulsing function was the thing that caused each drug to produce unique geometric hallucinations, like Chladi forms taking on different standing wave patterns on steel plates resonating at different frequencies. I then realized that each hallucinogen could be modeled with a unique interrupt frequency and properties of saturation attack, decay, sustain, and release (ADSR) to describe the onset and feel of distinct hallucinations. An ADSR envelope is a wave modeling technique used in electronic synthesizers to shape the tones and sounds of various musical instruments, but can be used to model the "voice" for any standing wave. The ADSR envelope for each hallucinogen corresponds to receptor agonism and affinity, which naturally shapes the tone and feel of each hallucinogen's unique sensory patterns. After reducing hallucinogenic action to a function of wave interference in perception, it was then only natural to extrapolate hallucination as a cascading event that starts with a small, stable, perturbation in perceptual feedback that grows in amplitude over time to entrain the functional output of the entire system. This model does not rely on anything other than targeted receptor agonism to drive the resulting emergent process.

Why is a wave model of psychedelic action better than traditional shamanic models?

One of the core concepts of physics and science is that every physical interaction can be modeled in discrete packets of energy transfer, and these discrete packets can be statistically interpreted as waves that have formal characteristics of amplitude, frequency, coherence, decay, and so on. This allows a system to be described by predictive physical or mathematical models. Once you break any physical interaction down to a formal wave model, you've essentially described the functionality of the system and can make accurate predictions. Traditional shamanic models are not interested in this level of reductive analysis, but modern science is. PIT fills in some of the formal pieces needed to place techniques of traditional shamanism within the domains of physics and mathematics.

Doesn't reductive analysis take the mystery or artistry out of entheogenic transcendence and shamanism?

There has been a schism in shamanic thought where the drugs have been studied with a reductive pharmacological paradigm, yet the technology of shamanism is still stuck in anthropological or spiritual paradigms. What I am trying to say with PIT is that there is no schism; psychedelic action and shamanism are both fields of physics, they can both be described by physics. This is not a reductive model, it is a unifying model that knits the fields of pharmacology and shamanism together through classical wave mechanics and harmonic theory.

A similar way to look at it might be this. Imagine you were a guitar maker, and you knew precisely how long the neck of the guitar should be, and how tight each string must be, and where each fret must go, and what shape the body should be, all to produce the best and most resonant musical sound. This is an engineering task that can be described by mathematics and harmonic wave theory. However, picking up the instrument and using it to play music that moves people to joy or tears is a process will always be mysterious and artistic. Nothing has been taken away from the artistry of the musician by describing the harmonic theory at the foundation of the instrument. If anything, the harmonic theory allows the guitar maker to produce a better instrument and the musician to attain better mastery.

How do psi phenomenon like telepathy and group mind tie into PIT's harmonic wave model?

You can think of non-verbal communication betweens tribes of humans in terms of group coherence, like the swarming of insects, schooling of fish, or flocking of birds. For most daily interactions we keep ourselves separated as individuals, but for certain activities we drop into a cooperative mode where identity is less important than fluid or harmonic movement within the pack. In humans this can be seen in team sports like soccer or basketball, in the coordinated movements of military squads, in group dancing, or in the intuitive rhythms of lovemaking. Locking into harmonic coherence with another human or group of humans is subjectively felt as nonverbal communication or psi, sometimes reaching the level of telepathy, or instantly knowing what the other person is thinking. Again, this kind of process should not be analyzed within the fields of parapsychology or mysticism. When you're talking about psi and nonverbal communication, you are talking about synchrony and entrainment between resonant oscillators. That is not metaphysics, it is harmonic theory and physics.

Can you describe a resonant oscillator? How does harmonic resonance apply to the brain?

An oscillator is just another term for a wave or vibration, so any system that has a cycling frequency, which is just about everything, is an oscillator. When two oscillators near each other are vibrating near the same frequency they begin to have overlapping wave patterns, or interference patterns, that can be modeled in terms of complimentary synchrony, harmony, phase differentials, and so on. If two oscillators have complimentary interference patterns they are said to be harmonic, meaning they do not dampen each other's power or amplitude. If the two oscillators interfere in a way that drives both of their amplitudes, maximizing the potential energy of the circuit, then they are said to be in resonant coherence. When an oscillating system phase-locks into resonant coherence with another oscillator, energy is amplified and the phase-locked system becomes self-stabilizing and difficult to dampen or perturb even with a competing interference wave.

Harmonic and resonant feedback are at the center of all self-stabilizing oscillating systems, or self-oscillators. Harmonic wave interference conserves energy and is perceived as beautiful to humans in both the arts and the sciences. Loss of harmonic feedback in coupled oscillators drives chaos and chaotic output; resonant feedback and entrainment creates stable attractors and convergence in chaotic systems. These are the fundamentals of all physical systems that oscillate and trade energy over time. If you examine EEG readings it is obvious that the brain is an oscillator with distinct wave patterns for each state of consciousness, and each neuron is a tiny oscillator passing waves of information through an intricately coupled network. So applying the dynamics of resonant oscillators and harmonic wave interference to human perception and expanded states of consciousness is not a radical or fringe idea, it is a natural extension of existing physical theory.

So shamanic singing is a form of resonant feedback for stabilizing consciousness in chaotic psychedelic states?

That is the theory of Physical Shamanism in a nutshell. If you can understand that you can understand almost everything I am modeling with PIT. The interaction starts at the cellular level with a simple pharmacological interference pattern, then erupts into a chaotic ripple across the surface of the neocortex, which then bleeds over into long term memory, informs behavioral changes, and ultimately affects the values of the larger tribe and culture. The chaotic, high-information ripple extends outward over time and goes beyond the confines of the user's mind, expanding into art and media and science and religion and cultural trends. I don't think anyone has ever attempted to deconstruct the entire psychedelic information chain before, let alone attempt to fit it into some kind of physical theory. It is totally new territory.

Clearly, when someone discovers the psychedelic experience they do not keep it to themselves. There is an inherent need to change behaviors and share the experience with others, and that shared experience bounces around the culture and creates resonant interference patterns with shared artwork and reports from other psychedelic experiences, and the amount of detail and spontaneous cultural and tribal organization emerging from this process is enormous. When you attempt to model the psychedelic process with some kind of longitudinal cultural analysis, you see we are dealing with a self-sustaining nonlinear information system that is feeding back on itself through time and producing a disproportionately large amount of output in response to a very small amount of input, which is literally a single pinch of white powder per subject. Somehow, adding that little pinch of white powder ends up changing the world.

Does PIT present a hallucinogenic scale, like the Shulgin scale, which rates hallucination or expanded consciousness along some metric?

The Frame Stacking Model describes degrees of depth and complexity to hallucination, and proposes that depth of hallucination is equal to potency of substance times dose of substance, saturating and feeding back on itself over duration of effect (which is the nonlinear component), modified by the rate of metabolism for that substance. You could write this description as a mathematical formula, but what it is attempting to explain is that there is a critical dose range for each drug where the depth of hallucination becomes self-sustaining and naturally drives towards a fully animated frame rate of about 8-16 stacked frames per second, like an attractor pulling you towards a "peaking" state. If the dose of psychedelic is too small or you metabolize it too quickly, you only get a slightly speedy or jittery sensation corresponding to interference in perception; no peaking state. But once you find the right dose range and achieve self-sustaining hallucination, you lock into this expanded state where you begin stacking progressively animated frames until you top out around 16 receding frames deep. Anything over 16 stacked frames of temporal depth converges towards infinity and overwhelms human perception.

You could break the Shulgin scale down by depth of hallucinogenic frame complexity if you wanted to, but the model PIT suggests is very generic, like a screen saver algorithm or stacked video feedback loop. The Shulgin scale does not attempt to model this kind of complexity in hallucination, nor should it. PIT is attempting to model a more granular level of sensory detail.

You say expanded consciousness tops out at 16 stacked frames? Why 16 frames?

The number 16 seems a bit arbitrary, but it was the number proposed by the person who first described the Frame Stacking Model to me, and this frame depth was upheld to some degree by my own experimentation with mechanical video feedback as well as a variety of hallucinogenic substances. The frame stacking model is an attempt to quantify the fast rate of progressive animation created by hallucination, and to formalize the rate at which sensation saturates, echoes, stacks, regresses, smears, or overlaps into the subsequent perceptual frame. This is a morphological approach to studying the dynamics of progressive hallucination, and you can measure the liquidity or stretchiness of any hallucination based on this metric of seamless smoothing or aliasing between overlapping stacked frames. After about 16 frames of depth, things tend to trail off and blur together into infinitely receding mist.

With the frame stacking model you can step back and analyze your own hallucination and ask; is it flickering and pulsing like a strobe light, or is it oozing slowly with a high degree of fine detail? The more motion trails you are seeing, the more echoes you're hearing, the more liquid and fluid the hallucination seems, all of that corresponds to the number of simultaneous frames you are stacking. After about 16 layers of temporal frame regression, perception begins to saturate and melt and converge down this white spiral or tunnel into infinity. Experiencing this vortex or tunnel, like your mind being sucked out of your body, is a common sensation on large doses of psychedelics. It may be called ego death, or peaking, or whiting out, or a near-death experience, but it is very much like passing out and going unconscious and leaving your body. It is nearly impossible to have any control over thought, action, memory, or behavior past this perceptual capacity. At this point most people lie down and go astral.

How do you think PIT will be perceived in the future?

Most psychedelic theory is built around cultural notions of self and spirituality, and because of this most theories typically have a shelf-life of a few decades. Instead of using metaphors, PIT was built around physical models and the best understanding of the physiology of the brain and perception. This gives PIT a much longer shelf-life than previous psychedelic theory. And since PIT avoids spiritual metaphor it is also applicable across all cultures. PIT is not the final word in the field of psychedelic shamanism, but it provides a neat general framework for the study of expanded consciousness. It is my hope that future generations of explorers will read this text and be inspired to evaluate psychedelic phenomena with a more critical scientific eye.

What experiments can be done to test the various models presented in PIT?

PIT is already a working theory. The process and outcomes of shamanism and psychedelic experimentation have already been formalized and tested. Further testing cannot disprove PIT, but it can help refine the level of detail in the proposed models. PIT was informed by existing research from hundreds if not thousands of different sources, including both published scientific literature, traditional shamanic ritual, and underground research from anonymous psychedelic explorers. PIT does not seek to undo research or suggest further avenues for research, but instead proposes a physical model that can tie all existing research together.

All of the models proposed by PIT come directly from studying subjective reports of psychedelic experience and shamanic ritual, and then overlaying these reports with the most current research on psychedelic receptor interaction along various perceptual pathways. All of the models, methods, and techniques described in PIT have been tested in humans and are accurate. Shamanism is already in common practice with only crude spirit models or psychological models to work with. The only thing left to do is refine our understanding of the brain, and as our understanding grows we can look back at the existing shamanic model and ask, "Is it still accurate?" And if the answer is no, then we need to refine the model and make it more accurate. That's the ongoing labor of science.

About this Text

About Psychedelic Information Theory

Psychedelic Information Theory (PIT) began in 2004 as an extended essay entitled "The Case Against DMT Elves," which was a response to a web article entitled "DMT, Moses, and the Quest for Transcendence" by Clifford Pickover. "The Case Against DMT Elves" was meant to be an antithesis to the "spirit world" models of DMT popularized by Terence McKenna and Rick Strassman in the 1990s, and as such it received some support for taking a more formal approach to examining hallucination. When I realized that the physiological case for complex hallucination had never been sufficiently compiled, I collected some notes and previous writings and began to assemble the PIT Alpha version on the tripzine.com website, which also includes an archive of material from *Trip Magazine*, a journal of psychedelic culture which I published from 1995 through 2005.

The process of putting the PIT Alpha version together took over a year and included the help of many people sending donations, proofreading, and providing valuable feedback on the text. PIT Alpha began as an attempt to reduce psychedelic phenomenology from a purely connective and pharmacological perspective. Sometime in late 2005, halfway through the text of PIT Alpha, I completely abandoned this approach. In 2006 I adopted a circuit model of psychedelic activation I dubbed Signal Theory, which emphasized the role of recurrent excitation in cortical networks as the source of hallucinogenesis. A summary of this theory was presented at the 2006 *Toward a Science of Consciousness* conference in Tucson, AZ. Over a period of two years Signal Theory evolved into what I called the Multi-State Theory of psychedelic action, which was the first time I considered the full implications of psychedelics as catalysts for multi-stable states of nonlinear consciousness.

After releasing a review version of the Multi-State Theory online, I received some interesting feedback that helped focus my thinking, some of it coming from an anonymous Canadian researcher who shared his unique theory of hallucinogenic frame stacking to simplify my theory of recurrent feedback. This led me to study the various nonlinear effects produced by a competing modulator in a precisely timed sequential frame processing system. By extrapolating the various overlapping pharmacological, circuit, and network models of psychedelic action, I settled upon the Control Interrupt Model, which posits that all hallucination begins with a high-frequency periodic interruption of multisensory frame stability that could be described as a wave interference pattern. Once the Control Interrupt Model fell into place, Psychedelic Information Theory suddenly made sense again, and the entire text was rewritten from this new perspective.

After the six year effort on this project, I can proudly say that PIT is the model of hallucinogenesis and psychedelic action I was always seeking to produce. I believe PIT sheds a unique light on the processes of human consciousness and the capacity of the human imagination, and will serve psychedelic research and altered-state exploration for many years. I sincerely thank all of the people who sent donations, feedback, and subtle reminders over the years. Many thanks to all the people who followed my work and kept me focused on finishing, I could not have done it without the consistent support encouragement.

Sincerely,

James L. Kent

About the Author

James L. Kent is a writer and programmer living in Seattle, Washington, and has studied hallucinogens and perception for over twenty years. He is the former Editor of *Psychedelic Illuminations Magazine*, the former Publisher of *Trip Magazine: The Journal of Psychedelic Culture*, and the creator and co-editor of *DoseNation.com*, a web log for drug news, media, culture, and humor. He is also a contributing neuroscience columnist for *h+ Magazine*.

Journey to Paradise

Of Toadstools and Toxins, and A Vivid Tour Of The Heaven (And Hell) That Lies Within Us All

by

Robert Graves

Holiday vol. 32(2):36-37, 110-111, August 1962.

original text: http://www.mushroomjohn.org/graves1.htm

Robert Graves at a cafe in Palma de Majorca, 1954. Photograph: Daniel Farson

Of all the priests and Sunday-school teachers who taught me about Paradise when I was a child, none claimed to have been there. I never dreamed that I would one day enter that Garden of Delights myself, confirm their account in general outline, and return to tell the tale. No: I am not talking in metaphors, nor am I a mystic. Paradise is where I went.

The point of departure was New York City, on an evening late in January. Four friends had gathered in an apartment overlooking the East River, prepared to set out with me under the guidance of our host. The Greeks had a word for his function, namely "mystagogue", meaning a priest who took charge of initiates at the sacred Mysteries of Eleusis, Corinth, or Samothrace. Our mystagogue tonight had advised us to fast beforehand, drink no liquor, avoid sexual congress, clear our consciences and, in fact, try to achieve what the Catholics call "a state of grace". At seven-thirty he prepared us for our journey by giving us a preparation made from the *psilocybe* mushroom. At eight, he began turning out the lights one by one, while we settled down in easy chairs and awaited the revelation. Soon no sound was heard except the swish-swish of cars passing along the Drive: a noise not unlike the sound of waves on a beach.

I felt a numbness in my arms and a pricking at the nape of my neck. In the half-light that filtered through the shutters, colored dots appeared on the ceiling; they shone more when I closed my eyes. We all began to shiver, our pulses slowed down, and a young woman (the mystagogue's daughter) brought in blankets. Since she had already made this journey, we welcomed her reassuring smile and the pressure of her hand. We remembered the mystagogue's warning: "You are going where God dwells, and will be granted all knowledge. … Whoever nurses evil in his heart sees hideous demons and nameless horrors, more proper to Hell than to Paradise, and wishes he had never been born". I anxiously considered my own motives. Would I see demons? Though not a saint, I was at least a dedicated historian and mythologist; with luck I might be spared punishment.

Since even the half-light had become uncomfortably strong for my eyes, I kept them closed. I knew from a study of Celtic and Middle Eastern religion that the road to Paradise often begins under the sea or from a lake bottom, so the greenish water now lapping around me came as no surprise. I entered a marble grotto, passing a pile of massive sunken statuary, and found myself in a high-roofed tunnel lit by brilliantly colored lamps. The sea lay behind.

This was perfect schizophrenia. My corporeal self reclined in a chair, fully conscious, exchanging occasional confidences with friends; but another "I" had entered the tunnel. Could it be the same tunnel through which, four thousand years before, the epic hero Gilgamesh made his approach to the Babylonian Paradise of the goddess Siduri?

Still worrying about the demons, I glanced up at the roof. Thousands of pink, green or yellow faces, like carnival masks, grimaced horribly down; but I dismissed them with a wave of my hand, and they obediently vanished. A turn in the tunnel brought me to the domed Treasury without which no Paradise is complete, whether Hindu, Babylonian, Hebrew, Icelandic, Irish, Greek or Chinese.

Here Majesty's Crown Jewels at the Tower of London would have looked tawdry by comparison with the fantastic treasure now heaped before me: diadems, tiaras, necklaces, crosses, breast-plates, goblets, cups, platters, scepters, blazing or twinkling. But even richer than these jewels were the royal silks spread out for my inspection in blue, mulberry and white: vast lengths miraculously brocaded with birds, beasts, flowers.

My closest experience to this had been in early childhood when, after waiting endlessly in the cold, dark hall, my sisters and I saw the drawing-room door suddenly flung open, and there blazed the Christmas tree: all its candles lighted, its branches glistening with many-colored tinsel.

Still in a trance, I reached for a notebook and wrote: "9 p.m. Visions of …" but got no further: things were happening to fast. Besides, the pen felt strange in my hand, and its scratch on paper sounded offensively loud. I remember saying: "I have seen enough treasure for a lifetime. Is there no human beauty in Paradise?" At once the diadems, tiaras, necklaces, crosses and scepters vanished. Instead, a row of lovely, live, naked Caryatids appeared, lined along the wall, as if supporting the dome. Their faces were shrouded. Yet I hesitated to indulge in erotic fancies, lest the Caryatids should turn into filthy, deformed devilkins like the ones in Flemish pictures of St. Anthony's Temptations. Blushing, I dismissed them, too, and emerged from the tunnel into daylight.

What I had been taught at school and in church proved true enough, though the truth enormously transcended the account. Around me lay a mountain-top Eden, with its jewel-bright trees, its flowers and its pellucid streams. And I experienced not only the bliss of innocence, but also the "knowledge of good and evil". Most Christians understand this phrase as meaning the power to distinguish right from wrong; in Hebrew, however, it signifies a universal understanding of all things, whether good or evil. Indeed, my mind suddenly became so agile and unfettered that I felt capable of solving any problem in the world; it was as if I had immediate access to all knowledge everywhere. Put the sensation of wisdom sufficed - why should I trouble to exploit it?

An unseen voice began singing. I rejoiced that it was a woman's, not a man's. Every original Paradise belongs to a goddess. Eden once belonged to the Great Goddess of Syria. Mother of All Living; but as soon as the Israelites became monotheistic and transferred their allegiance to Jehovah, she was expelled.

The hidden woman, singing in an unintelligible language, scolded, entreated, commanded, coaxed. Every now and then she would change her mood and song; would mourn, triumph or laugh. I fell wholly under her spell and presently enjoyed the curious experience of *seeing* sound. The song-notes became intricate links of a solid golden chain that coiled and looped in serpentine fashion among jade-green bushes: the only serpent I saw in

Eden.

Each song was followed by a pause, and always I waited in a lover's agony for her to begin again, tears stinging at my eyelids. Once she seemed to sing off-key. Perhaps this was quarter-tone music; at any rate, I understood what she meant when I saw one edge of the golden chain formed by the sound spread out into a spectrum, and laughed for pleasure. Toward the end came a quick, breathless cheerful song of creation and growth. The notes fell to earth but rose once more in green shoots which soared swiftly up, putting out branches, leaves, flowers - until this musical plant dominated the sky like the beanstalk in the fairy tale. My spirit followed after into the clear blue air, gazing down on cornfields, fields of poppies and the spires of a heavenly city.

A last the music ended. The visions were fading now. My corporeal self sighed, stretched luxuriously and looked around. Most of the company had left the room. Only one remained. I asked him: "So the journey seems to be over?"

"Ah, but close your eyes, and you can get back at once", he said.

"How do you feel?"

"My mind has never been so clear! Did you ever hear such music in your life?"

We joined the others in the kitchen, ate cold turkey sandwiches and compared notes. "I saw huge slow-moving fish in the sea; did you?" "The demons scared me nearly to death! I wept and sobbed; maybe I wasn't in a state of grace". "Weren't those building *enormous*? But I couldn't place their architectural style." "Me, I'd take the journey all over again - this minute, if I could!"

A girl from the Metropolitan Museum had seen a different Paradise: "I don't know exactly where I went", she said. "It certainly wasn't a garden. But I did see my own kind of visions: blueprints of a simple joy - all difficulties and perplexities unraveled as I watched."

A curious bond of affection had been established between us, so strong that I felt nothing could ever break it. At two o'clock in the morning we said good-bye. By eight I was on my way to Idlewild, headed for Europe, profoundly refreshed and (in Wordsworth's phrase) "trailing clouds of glory" - wisps of celestial memory which persisted nearly a month.

Let me repeat: I am no mystic. Nor were any of my friends. We had visited Paradise by what orthodox Christians, Jews, Hindus and Moslems would call "the back stairs". The sole legitimate approach, they hold, is by humility, asceticism and meditation - a long rigorous discipline for taming one's bodily appetites and intellectual ambitions. Many mystics have visited Paradise, but as a rule, church authorities suspect the humble member who, after severe mortification of his flesh, claims to have seen sights denied his superiors. Mystics attached to no particular church are ignored, unless their ecstasies have caused a breach of the peace; then they are arrested, hospitalized and given shock therapy as schizophrenics. This is their punishment for living simultaneously in two worlds and failing to distinguish between them. Only when mystics write poems or paint pictures in which the paradisal illumination cannot easily be denied - St. John of the Cross, Vaughan, Blake, van Gogh, for example - are they valued as great souls.

While not denying that Paradise can be attained by spiritual discipline (though when this fails the mystic often sees complementary visions of Hell), I suggest that the so-called back stairs to Paradise must one have been its main portal. Others mush have found the entrance as my friends and I had done, by taking an ambrosial drug which conveys mortals to the Otherworld.

Our host and mystagogue that evening was R. G. Wasson, a vice president of Morgan Guaranty Trust and an internationally known expert on mushrooms. He and I had corresponded for some years on the mycophobia, or unreasoning fear of mushrooms, which affects whole populations in Europe, Asia and Africa. Granted, a few mushrooms, easily distinguishable from edible varieties, do contain a mortal poison; but most are palatable if not delicious. Why, we asked each other, when wholesome fruit and vegetables are freely eaten with a sensible disregard for the poisonous or the inedible, should this selectivity be denied to mushrooms? Why were they given disgusting and often obscene names? Why do toads and serpents figure in mushroom folklore? And why, at the same time, should the mycophobic Greeks have had a proverb (quoted by the Emperor Nero) that "Mushrooms are the food of the gods". Were the "nectar" and "ambrosia" of Greek legend perhaps a hallucinogenic mushroom reserved for royalty or priests who, after being granted ecstatic visions by eating it, ranked as living gods? And were *all* mushrooms given disgusting names in order to protect a particular sacred variety from being eaten by the unauthorized?

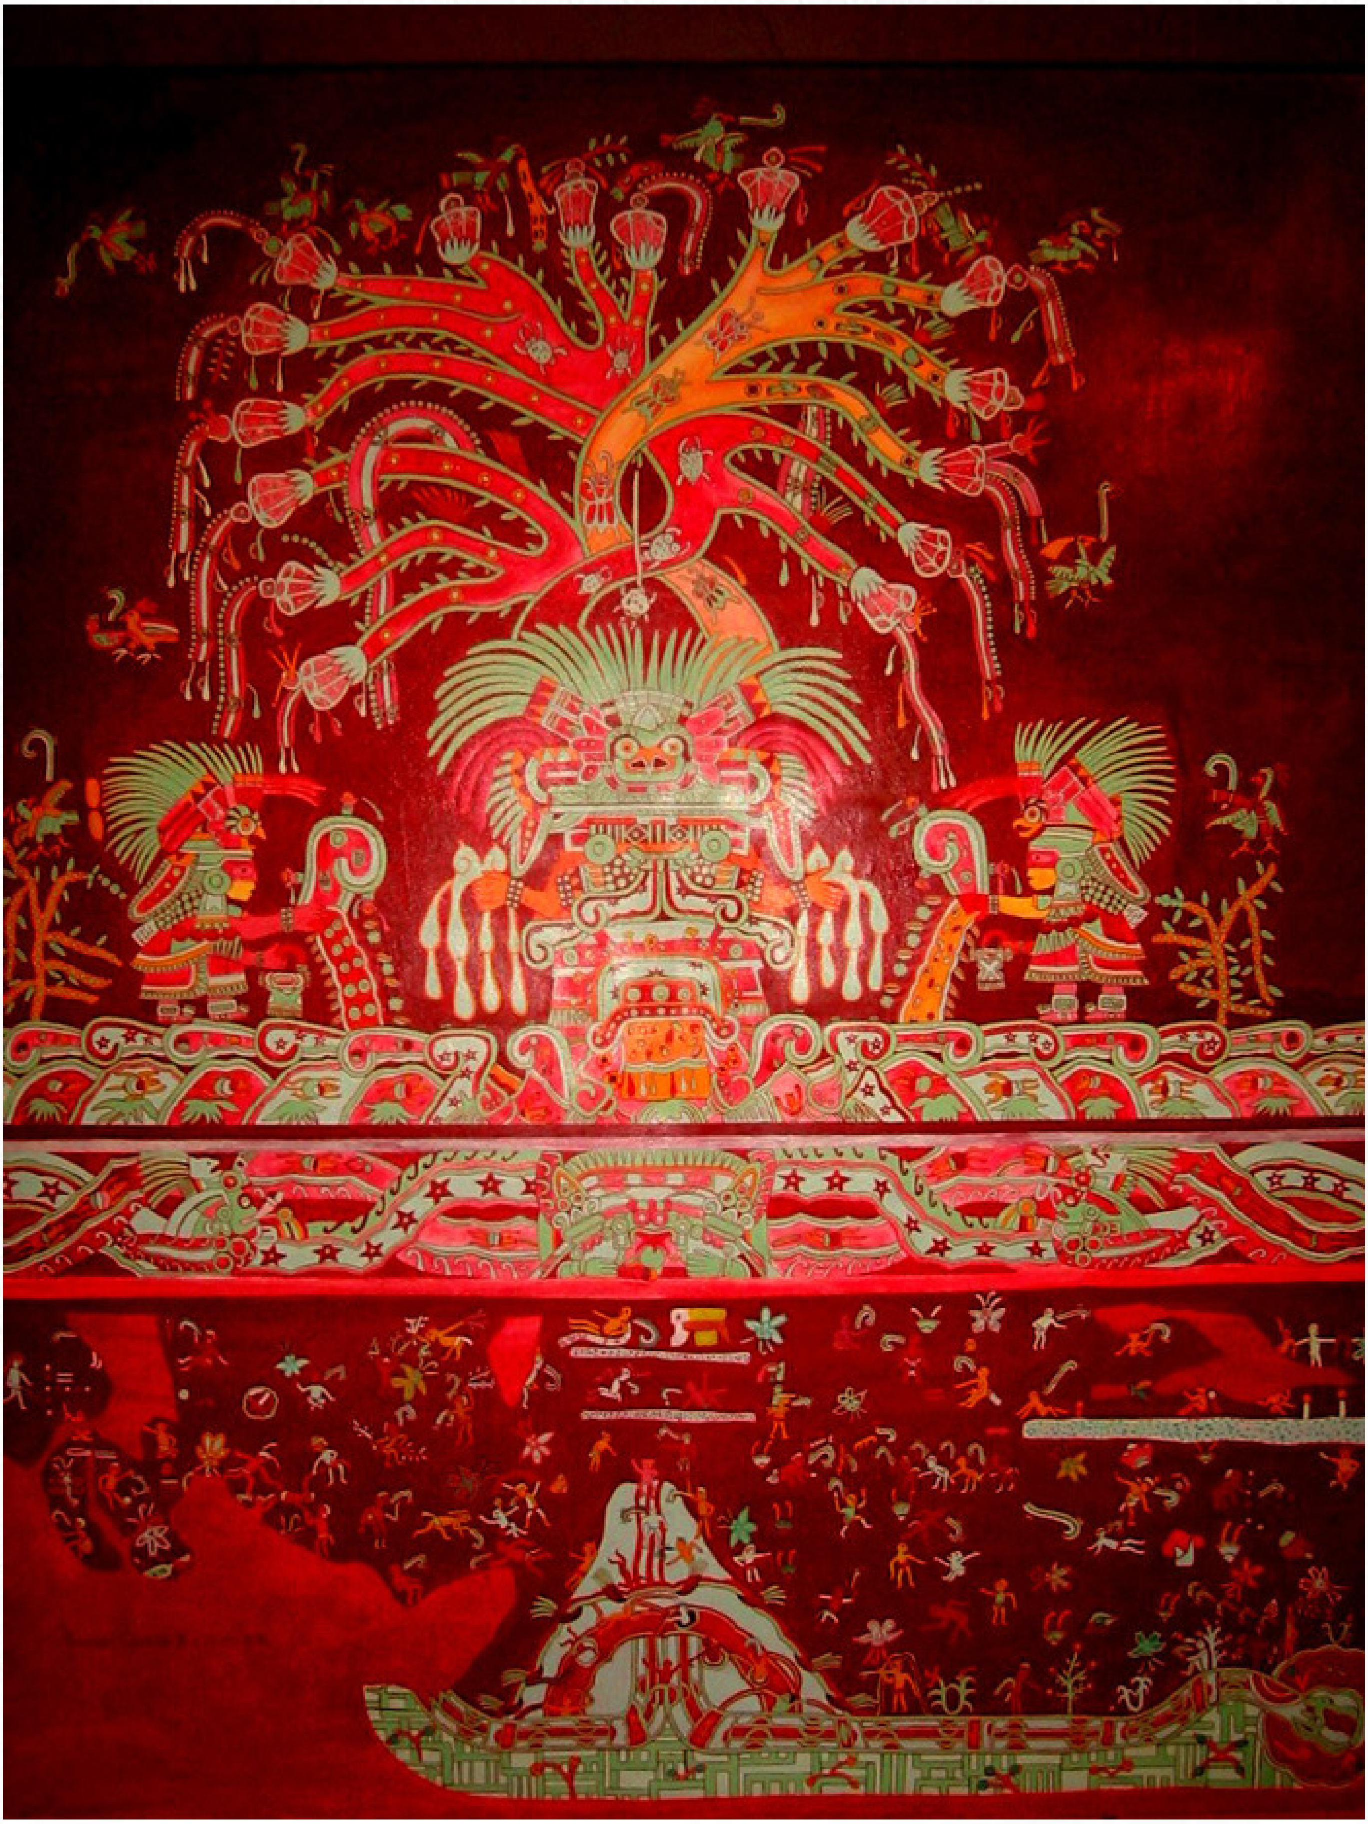
In 1952, I sent Wasson a cutting from an American pharmaceutical journal which seemed to clinch the matter. It referred to 16th Century Spanish reports of an "inebriatory" mushroom eaten by the Aztecs and other Indians of Mexico for oracular purposes. These reports so impressed Wasson that he and his wife, a physician, visited Oaxaca state, where mushroom oracles were rumored to be still operating among the Mazatec Indians. By good fortune they contrived to witness the secret ritual, of which they have published full accounts. During the next five years, Wasson traced the cult in different parts of Mexico, brought back several varieties of sacred mushroom, had them botanically identified by Prof. Roger Heim of Paris and chemically analyzed by Dr. Albert Hofmann of Basle.

That a particular variety of spotted toadstool, the handsome *Amanita muscaria* - in English called "fly-cap" - was used by the primitive Korjaks of Eastern Siberia for inducing hallucinations, we already knew. (So did Lewis Carroll, who made Alice eat it in Wonderland.) Although fly-cap grows freely throughout the American continent, none of the sacred Mexican mushrooms proved to be an *amanita* or to have the same toxic effect. Fly-cap produces a drunken delirium in the eater, accompanied by extraordinary physical strength, erotic energy, and insensitivity to pain; he speaks wildly and loses all sense of time or space. Mexican *psilocybe*, on the other hand - small, bitter and disagreeably rancid - conveys him to Paradise without dulling his wits or turning him into a beast. *Psilocybe* had been our sacred food that evening, though we did not eat the mushrooms themselves; instead, Wasson gave us the last of a small supply of crystals containing their active principle, *psilocybin*, that had been extracted by Doctor Hofmann from a few pounds of mushrooms flown out of Oaxaca. The music which so enchanted us was an invocation to the Mushroom god sung in Old Mazatec by the famous *curandera* (healing woman), María Sabina, which Wasson had recorded on tape.

In Oaxaca, the secret ritual takes place at night, on the mud floor of an Indian hut. Sentries are posted outside against interruption. An altar table is adorned with a crucifix, pictures of saints, and beeswax candles, as well as sacred accessories dating from pagan times - parrot feathers, red flowers, turkey eggs, bark paper, maize kernels, and a pot of charcoal for heating *copal*, a resinous incense. Though the ritual varies between villages, the *curandero* or *curandera* never fails to officiate with profound solemnity, first calling upon God and His saints and passing the mushrooms over the sacred *copal*. They are always eaten raw, in pairs - male and female, originally perhaps representing Tlalóc and his wife - and cups of chocolate or honey-water are served beforehand to keep the empty stomach from nausea. The devotees act with the greatest propriety and must not leave the hut until dawn. Each dose is calculated according to the strength of the mushrooms used, and to the eater's size or known capacity for the drug. No pregnant women or people who have been heard mocking at the mushroom rite may partake of it.

In the Aztec city of Tepantitla there is a fresco dated between the 4th and 7th Centuries A.D. It shows a soul visiting Tlalócan, or Paradise. The expected elements are there: a river (stocked with fish). Bordered with flowers and bejeweled trees, haunted by brightly colored butterflies and a spectacular sky serpent. A blue figure crouches beneath one tree. The soul stands open-mouthed, weeping tears of joy and wonder, his body connected to the river by a thread of water. This river is shaped like a mushroom and, at its source - the center of the mushroom head - lurks Tlalóc, god of mysteries, in toad shape, water issuing from his mouth. The name Tlalóc means "pulp of earth", presumably mushrooms; and Tlalóc, like his mushrooms, was engendered by lightning. He used a seashell as another emblem and owned an underwater grotto. This grotto appears at the bottom of the fresco, marked with a cross, the four head of which are mushrooms. The serpent is Talóc again, who wore a serpent headdress. Spanish missionaries reported infant sacrifices at Tlalóc's annual rain-making rites.

Mazatec Indians now eat the sacred mushrooms as though they were the Christian Host; I even recognized a mention of Christ's name in the invocation. Yet Tlalóc of the Mushrooms till delivers the oracles. The figure crouched beneath the paradisal tree is an *hombrecito* - one of the blue mushroom-spirits who are said to drive thunderclouds through the sky with whips of lightning. Indians describe them as the souls of infants who died before baptism - that is to say, unredeemed pagans.



Tlalócan

May we assume that the similarities between Tlalócan and the Old World Paradises are due to cultural contact, however ancient it may have been, and to a common hallucinogenic food? If so, had Tlalóc a European counterpart who delivered oracles when his flesh was symbolically eaten; who was engendered by lightning;

who possessed an underwater retreat; who had toad and serpent as his emblems; who tolerated infanticide? Yes, indeed: Thracian Dionysus, the Thunderer, may be called Tlalóc's twin. He could transform himself at will and cause extraordinary illusions: as when, captured by pirates, he made a vine sprout from their vessels' deck and twine about the mast, while ivy gripped the rigging, and the oars turned into serpents.

The Eleusinian Mysteries near Athens, in which Dionysus figured, were preceded by fasting and a ceremonial cleansing in the sea. Initiates then entered a temple, drank mint-water, ate pastries baked in magical shapes, and saw celestial visions never to be forgotten. According to the myths, King Perseus of Argos, founder of Mycenae, at first resisted Dionysus. Punished for his obstinacy with an outbreak of madness among the Argive women - they ate their own babies raw, as also happened at Thebes when Pentheus tried to resist the cult - Perseus underwent a conversion and dedicated a temple to Dionysus at Mycenae. Argos had a toad as its badge; and Perseus is said to have named Mycenae after a mushroom found on the site "from which proceeded a stream of water". Perseus even claimed the same sort of nativity as Dionysus: having been engendered by Zeus in a shower of gold. Infanticide is a practice not associated with any Greek myth except that of Dionysus; perhaps both in Greece and Mexico the "babies" eaten in sacred pictures were really mushrooms.

If such mushrooms were, as I suppose, sacred food at the Great Mysteries, they can hardly have been fly caps; though I believe that the primitive Maenads, Centaurs and Satyrs ate these at rowdy autumnal orgies. The Great Mysteries were nothing if not decorous. Nor is any hallucinogenic variety of *psilocybe* known outside Mexico.

Two years ago, however, looking for a clue to the mushroom of the Mysteries, I heard from friends in Portugal that a local witch used a small dung-mushroom to produce visions. I asked them to send a sample to Professor Heim. He identified it as a *Panaeolus papilionaceus*, which grows freely in Europe and North America, and which I had noticed on an ancient Greek vase, shown between the hooves of Nessus the Centaur. I had also read a report on its hallucinogenic properties, published by the American journal *Science* of September, 1914. Fly cap is said to lose its toxic qualities when cooked - I do not guarantee this - but the liquor of *papilionaceus* could have been introduced without detection or loss of potency into the mint-water and sacred pastries at Eleusis.

Fly cap is shown on an Etruscan mirror at the feet of Ixion, ancestor of the Centaurs; and occurs in Guatemalan stone effigies of Tlalóc as toad. It may have been the original "food of the gods" in both hemispheres. My guess is that its properties were first stumbled on in time of famine; and that experiments with smaller, less tempting mushrooms led to the discovery of *psilocybe*, *Panaeolus papilionaceus*, and perhaps other varieties, which also became dedicated to the Toad-god or Serpent-god. Toads excrete a poisonous sweat when ill-treated; serpents have a venomous bite. Both creatures may have served as warning emblems to guard the mushroom taboo.

Any use of hallucinogenic drugs, except for medical purposes, goes against civilized conscience. In this Christian world, only visions won by prayer and piety are ascribed to God; all others are likely to be attributed to the Devil. Because of my Protestant conditioning, I would never take cocaine, heroin, hashish or marijuana, even experimentally; but the Mexican mushroom does not belong to this range of drugs, nor is it habit-forming. So far from stupefying the senses, it quickens them; though the body may be relaxed, the mind stays conscious throughout - indeed, supra-conscious. Since *psilocybe* intensifies and lays bare mental conflicts, an experimentalist is likely to get visions evoked by an uneasy conscience: weeping for grief, not joy, or shuddering aghast. This peculiar virtue of enhancing reality turns the Greek command "Know thyself!" into a practical precept; *psilocybe* illuminates the mind, re-educates sight and hearing.

Paradise thus seems to be a subjective vision. (As Jesus said: "The Kingdom of Heaven is within you". He might have added: "Likewise the Kingdom of Hell".) But the jeweled garden can be attained by the relatively pure of heart without undergoing so austere a discipline as might alienate them from their more worldly friends. The Mexican mushroom feast, for those who attend it in a state of grace and with complete mutual trust - by no means a simple condition - both strengthens human friendship and bestows spiritual enlightenment: the twin purposes of most religions. Yet I should, myself, refuse to enroll in any cult, pagan or Christian, where the mushroom was used as a sacrament - which has happened to *mescalin*, the hallucinogenic drug extracted from cactus buds, now sanctified by a large Christian sect extending from Central America to Canada. Such a cult would not only imply ecclesiastical discipline and theological dogma, but force me into intimacy with people who were not my sort. At school and in the Army I had my share of that.

The fact is that a poetic trance, as I have experienced it on different levels - sometimes light, sometimes so deep that the slightest disturbance caused acute distress - means far more to me than any trance induced by a drug. I understand Coleridge's depreciation of *Kubla Khan*, written almost automatically under the influence of laudanum; he had earned his other poems by active poetic thought. This is not to put an opiate vision, of which one is the dazed victim, in the same class with a mushroom vision, which can be consciously assessed and even controlled; I am aware that under the influence of *psilocybe*, certain oracular *curanderos* and *curanderas* often give amazingly accurate answers to questions asked of them. Nevertheless, Tlalócan, despite its marvels, contains no palace of words presided over by the Living Muse; and no small whitewashed cell (furnished with a table, a chair, pen, ink and paper) where words come to life and combine rhythmically under a poet's supra-conscious guidance. I feel no urge to revisit paradise.

The Philosophy of Psychedelic Transformation

Abstract

Recent scientific research arguably confirms the existence of a remarkable phenomenon: durable psychological benefit to an individual resulting from a single ingestion of a psychedelic drug. In this thesis by publication I ask what exactly is going on in such cases of 'psychedelic transformation'. The thesis is situated in the context of a resurgence of interest in psychedelics within neuroscience and psychiatry, and motivated by the need for philosophical examination of the foundations and results of this research program.

Two common claims in the literature on therapeutic and transformative uses of psychedelics are: (a) psychedelic experiences are a reliable means of knowledge acquisition or spiritual growth, and (b) such epistemic or spiritual benefits are centrally involved in psychedelics' psychological benefits. My aim is to show how such a conception of psychedelic transformation as an epistemic or spiritual process may be reconciled with philosophical naturalism. Naturalism denies the existence of non-natural or supernatural realities such as gods, souls, and immaterial minds. Naturalism is a very widespread view in philosophy today, and is supported by strong arguments.

However, there is a tension between naturalism and the epistemic or spiritual conception of psychedelic transformation, because many psychedelic users claim drug-facilitated knowledge of non-natural realities, such as a mystical 'universal consciousness'. One possible naturalistic response is to dismiss psychedelic users' claims of epistemic or spiritual benefit as mistaken. Here I offer an alternative, showing that we need not throw the epistemic/spiritual baby out with the non-naturalistic bathwater. I show that some kinds of psychedelic-induced epistemic and spiritual benefits are compatible with naturalism and plausibly involved in the drugs' transformative effects.

In 'The Philosophy of Psychedelic Transformation' I review evidence for psychological benefits of psychedelics and defend the claim that psychedelic transformation is unlike standard pharmacotherapies in centrally involving meaningful conscious experiences. I give arguments for three kinds of epistemic benefits: knowledge by acquaintance of the mind's potential, knowledge by acquaintance of the contingency of the sense of self, and revitalised capacities for the acquisition of modal knowledge. In 'The Epistemic Innocence of Psychedelic States' I extend this work, arguing that whatever psychedelics' epistemic demerits, they offer reliable and sometimes unique access to substantial epistemic benefits, including indirect epistemic benefits resulting from psychological benefits. I argue that a balanced picture of the drugs' epistemic merits and demerits is essential to policy discussions about their uses.

In 'Naturalizing Psychedelic Spirituality' I argue that by disrupting mechanisms of self-representation in the brain, psychedelics engender transformative experiences of self-transcendence and mind-expansion which amount to a naturalistic form of spirituality. I propose that such naturalistic spirituality constitutes a viable response to existential anxiety resulting from a naturalistic worldview. Finally, in 'Anatomy of an Avatar: Ego Dissolution in Psychedelic Experiences', I (with Philip Gerrans) argue that such self-transcendent experiences result specifically from disruption to cognitive binding processes implemented by predictive models in the brain. This provides a mechanistic basis for some of the claims of epistemic and spiritual benefit defended earlier.

Declaration

I certify that this work contains no material which has been accepted for the award of any other degree or diploma in my name in any university or other tertiary institution and, to the best of my knowledge and belief, contains no material previously published or written by another person, except where due reference has been made in the text. In addition, I certify that no part of this work will, in the future, be used in a submission in my name for any other degree or diploma in any university or other tertiary institution without the prior approval of the University of Adelaide and where applicable, any partner institution responsible for the joint award of this degree.

I give consent to this copy of my thesis, when deposited in the University Library, being made available for loan and photocopying, subject to the provisions of the Copyright Act 1968.

I acknowledge that copyright of published works contained within this thesis resides with the copyright holder(s) of those works.

I also give permission for the digital version of my thesis to be made available on the web, via the University's digital research repository, the Library Search and also through web search engines, unless permission has been granted by the University to restrict access for a period of time.

Acknowledgements

With standard but nonetheless sincere apologies to anyone I've forgotten, I thank the following people who have been instrumental in bringing this thesis to completion: Gerard O'Brien especially, and Jon Opie as well, for first-rate supervision, and for taking a chance on an unusual and controversial-sounding topic; Philip Gerrans, for inspiration, collaboration, and ongoing casual employment; everyone in the Department of Philosophy at the University of Adelaide, but especially the participants in our cognitive neuroscience reading group: Glenn Carruthers, Simon Eddy, Rob Farquharson, Anastasiya Kravchuk, Michael Lopresto, Andy McKilliam, Matt Nestor, Greg O'Hair, Laura Ruggles, Liz Schier, and Dook Shepherd; Miri Albahari, for timely encouragement; all the courageous researchers and experimental subjects who have played a part in the psychedelic renaissance; all my friends who have helped and supported me over the past four years; and finally, Mum and Dad, for arguing with me about God and raising me on Douglas Adams and Star Trek, both of which I'm pretty sure helped make me the aspiring philosopher that I am.

Introduction

Recent scientific research has arguably confirmed the existence of a remarkable and long-attested phenomenon: durable and beneficial change to an individual's psychological make-up resulting from a single ingestion of a psychedelic drug. What exactly is going on in such cases of 'psychedelic transformation'? That is the central question motivating this thesis.

The renaissance of scientific research into classic, serotonergic psychedelics, such as lysergic acid diethylamide, psilocybin, mescaline, and dimethyltryptamine, has provided evidence relevant to this question, but has not thereby answered all aspects of it directly. In particular, psychedelic subjects frequently claim that their transformation is a direct result of some kind of learning, insight, or spiritual growth. Determining whether psychedelic transformation is essentially an epistemic or spiritual process requires not just empirical research but philosophical analysis of the results of such research. This is so because what counts as 'epistemic' or 'spiritual' is a partly conceptual, philosophical question anyway, and because there are no straightforward entailments of philosophical conclusions by scientific findings; such inferences require synthesis and interpretation of empirical results.

Despite repeated calls for philosophical analysis of psychedelic phenomena, there has as yet been relatively little attention paid in academic philosophy to the renaissance of psychedelic research. The four papers collected here comprise an effort to initiate philosophical discussion of psychedelic transformation. Specifically, they collectively amount to an attempt to reconcile two independently plausible but seemingly incompatible claims. The first of these is philosophical naturalism: the view that the natural world is all that exists, and that there are no non-natural or supernatural entities such as gods, souls, or immaterial minds. The second is the above-mentioned claim that psychedelics are effective agents of knowledge acquisition or spiritual growth.

I call this second claim the 'entheogenic conception' of psychedelics, from the neologism *entheogen* ('generating the divine within') which has been coined to refer to psychoactive substances when used specifically for spiritual purposes (Ruck *et al*. 1979). The tension between naturalism and the entheogenic conception of psychedelics arises from the fact that claims of knowledge acquisition and spiritual benefit consequent upon psychedelic use are often closely tied to non-naturalistic metaphysical claims (e.g. Vaughan 1983). In these four papers I attempt to show that the entheogenic conception of psychedelics is independent of metaphysical nonnaturalism - that there is a plausible and robust conception of psychedelics as agents of epistemic and spiritual benefit that is perfectly consistent with naturalism. I apply a broadly neurophilosophical approach to this issue, examining the findings from psychedelic science and then showing how they support this naturalized entheogenic conception.

In this introduction I begin by describing the phenomenon to be analysed: therapeutic and transformative effects occasioned by psychedelics. I give a relatively detailed description of the phenomenology of psychedelics states, since the psychedelic experience is the fundamental background to my project, and its phenomenology is not described in detail in any of the papers. I then very briefly summarise results from recent psychedelic science, which are described in more or less detail in each of the four papers, before describing the philosophical background to my project. This consists, firstly, of several non-psychedelic currents in recent philosophy which provide thematic and methodological inspiration and context for my arguments, and, secondly, of the few formal philosophical discussions of psychedelic epistemology and spirituality in recent times. Finally, I state the specific aims of each of the four papers and their intended contributions to the overall project.

I think my arguments show that an entheogenic conception of psychedelics is consistent with naturalism and plausible in light of current scientific knowledge. But regardless of the success of these specific arguments, the most general aim of the thesis is to put psychedelic science on the philosophical map. My project functions as a sort of 'proof-of-concept', demonstrating that rigorous philosophical analysis of psychedelic phenomena is both possible and desirable. The four papers collected here show beyond doubt that these controversial and long-neglected substances raise fascinating questions meriting substantial and sustained philosophical attention.

A note on terminology: my main focus in this thesis is 'classic' psychedelics such as lysergic acid diethylamide (LSD), psilocybin (found in 'magic mushrooms'), mescaline (from peyote and other psychoactive cacti), and dimethyltryptamine (DMT, found in various plants and animals.) All of these drugs exert their psychoactive effects primarily by serotonin-2a receptor agonism (Halberstadt 2015). In most cases (though there is some variation between papers) I reserve the word 'psychedelic' for substances of this class, and not other substances such as ketamine, *Salvia divinorum*, and ibogaine, all of which act by different neuropharmacological mechanisms, despite being classified as 'psychedelic' on phenomenological grounds (Sessa 2012).

Psychedelic Phenomenology

What is it like to be intoxicated by a psychedelic? An economical but unhelpful answer would be that psychedelic consciousness is too heterogeneous and ineffable to admit of useful description. It is true that each psychedelic experience is unique, being shaped not just by substance, dosage, and route of administration, but by 'set and setting' - the individual's psychological make-up and the circumstances in which they take the drug. Moreover, psychedelic subjects often say that the intoxication is unlike anything in their prior experience and words cannot do it justice.

However, even if we cannot give necessary and sufficient phenomenological conditions for a psychedelic experience, we can describe some of the more typical effects; certain themes recur in both narrative accounts and more formal quantitative (Studerus *et al*. 2011, Schmid *et al*. 2015) and qualitative (Turton *et al*. 2014, Gasser *et al*. 2015) studies of psychedelic phenomenology. These include alterations of various kinds to sensory experience in all modalities, as well as to thinking, the experience of one's body, space, and time, affect, and the sense of self. It is worth appreciating, though, that detailed and poetic narrative accounts probably come closest to conveying a true sense of what psychedelic experience is like (cf. Durr 1970).

Alterations to vision are a characteristic effect which fall into at least three categories: intensification of stimulus-bound percepts; alteration of stimulus-bound visual experience; and stimulus-independent percepts. The latter can happen with eyes open or eyes closed. In the most dramatic case, visual experience becomes entirely constituted by stimulus-independent imagery, amounting to the apparent experience of a completely different reality.

Aldous Huxley describes the intensification of colour in his famous account of mescaline intoxication: "Mescalin [sic] raises all colours to a higher power and makes the percipient aware of innumerable fine shades of difference, to which, at ordinary times, he is completely blind" (Huxley 1954, 27). Similar intensification can occur to other aspects of vision: shapes, edges, depth and so forth may all seem more clear, vivid and forceful than usual.

Alteration or distortion of stimulus-bound percepts introduces an element of misrepresentation. One common variety of this is objects which are actually stationary being seen as moving or morphing (as in the famous phenomenon of 'walls breathing'); another is for objects to be seen as having shapes or proportions other than their actual ones. Objects may be overlaid with geometrical patterns, stationary or moving, with no apparent basis in the environment (Strassman 2005).

Overlain geometric patterns occupy a middle ground between distortion of stimulus-bound percepts the experience of novel, stimulus-independent percepts. A more unambiguous example of this third category is furnished by a peyote subject who described seeing a "ball of red fire about the size of a golf ball" moving towards him in the room:

> It drifted, swaying a little from side to side, while moving toward me... when the ball of fire had come close enough I poked at its centre with my finger. It then exploded, a lavish shower of multicoloured sparks cascading and dropping on the rug at my feet.
> (Masters and Houston 1966, 7-8).

This fireball and its behaviour were part of the subject's visual experience but seemed to have no basis at all in the objects and events of his environment.

Vivid endogenous visual experience with eyes closed is also very common. The content of such 'closed eye visuals' ranges from simple moving or transforming geometric patterns through fleeting visions of faces, motifs and scene snapshots, all the way to elaborate, immersive and in some cases interactive visual narratives. At high doses, many subjects describe watching and participating in cinematic dramas which seem to constitute allegories of situations in their lives (Masters and Houston 1966). The most extreme case of such visionary experience is when a subject is seemingly transported to a completely different reality or location which is seen in graphic detail with eyes open or closed. In such 'breakthrough' experiences awareness of the actual environment in all sensory modalities is completely lost (Strassman 2001).

Alterations to visual experience are probably more common than changes in other sensory modalities (Strassman 2005). However, with the exception of closed eye visuals (which do not really have analogues) all of these effects can occur in other modalities. Auditory percepts may be intensified, seeming louder (Fischman 1983, 75), clearer, or possessed of more fine-grained detail; appreciation of music is often heightened considerably (Kaelen *et al*. 2015). One subject on psilocybin described hearing his own breathing as though it were the sound of a waterfall (Malitz *et al*. 1960, 10), which seems like an alteration of an existing percept. Novel auditory percepts are sometimes experienced; the peyote subject quoted earlier reported hearing the music that was being played by characters in a vision he observed (Masters and Houston 1966, 9).

Tactile, gustatory and olfactory perception are less notable sites of perceptual changes than vision and audition, although dramatic intensification can occur in these modalities:

> Sensations were acute. I heard, saw, felt, smelled and tasted more fully than ever before (or since). A peanut butter sandwich was a delicacy not even a god could deserve ... To touch a fabric was one's fingertip was ... to experience intense touch-pleasure.
> (Masters and Houston 1966, 10).

Reports of perceptual distortion or novelty in these three modalities are rare. Intensification or apparent enhancement seem to be the main effects of psychedelics on touch, taste, and smell.

Finally, synaesthetic interactions between sensory modalities often occur in the psychedelic state (Luke and Terhune 2013). The most common form seems to be auditory-visual synaesthesia; psychedelic subjects listening to music often find that their closed-eye visuals vary with, and seem to embody, such features of the music as rhythm and tone (Pahnke and Richards 1966, 185).

One's own body can be a significant locus of abnormal experience on psychedelics. Some such experience occurs in one of the five modalities already discussed; for instance, visual perception of one's own body can be intensified, distorted, or embellished with novel percepts. In particular, psychedelic subjects looking at themselves in a mirror often report unusual experiences such as seeing themselves as caricatures emphasising physical features or personality traits, or seeing themselves in the guise of archetypal or mythical figures. Such experiences can also occur in visual perception of other people (Masters and Houston 1966).

Other abnormal bodily experiences also occur. Some subjects report feeling as though their body is heavier or lighter than usual, or more or less near to their conscious mind (which is sometimes felt to leave the body altogether.) Subjects may also report experiencing the transformation of their body into the form of an animal, robot, or other non-human creature, or its shrinkage to microscopic or expansion to cosmic proportions. The body may feel as though it has been transmuted into a different substance, such as glass, or wood (Masters and Houston 1966).

It is also possible to feel as though one is directly experiencing internal physiological processes, such as the circulation of blood, the functions of organs, or the operations of the brain:

> I felt that I could count the beats, the throbbing of my heart, feel the blood moving through my veins, feel the passage of the breath as it entered and left the body, the nerves as they hummed with their myriad messages.
> (Masters and Houston 1966, 10).

As well as alterations to sensory and bodily experience, changes to spatial and temporal awareness are distinctive features of psychedelic states. Huxley claimed his perceptions of space and time were unaltered but his attitudes toward them had changed: he no longer had much interest in either of them (Huxley 1994). Space and time seem to have diminished in salience for him.

More unambiguous alterations to spatial awareness involve changes to perceived distance and relationships: objects appear nearer or further away than they actually are. Subjects who report 'mystical' experiences typically claim to have inhabited a state without any experience of space or time (Pahnke and Richards 1966).

Distortions of temporal perception are very common. Our much-quoted peyote subject described feeling as though he had been smoking a cigarette for hours, then looking down at it to see that the first ash was still on it, implying he had been smoking it for less than a minute (Masters and Houston 1966). Time dilation - the sense that more time has passed than actually has - is far more common than the reverse; which, however, is not unknown. Once again, mystical experiences are a limiting case of alterations to temporal experience: one of the criteria for classifying an experience as 'mystical' is that it involves some sense of eternity or transcendence of time (Griffiths *et al*. 2006).

It is common for the experience of thinking to change dramatically under the influence of psychedelics. Interestingly, many people comparing psychedelics with other drugs remark on how *unimpaired* they find their mental faculties. Huxley again: "The ability to remember and to 'think straight' is little if at all reduced. (Listening to the recordings of my conversation under the influence of the drug, I cannot discover that I was then any stupider than I am at ordinary times.)" (Huxley 1994, 13).

Nonetheless, many psychedelic experiences involve unusual thinking of some kind. Apparent psychological insight is a common example: psychedelic subjects often feel that they comprehend their own personalities, motivations, behavioural patterns and relationships with an unprecedented clarity (Masters and Houston 1966, 185). Thoughts about significant philosophical and scientific questions such as the mind-body problem, the function of the brain, and the meaning of life are also common, even in subjects not predisposed to contemplating such matters (Shanon 2002). Subjects sometimes feel that their thinking is faster or slower, or more or less clear, than usual, and often feel more prone to creative and associative than logical or rational thought (Grof 1975).

Changes to affective experience are a core aspect of the psychedelic state. They mark the fundamental difference between 'good trips' and 'bad trips'. Subjects enjoying mystical experiences experience unparalleled heights of rapture, serenity, and joy, albeit often combined with or preceded by awe or fear (Wasson 1957, Griffiths *et al*. 2006). More intuitively 'psychotomimetic' (psychosis-mimicking) experiences involve equally unparalleled depths of terror, helplessness, and despair (Masters and Houston 1966, 15-17).

Katz *et al*. (1968) made much of their observation that low-dose LSD subjects often displayed an affective ambivalence, consisting of the alternation between or simultaneous experience of mutually antagonistic, if not contradictory, emotions or moods. They suggested that this ambivalence is a central and theoretically important aspect of the psychedelic experience which may explain some characteristics of the more dramatic experiences possible at high doses. The idea that ambivalence or uncertainty is a key aspect of the psychedelic state features in recent theoretical proposals discussed further below (Carhart-Harris *et al*. 2014).

In general, a typical psychedelic experience involving neither a profound mystical rapture nor a terrifying temporary psychosis involves changes to affect which can be seen as analogous to the changes in sense experience: intensification of feelings can occur, as can affective lability (Strassman 1984) - similar to the distortion of existing sensory percepts - and novel, apparently endogenous affective states can occur too: changes in emotion or mood with no obvious environmental trigger or object (Katz *et al*. 1968).

Changes to the sense of self are another core feature of psychedelic experience. Subjects often feel that their sense of individual identity, or the boundaries between self and world, have been altered, loosened, or diminished. As with changes to spatial and temporal experience, this 'ego dissolution' phenomenon reaches its limit in mystical experiences in which the sense of separate individual identity is said to be altogether abolished, replaced by a much larger sense of identity.

Of all the varieties of psychedelic experience, the 'mystical' variety has provoked some of the greatest interest and controversy. Obviously the first question is what exactly a mystical experience is. The category is vacuous if it includes any experience which a subject calls 'mystical' or 'religious', so it needs to be given a more specific definition (Masters and Houston 1966).

The wellspring for academic discussion of psychedelic-induced mystical experience is Walter Pahnke's (1963) doctoral dissertation, which reports the results of the famous 'Good Friday experiment' in which divinity students were given psilocybin in a placebo-controlled study and many more psilocybin than control subjects satisfied criteria for having had a mystical experience. Pahnke based his criteria on the work of the philosopher W. T. Stace (1960) who endorsed the 'common core thesis' (Hood 2006): the claim that mystical experience, despite differences in description and interpretation, has a temporally and culturally invariant phenomenological essence. Pahnke follows Stace in endorsing the common core thesis and offers a phenomenological typology according to which the central features of a mystical experience are: a sense of unity; transcendence of time and space; deeply felt positive mood; sense of sacredness; feeling of objectivity and reality; paradoxicality; and alleged ineffability.

A mystical experience, then, is an experience of a sense of unity transcending time and space, which is felt by the experiencer to be sacred and objectively real, albeit paradoxical and ineffable, and is accompanied by a deeply felt positive mood. Descriptions of such experiences abound in the literature of the world's religions (Huxley 1945). Apart from being induced by drugs, such experiences can be induced by a variety of religious or spiritual practices, or can occur spontaneously.

There has been considerable debate about the relations between psychedelic-induced and non-psychedelic-induced mystical states; are psychedelic mystical experiences 'authentic', or an artificial facsimile of the genuine article? (Zaehner 1958, Watts 1962, Smith 1964). Pahnke's study was an attempt to apply an empirical methodology to these issues. Subjects wrote descriptions of their experiences, and independent observers equipped with Pahnke's typology rated the extent to which each description exemplified each of the elements of mystical experience. Reports of psilocybin subjects, but not of control subjects, overwhelmingly satisfied the criteria, leading to the conclusion that at least some drug-induced states are indistinguishable from spontaneous mystical experiences (Pahnke 1963, Smith 1964).

Pahnke's study had several methodological problems (Doblin 1991). One of the most celebrated results from the new wave of psychedelic research has been a far more rigorous replication of Pahnke's findings by a research group at Johns Hopkins University (Griffiths *et al*. 2006, 2008, 2011, MacLean *et al*. 2011). In these studies, most high-dose psilocybin experiences satisfied criteria for a 'complete' mystical experience. Subjects who had a mystical experience invariably rated their psilocybin session among the five most "personally meaningful" and "spiritually significant" events of their lives, comparing the meaningfulness of these experiences to such things as the birth of a child or the death of a parent (Griffiths *et al*. 2006).

Thus, as well as inducing a characteristic constellation of remarkable changes to sense perception, affect, and the senses of space, time, body, and self, psychedelics are capable of inducing states of consciousness phenomenologically indistinguishable from non-drug-induced mystical experiences. Indeed, Yaden *et al*. (2016) found that respondents to a large-scale survey rated psychedelic-induced mystical experiences as significantly *more* mystical, intense, and life-changing than non-drug-induced mystical experiences.

It is all of these changes to consciousness, and their sometimes durable psychological consequences, that the recent renaissance of psychedelic science seeks to understand.

Psychedelic Science

The new wave of psychedelic research has sought, among other things, to reassess earlier claims made in the 1950s and 60s for the therapeutic and transformative effects of this class of drugs, but with higher standards of methodological rigour. Importantly, supervised psychedelic administration in controlled research conditions has been shown to be quite safe in both healthy volunteers and patient populations (Johnson *et al*. 2008). Various small pilot studies have found preliminary evidence for the alleviation of symptoms of depression, addiction, and anxiety lasting several months after just one or two psychedelic experiences (dos Santos *et al*. 2016a, Garcia-Romeu *et al*. 2016). More recently, two larger, double-blind randomized controlled trials have found further evidence for the efficacy of psilocybin in alleviating psychological distress relating to terminal illness (Griffiths *et al*. 2016, Ross *et al*. 2016).

Studies in non-patient populations have also found that psilocybin can induce mystical experiences causing positive personality change lasting over a year in a majority of healthy volunteers (Griffiths *et al*. 2006, 2008, 2011, MacLean *et al*. 2011). Subjects who had mystical experiences rated their psilocybin sessions as among the most personally meaningful and spiritually significant events of their lives. More recently, a smaller study found that a single LSD session caused similar personality changes in healthy volunteers lasting at least a fortnight (Lebedev *et al*. 2016).

Besides studies of therapeutic and transformative effects, much basic research has been carried out aimed at identifying the precise nature and mechanisms of psychedelic effects. Numerous animal and human studies have probed the molecular mechanisms and effects of psychedelics on intracellular signalling, on behaviour, and on measures of neuropsychological function and cognitive processes such as attention, working memory, visual and emotional perception, and creativity (Halberstadt 2015, Nichols 2004, 2016).

One of the most interesting lines of research in the psychedelic renaissance has been the use of modern neuroimaging technologies to probe neural correlates of psychedelic consciousness alteration in humans (reviewed in dos Santos *et al*. 2016b). Positron emission tomography (PET) studies of mescaline and psilocybin in the 1990s consistently found increases in glucose metabolism concentrated in frontal brain regions, suggestive of a pattern of metabolic 'hyperfrontality' in the psychedelic state (Hermle *et al*. 1992, Vollenweider *et al*. 1997).

This finding has since been challenged by functional magnetic resonance imaging (fMRI) studies of the psychedelically intoxicated brain. Carhart-Harris *et al*. (2012) reported that acute intravenous psilocybin administration caused decreases, rather than increases, in neural activity as measured by blood-oxygen-level-dependent (BOLD) signal. Moreover, these decreases were localised to nodes of the Default Mode Network (DMN), a functionally coherent network of brain regions repeatedly implicated in mind-wandering, autobiographical memory, and various aspects of self-reference. Subsequent fMRI studies of psychedelics including LSD and ayahuasca have not replicated all the findings of Carhart-Harris *et al*., but decreased BOLD signal in DMN hubs is a frequent result.

The discrepancy between the fMRI and PET results remains to be explained. Various solutions have been proposed. Carhart-Harris *et al*. (2012) suggested that it might be due to the different time courses of oral vs. intravenous psilocybin intoxication, as well as differences in the temporal resolution of the imaging technologies used - but fMRI studies of the DMT-containing psychedelic beverage ayahuasca, which has a similar time course to oral psilocybin, also found decreases rather than increases in signatures of neural activity. Another possibility is that the BOLD signal measured by fMRI tracks neural synchrony, rather than activity, and the psychedelic state is characterised by decreased synchrony but increased activity in key hub regions (Halberstadt 2015). It is safe to say that more research in this area is required.

Such unresolved issues notwithstanding, fruitful and intriguing theoretical proposals have been made on the basis of the recent spate of fMRI results. Citing their findings that psychedelics increase the unpredictability and diversity of patterns of functional connectivity in the brain, as quantified by the notion of entropy, Carhart-Harris *et al*. (2014) proposed that psychedelics induce a highly entropic state of consciousness by destabilizing key connector hub regions whose activity ordinarily functions to constrain the quality of cognition, orchestrating and coordinating the activity of many large-scale networks to ensure that cognitive resources are directed towards adaptive goals. Speculations about the mechanisms of psychedelic therapy have focused on the idea that by this kind of method, psychedelics can break down entrenched and maladaptive patterns of thought and behaviour, creating a period of greater flexibility from which the cognitive system can re-form into more adaptive patterns (Nichols *et al*. forthcoming).

Despite many open questions concerning functional neuroanatomical details, this broad perspective according to which psychedelics disrupt systems involved in self-reference, leading to temporarily 'unconstrained cognition' with potential therapeutic benefits, sits comfortably with the phenomenology as described earlier, and has formed the basis for many of my arguments in this thesis. I turn now to the non-psychedelic philosophical background to my project.

The Philosophical Background

In recent decades philosophy of science has taken a turn towards recognition of the heterogeneity of science and analysis of the specific and distinctive methods and explanatory strategies deployed in the various special sciences (e.g. Craver 2007, Ross 2014, Sober 2000). Despite the extensive literature on ethical issues relating to drug use, especially for non-medical reasons, psychopharmacology as a discipline has received relatively little attention from a philosophy of science perspective. The notable exception is Stein's (2012) pioneering volume, which discusses conceptual, explanatory, and methodological questions relating to how we classify and categorise drugs and how best to understand their effects on cognition, consciousness and the self (as well as discussing relevant ethical issues.) However, Stein only mentions psychedelics in passing.

A few recent publications suggest that interest in philosophy of psychopharmacology is increasing (e.g. Aragona 2013, Cavanna 2015). The renaissance of psychedelic research constitutes a golden opportunity for this nascent field. All sorts of interesting conceptual and methodological questions are raised by psychedelic science. For instance, given the dramatic acute and long-term effects of psychedelics on mood and behaviour, psychedelic therapy seems like an ideal case study for recently influential ideas about multi-level mechanistic explanation in the life sciences - an issue touched on in the first paper of this thesis. Moreover, there are methodological questions about how to test for therapeutic effects of an intervention for which adequate blinding is difficult if not impossible (Langlitz 2012). In general, recent trends in philosophy of science suggest a need for more philosophical analysis of (psychedelic) psychopharmacology.

Another part of the philosophical context in which my project is situated is the recent spate of interest in re-evaluating the epistemic status of intuitively suboptimal cognitive conditions and processes. There is a long history of philosophical distrust of non-ordinary states of cognition and consciousness, and a tendency to see such conditions not only as highly dubious sources of knowledge, but as positive threats to knowledge (Windt 2011). This tendency is understandably more pronounced in the case of conditions which clearly are attended by obvious psychological or epistemic costs, such as delusion, confabulation, and implicit bias. And the undeniable detrimental psychological effects which can sometimes result from psychedelic experience, combined with the conception of psychedelics as 'psychotomimetic' or 'hallucinogenic' - that is, essentially epistemically detrimental - substances would seem to place psychedelic states squarely in the camp of epistemically bankrupt consciousness alterations.

However, recently a number of philosophers have been arguing that the epistemic status of such 'imperfect cognitions' merits re-evaluation. The literature on 'epistemic innocence' proposes that even cognitive conditions with undeniable epistemic costs sometimes lead to significant and otherwise unavailable epistemic benefits (Bortolotti 2015a, 2015b, Bortolotti and Miyazono 2016, Sullivan-Bissett 2015). In many cases, the argument is that these cognitive conditions can lead to psycho-emotional benefits, and epistemic benefits result from those, since knowledge acquisition is often dependent upon adaptive psycho-emotional functioning. The scientific reassessment of the potential of psychedelics to cause lasting psychoemotional benefits suggests that psychedelic states ought to be subjected to the same kind of epistemological re-evaluation. Moreover, the many distinctive aspects of psychedelic therapy, including frequent claims of epistemic benefit by subjects, mean that the analysis of psychedelic phenomena may have implications for this broader project.

The growing interest in how to tackle the existential anxiety and 'disenchantment' resulting from a naturalistic worldview is another recent philosophical current which is relevant to my concerns here. It has long been appreciated that the transition to a post-religious naturalist metaphysics often evokes anxiety about the absence of traditional foundational sources of meaning. Recently, it has been suggested that this existential crisis is filtering into the broader culture and becoming more acute due to the revolution in the self-image of humankind brought about by advances in contemporary neuroscience (Flanagan and Caruso forthcoming, Metzinger 2009). How to individually and collectively come to terms with this 'neuroscientific turn' in the image of humankind is arguably one of the most urgent philosophical challenges of our age, connecting with a classical Socratic vision of philosophy as concerned with the art of living.

The capacity of psychedelics to induce intense and meaningful transformative experiences immediately suggests their potential relevance to this issue. What is more, there has recently been a spate of philosophical interest in the related project of 'naturalizing spirituality' (Stone 2012). This literature is based on a recognition that the term 'spirituality' can legitimately be used to refer to a kind of personal quest for meaning and transcendence that is in principle independent of traditional religious belief. The question whether such a quest can be undertaken in the spirit of naturalism is interesting and important. Plausibly, something like naturalizing spirituality may form part of a viable response to the 'neuroexistentialist' anxiety resulting from the naturalistic disenchantment of the world. Psychedelic subjects' frequent tendency to describe their experiences as 'spiritual'suggests that an analysis of psychedelic phenomena may help to address some of these issues.

Finally, recent philosophy of mind has taken a distinctly empirical orientation, looking to data from neuroscience and psychiatry to inform its theorizing. This trend is most clearly exemplified in the interdisciplinary enterprise of 'philosophical psychopathology' (Graham and Stephens 1994), which treats observations from the study of psychological disorder as a crucial source of information about the structure of the mind in both normal and abnormal conditions. One of the key concerns of scientifically and psychopathologically informed philosophy of mind has been the nature of self-awareness, a central and ubiquitous mental phenomenon that undergoes sometimes bizarre transformations in altered conditions of psychological functioning (Stephens and Graham 2007, Metzinger 2013). Moreover, such conditions may even offer useful clues to the nature of phenomenal consciousness itself (Brogaard and Gatzia 2016).

The neurophilosophy of self-awareness and consciousness has hitherto drawn on whatever sources have been available, including, to some extent, the study of psychedelics (Metzinger 2003). But the ever-increasing body of new knowledge about psychedelic-induced alterations to consciousness and self-awareness has perhaps not yet been fully philosophically appreciated or exploited. The empirical turn in philosophy of mind is yet another recent development which justifies a detailed philosophical investigation of psychedelic phenomena.

Philosophy of Psychedelics

As I have mentioned, relatively little explicitly philosophical attention has been paid to the psychedelic renaissance. However, that is not to say that none has. I will now describe the few philosophical discussions which are directly relevant to my project of naturalizing the entheogenic conception of psychedelics, before stating the aims and intended contributions of each of the four papers in the thesis.

Benny Shanon is a cognitive psychologist with a philosophical background who has conducted extensive research on ayahuasca. His monograph *The Antipodes of the Mind* (2002) is a landmark work of psychedelic phenomenology. But Shanon has also explored some of the philosophical issues raised by the psychedelic experience.

In his paper 'The Epistemics of Ayahuasca Visions' Shanon (2010) assesses psychedelic subjects' claims of knowledge acquisition from an avowedly naturalistic perspective. He argues that psychedelics (ayahuasca, in particular) can allow a subject to attain therapeutically valuable psychological insight into their own and others' minds and the human condition. This claim is echoed by Metzinger (2003) whose primary concern is the use of psychedelic data to inform theories of self-awareness. Nonetheless, he notes that the apparent therapeutic efficacy of the drugs is readily explained by the hypothesis that they can in fact facilitate valuable insights.

Shanon proposes that other putatively epistemic benefits are accessible by means of psychedelic experience. One of these is the apprehension or appreciation of truths about nature in new and deeper ways that are comparable to the kinds of distinctive and insightful conceptions of things communicated in great art.

Other kinds of epistemic benefits mentioned by Shanon include increased well-being and stamina; more harmonious social interaction; novel solutions to problems in one's field of specialisation; and enhanced abilities of artistic performance and creativity. It is an interesting conceptual question to what extent each of these proposed benefits merits the appellation 'epistemic'.

Shanon says a little about the means by which he thinks ayahuasca-induced visions impart these kinds of knowledge. One is the direct impact of the visions themselves, which are extremely beautiful; merely experiencing such beauty causes a profound affective response leading to changes in attitude and outlook. Sometimes subjects experience visions of entities who instruct them directly; for example, about their field of specialisation. In other cases, vivid visions of past (actual) and future (hypothetical) situations in a subject's life enables them to see abstract features and commonalities of these, particularly when sequences of such scenes are presented juxtaposed in thematic rather than chronological ways. Further, interactive visions can function as a kind of virtual reality, by acting in which a subject can learn problem solving strategies and other things learnable by acting in the real world.

Albeit not explicitly cast in terms of knowledge or spirituality, it is also worth mentioning the work of Kenneth Tupper, an education theorist who analyses the cognitive enhancement potential of psychedelics in a way that seems consistent with naturalism. Drawing on the work of philosophers and education theorists, Tupper (2002) proposes that psychedelic experiences can be a means of accessing "mythic and somatic forms of understanding" that are neglected in contemporary educational practice, and also that they can be a means of increasing a hypothesised "existential intelligence" (Tupper 2003). Thomas Roberts (2013) is another education theorist who has extolled the potential cognitive benefits of psychedelics.

On the other side of the debate, G. T. Roche (2010) critiques the claim that psychedelics can induce epistemically or spiritually beneficial experiences. His two basic grounds for scepticism are that psychedelics disrupt the functioning of the cognitive mechanisms which allow the brain to represent reality accurately, and that drug-inspired claims need independent justification to count as knowledge.

Many of Roche's arguments specifically target putative non-naturalistic knowledge gained from psychedelic states and are therefore irrelevant to my concerns. But he argues that even the potentially naturalistically palatable claim that psychedelics can induce veridical apprehensions of oneness with the universe is untenable because the idea of experience without a subject is contradictory. He also argues that psychedelics cannot reliably yield moral or existential insight, because many putative such insights seem flippant, amoral, or otherwise objectionable, and says that there is no good evidence that psychedelic experiences can lead to scientific insight. Such experiences, for Roche, involve radical distortions of cognition and perception which are obviously inimical to such insight. He also argues against the claim that psychedelics can induce mystical experiences equivalent to non-drug-induced ones.

Against the background of these discussions, here are the aims and intended contributions to the overall project of the four papers in this thesis. In the first paper, 'The Philosophy of Psychedelic Transformation', I begin by arguing for the importance of a rigorously naturalistic philosophical analysis of psychedelic phenomena. I then combine scientific evidence concerning the benefits of psychedelics with ideas from philosophy of science to argue that psychedelic transformation is a distinctively humanistic drug therapy because its mechanism of action involves conscious mental representations. I further suggest that this meaning-involving therapeutic mechanism has epistemic dimensions. Establishing the consciousness- and meaning-involving nature of psychedelic transformation is a prerequisite for naturalizing the entheogenic conception of the drugs, and arguing for epistemic dimensions in psychedelic therapy contributes to this project directly by specifying plausible naturalistic epistemic benefits which are consistent with scientific knowledge about transformative mechanisms.

In the second paper, 'The Epistemic Innocence of Psychedelic States', I extend these efforts by arguing that psychedelics can induce additional epistemic benefits as a consequence of their psychological benefits, and moreover that their epistemic benefits - both direct and indirect - are sometimes not available by any other means. The aim here is to further develop the naturalistic grounds for seeing psychedelics as agents of epistemic benefit, and also to connect these ideas to broader discussions about the epistemic innocence of 'imperfect cognitions'. I emphasize the relevance of these conclusions to policy discussions about psychedelic use.

In the third paper, 'Naturalizing Psychedelic Spirituality', I argue that the beneficial effects of psychedelics on existential distress in terminal illness suggest that these drugs may offer the way to a solution to the neuroexistential anxiety accompanying the naturalistic turn in the image of humankind. I connect this proposal to recent philosophical discussions of naturalized spirituality and argue that many of the transformative aspects of psychedelic states which lead subjects to call them 'spiritual' are independent of non-naturalistic metaphysical apprehensions. This amounts to a naturalistic vindication of the specifically spiritual aspect of the entheogenic conception.

Finally, in the fourth paper, 'Anatomy of an Avatar: Ego Dissolution in Psychedelic Experience', I (with Philip Gerrans) argue that the ego dissolution experiences occasioned by psychedelics can best be explained as a disruption to mechanisms of cognitive binding (i.e. representational integration) which give rise to the experience of self-awareness in ordinary waking consciousness. This contributes to naturalizing the entheogenic conception by vindicating the idea that ego dissolution, a core element of spiritual psychedelic experiences, amounts to a veridical apprehension of the non-existence of a durable substantial self. It also provides a plausible mechanism for many of the pro-epistemic and pro-spiritual qualities of the psychedelic experience in the form of detaching attention and salience from their usual coupling to personal concerns, goals, and agendas.

Many questions remain, and I will mention these in the conclusion section at the end. But in these four papers I will show that despite arguments to the contrary, the idea of psychedelics as agents of epistemic and spiritual benefit is alive and well in light of the recent renaissance of research.

The Philosophy of Psychedelic Transformation

Statement of Authorship

Title of paper:	The Philosophy of Psychedelic Transformation
Publication status:	Published
Publication details:	Letheby, C. (2015). The philosophy of psychedelic transformation. Journal of Consciousness Studies 22, 170-193.
Principal Author	
Name of principal author (candidate):	Christopher Letheby
Contribution to the paper:	Devised the arguments and wrote, proofread, polished, formatted, and submitted the paper.
Overall percentage (%):	100%
Certification:	This paper reports on original research I conducted during the period of my Higher Degree by Research candidature and is not subject to any obligations or contractual agreements with a third party that would constrain its inclusion in this thesis. I am the primary author of this paper.
Signature:	
Date:	

Introduction and Methodological Preliminaries

Psychedelic drugs are remarkable substances which have been hailed as indispensable epistemic instruments for the sciences of mind, as unparalleled psychotherapeutic interventions, as unique sources of insight into the nature and genesis of psychosis and religion, and as keys to the survival and flourishing of the human species (Osmond 1957, Sessa 2012). After a politically-driven decades-long hiatus, scientific study of these drugs in humans has resumed with impressive results. Given the magnitude and variety of significance ascribed to the substances, it is surprising that philosophers have not shown much interest in this 'psychedelic renaissance'

Here I aim to remedy this deficit. Recent philosophical work on psychopharmacology focuses on bioethical questions of authenticity and autonomy with respect to enhancement (Parens 2005, Glannon 2008, Stein 2012). As such, this is a natural place to begin philosophical analysis of psychedelic phenomena. The psychopharmacological enhancement literature is driven by a concern that certain psychopharmacological interventions may be dehumanising or may compromise the authenticity or identity of patients. Without committing myself to the view that other drugs do compromise authenticity, I want to explore the notion that psychedelics respect authenticity in a unique way - by involving the person in a transformative process which is somewhat[1] transparent, rational, and meaning-involving.

This is similar in spirit to contrasting utopian and dystopian views of psychopharmacology which the philosopher M. H. N. Schermer (2007) finds in the work of Aldous Huxley. In Huxley's novels, fictional psychedelic-like drugs are depicted as humanising and empowering while fictional non-psychedelic-like drugs are depicted as dehumanising and disempowering (Huxley 1932, 1962). I am not committing myself to the dystopian view of non-psychedelic drugs, but exploring the possibility that psychedelic drugs have uniquely utopian credentials. My conjecture is that this difference arises from the fact that psychedelics engage the self in a humanistic transformative process which is (somewhat) transparent and meaning-respecting, rather than performing sub-personal surgery on the constituent parts of a passive self.

I begin by briefly reviewing the history and phenomenology of psychedelics, and recent evidence for therapeutic and transformative efficacy. Next, I discuss my conjecture about the meaning-involving nature of psychedelic transformation. This conjecture depends on the empirical claim that the altered state of consciousness (ASC) induced by psychedelics is causally relevant to the long-term benefits caused by the drugs. I discuss four lines of evidence for this claim - three briefly, before spending longer on the fourth, which draws on recent neuroscientific studies of psilocybin. This research has been claimed to support a theory of psychedelic transformation which implicates the ASC. I describe this theory and argue that it not only implicates the ASC in the transformative process, but supports the idea that psychedelic transformation is an epistemic process. It is tempting to assume that psychedelics are fundamentally agents of misrepresentation (as suggested by the popular term 'hallucinogen'.) From this perspective, one might think that whatever psychedelic therapy is, it is not a process of knowledge acquisition. I suggest this is too quick, and there are good reasons to think that psychedelic experience can sometimes lead to knowledge gain.

Before I begin, some methodological preliminaries are in order. Here I take a naturalistic approach to the phenomenon of psychedelic transformation. Naturalism is a contested term in contemporary philosophy but minimally is taken to mean a rejection of supernatural entities or realities, and an acceptance that everything which exists forms part of a closed causal system populated by the kinds of entities and properties studied by the natural sciences (Papineau 2009). Many psychedelic experiences - especially profoundly transformative ones - involve the apparent apprehension of non-naturalistic realities, and many subjects believe these apprehensions are veridical (Masters and Houston 1966, Shanon 2002).

Given the preceding observation, why take a naturalistic approach? Firstly, naturalism may well be true. There are strong arguments in its favour which convince most current philosophers of mind that some version of it probably is true (Horst 2009). And if naturalism is true, the correct account of psychedelic transformation is naturalistic. Secondly, if naturalism is false, we can establish this only by reaching its limits. The principle of parsimony (Ockham's Razor) dictates that we posit only what is necessary to explain a phenomenon. This raises the question: what could establish the necessity of positing non-natural realities to explain psychedelic phenomena? The answer, I submit, is: trying, and failing, to explain such phenomena solely in terms of the independently well-motivated naturalistic posits already available to us. Cognitive neuroscience is an interdisciplinary attempt to explain mental phenomena - including consciousness - naturalistically. Its total success or partial failure remains to be seen. But the cognitive neuroscience of consciousness is in its infancy, and presuming its eventual partial failure at this point would be premature[2]. So considerations of parsimony dictate that we assume, at least for the present, that psychedelic consciousness can be explained naturalistically.

There is another good reason to try to naturalize psychedelic transformation. The modern West is unusual among human societies in lacking socially approved ritual techniques for the deliberate induction of altered states of consciousness (Bourguignon 1973). Given the apparent safety and possible benefits of long-term ritual psychedelic use (e.g. Grob *et al*. 1996, Bouso *et al*. 2015) this may well be our loss. But in pluralistic, secular societies, this cultural situation is unlikely to be changed by an argument that psychedelics facilitate access to non-natural realities. Some envision the possibility of psychedelics finding a broader-than-merely-medical role in contemporary society (e.g. Tupper 2003). For this to be possible, we need a metaphysically innocent, naturalistically palatable way of understanding what exactly these drugs offer besides the mimicry or alleviation of psychopathology.

Psychedelic Transformation: An Overview

Psychedelic drugs form a chemically and neuropharmacologically diverse group of substances. What unites them is phenomenology: despite differences in molecular structures and receptor binding profiles, all drugs classified as 'psychedelic' induce a characteristic type of altered state of consciousness. Psychedelic experiences are notoriously variable, being strongly influenced by 'set and setting' - that is, an individual's state of mind prior to ingestion, as well as the interpersonal and aesthetic environment (Sessa 2012). However, virtually every psychedelic experience involves alterations to some non-negligible subset of the following phenomenal modalities: sensory experience, affective experience, spatial and temporal experience, somatic experience, thinking or reasoning, and the sense of self (Strassman 2005). These alterations can be very mild or very intense, and can take the form of distortion, intensification, or diminution of exogenous mental contents, as well as the generation of endogenous mental contents with no apparent basis in the physical environment (Masters and Houston 1966).

This class of drugs has been referred to by a bewildering variety of names, including, but not limited to: hallucinogens, psychotomimetics, mysticomimetics, entheogens, schizogens, psychotogens, and, of course, psychedelics (Osmond 1957, Szara 1967, Ruck *et al*. 1979). This abundance of terminology reflects an abundance of uses. Naturally occurring psychedelics such as mescaline, dimethyltryptamine, and psilocybin have been used as religious sacraments in various cultures for centuries at least. Serious scientific interest in psychedelics was sparked by the accidental discovery in the 1940s of the extremely potent psychoactivity of lysergic acid diethylamide (LSD). In the 1950s and 60s, these drugs were studied and used in several different ways (Sessa 2012).

Psychologists and scholars of religion investigated the relationship between psychedelic intoxication and mystical experience, including, famously, experimental attempts to induce mystical states (Pahnke 1963). Various debates also occurred about whether psychedelic mysticism was equivalent to so-called 'genuine' mysticism or somehow inferior (Smith 1964). Meanwhile, psychiatrists used psychedelics in an attempt to understand mental illness - either by studying the psychedelic state as a 'model psychosis', or by experiencing it themselves in order to empathise with their patients. Somewhat surprisingly, psychiatrists also used psychedelics extensively as treatments. The 'psycholytic therapy' model involved classical psychoanalysis conducted under the influence of low doses of psychedelics, which were held to lower patients' defences and allow access to unconscious content. The 'psychedelic therapy' model, on the other hand, involved administration of high doses of psychedelics in order to induce an intense and overwhelming transformative experience (Sessa 2012).

Psychiatrists were very impressed by the efficacy of psychedelics, claiming extraordinary success rates with treatment-resistant alcoholism, as well as other conditions. However, much psychedelic science from the mid-20th century was methodologically sub-optimal by today's standards, often relying heavily on anecdotal evidence or lacking adequate controls, blinding, or follow-up (Doblin 1991, Strassman 1995a, Grob *et al*. 1998). In any case, after a brief heyday, psychedelics were soon made untenable both as treatments and as objects of research. Widespread uncontrolled use of these drugs in the context of the 1960s counterculture led to a moral panic which culminated in the banning of the substances and the subsequent cessation of human research for several decades (Sessa 2012).

Scientific study of the effects of psychedelic drugs on human subjects resumed in the late 1980s and early 1990s - most notably, with Rick Strassman's pioneering studies of dimethyltryptamine, or DMT (Strassman 1995b). These studies were investigations in basic psychopharmacology and did not involve any formal attempt to test for potential therapeutic or transformative effects (although the researchers were certainly aware of the possibility that such effects might occur; Strassman 2001.) Since then, however, many more studies have been conducted which suggest that the mid-20th century enthusiasm about psychedelics may not have been entirely unfounded. More research is still needed, but there is enough information to justify taking seriously the possibility of durable psychological change resulting from a single administration of a drug.

Psilocybin, the active ingredient[3] in 'magic mushrooms', has been perhaps the most widely studied psychedelic since the resumption of human research. One study involved the administration of psilocybin to 9 patients with obsessive-compulsive disorder, all of whom showed significant reductions in symptoms not only during the drug experience but also at a follow-up 24 hours later (Moreno *et al*. 2006). Another study tested the effects of a psilocybin session on late-stage terminal cancer patients experiencing anxiety related to their illness, and these patients displayed significant reductions in anxiety during the experience as well as at two month follow-ups (Grob *et al*. 2011). A similar study has also been conducted with terminal cancer patients using LSD instead of psilocybin, and similar results were found (Gasser *et al*. 2014). Recent studies have found promising results treating tobacco and alcohol addiction with psilocybin (Garcia-Romeu *et al*. 2014, Bogenschutz *et al*. 2015). Meanwhile, the psychedelic dissociative anaesthetic ketamine has been shown to cause a rapid reduction in symptoms of treatment-resistant major depression, with this reduction lasting up to a fortnight. Ketamine used in conjunction with existentially-oriented psychotherapy has also been shown to lead to higher rates of abstinence in heroin addicts (Vollenweider and Kometer 2010).

Apart from these studies of therapeutic effects, perhaps the most famous study conducted to date in the 'psychedelic renaissance' involved the administration of psilocybin to mentally healthy subjects who had no prior experience with psychedelics and who reported regular participation in religious or spiritual activities. Of the 36 subjects in this study, 22 experienced a 'complete' mystical experience as determined by the Hood Mysticism Scale and the States of Consciousness Questionnaire. A mystical experience in this sense has seven essential phenomenological components: internal and external unity, transcendence of time and space, alleged ineffability and paradoxicality, sense of sacredness, noetic quality, and positive mood (Griffiths *et al*. 2006). What is even more interesting is that those subjects who had a complete mystical experience showed significant increases in the core personality domain of Openness. The extent of these increases was predicted by the extent to which a given subject's mystical experience was 'complete', and the increases were diminished but still significant at 14-month follow-ups (MacLean *et al*. 2011). This is impressive because there are very few interventions which have been shown to cause durable and significant changes in any of the 'Big Five' personality domains in adult subjects.

Thus, there is good reason to think that a single administration of a psychedelic can, in conducive circumstances, lead to durable psychological benefit. I turn now to the nature of the transformative process whereby this occurs.

Evidence for the Causal Relevance of the ASC

As I mentioned earlier, bioethicists discussing psychopharmacological enhancement have expressed a concern that changing human personality by using drugs - especially for non-therapeutic or 'cosmetic' reasons - is inevitably dehumanising. One ground for this concern is expressed in the 2003 report of the President's Council on Bioethics as follows: '...biotechnical interventions act directly on the human body and mind to bring about their effects on a passive subject, who plays little or no role at all. He can at best *feel* their effects without *understanding their meaning in human terms*. Thus, a drug that brightened our mood would alter us without our understanding how and why it did so...' (President's Council on Bioethics 2003, 290; my italics).

Now, even if we disagree with the implicit normative verdict, we can recognise standard drug therapies such as antidepressants in this description. But psychedelic transformation seems different. My project begins by considering the intuition that the process of psychedelic transformation might be distinctive in some important or interesting way. This intuition is fuelled by the fact that most psychedelic subjects would *not* recognise psychedelic transformation in the above description. The phenomenology of psychedelic transformation is the antithesis of this kind of description - subjects feel themselves to be actively engaged in a process of transformation, one which crucially involves meaningful experiences and understanding (Masters and Houston 1966, Shanon 2002).

Of course, this feeling might be misleading. From the fact that it seems to subjects that they are engaged in a meaningful transformative process, it does not follow that they in fact are; they could be mistaken. The existence of this feeling does not preclude the possibility that the therapeutic benefits result from a direct pharmacological effect of the drug, unrelated to the ASC. If that were the case, the ASC - and associated feelings of meaningful transformation - would be a mere side-effect, therapeutically speaking. But note at this point that psychedelics certainly are distinctive psychopharmacological interventions in a couple of respects: they induce a vivid ASC which impresses subjects as meaningful, and they (sometimes) cause lasting benefits with a single dose. Standard drug therapies do neither of these things. This lends some initial plausibility to the idea that the subjects' impressions are accurate - that the durable changes to their cognitive and affective functioning are in fact brought about by a process which involves meanings and involves them as subjects. The idea that intense and meaningful experiences can have lasting effects on people is familiar and unmysterious enough, so we should consider the possibility that this is happening in psychedelic transformation.

Of course, to say that psychedelic transformation 'involves meanings' is imprecise and unsatisfactory. At this point I want to suggest an attractively clear and rigorous interpretation of this claim. I think it's quite natural to construe the claim as follows: the causal chain leading from (a) the ingestion of the psychedelic molecule to (b) the subject's enjoying a durable psychological benefit involves phenomenally conscious mental representations. Or, put differently, the psychological benefits are not caused solely by the drugs, but are caused at least partly by the altered state of consciousness, which itself is caused by the drugs.

Now, as I mentioned earlier, this is an empirical claim. We can render it yet more precise and tractable by understanding it as the hypothesis that the psychedelic experience is causally relevant to the psychological benefits. The philosopher Carl Craver, in his analysis of explanatory practice in neuroscience, develops an account of causal relevance as susceptibility to intervention and manipulation (Craver 2007). According to this analysis, the psychedelic experience is causally relevant to the long-term benefits if, and only if, we can reliably manipulate the latter by intervening to manipulate the former. I think there are at least four lines of evidence that this is the case, which I will discuss briefly in a moment.

Before I do discuss this evidence, though, I want to mention that the interpretation I've given of the claim of 'meaning involvement' is a fairly minimal one. I've construed this as the claim that the psychedelic ASC is causally relevant to the long term benefits. But of course that could be true without there being any interesting semantic relation between the acute drug experience and the durable benefits[4]. To see this, consider the possible world in which psychedelic drugs do nothing but induce in subjects vivid and colourful visions of Mickey Mouse. Suppose that in that world, as in the actual world, psychedelics show therapeutic potential for the treatment of conditions like OCD, addiction, and anxiety. And suppose, further, that the more vividly and realistically a given subject's visions portray Mickey Mouse, the greater the magnitude of the transformation enjoyed by that subject.

In the possible world I've just described, the psychedelic ASC is causally relevant to the long-term benefits. That is, we can manipulate the long-term benefits by intervening on the ASC. For instance, if there is a way to promote vividness and clarity of Mickey Mouse visions in certain subjects, then those subjects will enjoy greater benefits than other subjects who received identical doses but had less clear and vivid Mickey Mouse visions. So the minimal interpretation of the meaning-involvement claim is true in the possible world I've described. Nonetheless, it's pretty clear that the members of the President's Council on Bioethics would be unimpressed. This is because although meaning - by which I mean mental representation - is causally involved, that bare fact does not suffice to make the intervention one whose meaning can be "understood in human terms". What is needed for that is some more substantial semantic relation between the experience and the resultant benefits. A pretty clear example of the kind of relation at issue would be a case in which a person is forced under extreme circumstances to parachute out of a plane and consequently loses their lifelong fear of heights. This person has not only had their personality transformed by a conscious experience, but they can understand why that particular conscious experience should have had that particular effect on their personality.

That is the stronger sense of meaning-involvement: not just conscious mental representations being causally relevant to long-term benefits, but also bearing a semantic relation to those benefits such that the latter are rendered humanly comprehensible and able to be situated in a life narrative. Now, there is evidence that at least some cases of psychedelic therapy or transformation are meaning-involving in this stronger sense. Subjects do report having transformative experiences the content of which is transparently relevant to issues in their lives (Masters and Houston 1966; Shanon 2002). Suffice it to note, however, that the minimal interpretation of the meaning-involvement claim is necessary, if not sufficient, for the stronger one. So I shall here limit myself to arguing for the minimal claim that the ASC is causally relevant to the benefits. I turn now to the four lines of evidence for causal relevance.

The first is the phenomenology of psychedelic transformation mentioned earlier. Again, this is far from conclusive. But psychedelic subjects' belief that the benefits are caused by the intoxication merits attention. One possible naturalistic explanation of this belief is that it is true. Maybe subjects believe the intoxication transformed them because it did[5]. This point would be strengthened by some rigorous research into the relations between ASC contents and long-term benefits. Perhaps there are robust and identifiable correlations between certain specific experiential contents and certain specific benefits. Be that as it may, my claim here is just that the tendency of psychedelic subjects to report being transformed by a meaningful experience is a suggestive datum not to be ignored.

The second line of evidence concerns the existence of psychologically beneficial altered states of consciousness not induced by drugs. For example, there is evidence that psychological benefits can result from meditation practice (for reviews, see Davis and Hayes 2011, Goyal *et al*. 2014). Also, relationships have been found between non-drug-induced mystical experiences and measures of subjective well-being (Byrd *et al*. 2000) and durable, (largely) positive life changes are often reported following non-drug-induced near death experiences (Greyson 1997) - though there are obvious obstacles to studying such experiences in a controlled fashion. To the extent that these other altered states resemble psychedelic states, this suggests that the neuropharmacological action of the drugs is an inessential and in principle dispensable means to entering the altered state, which latter does the therapeutic work.

Of course, the question of similarities and differences between altered states is complex. But there is at least some evidence of commonalities between psychedelic and meditative states, as various psychedelic researchers have noted (Hoffmann *et al*. 2001, Palhano-Fontes *et al*. 2015, Stuckey *et al*. 2005). Deactivation of the posterior cingulate cortex has been observed to correlate with subjective experiences of selflessness (or ego dissolution) occasioned by both methods (Brewer *et al*. 2013). Various kinds of unusual experiences popularly associated with psychedelics are also frequently occasioned by meditation practice. Indeed, the sample data in Jack Kornfield's (1979, 45-50) phenomenological study of Buddhist insight meditation read like a compendium of psychedelic phenomena. Such observations as these form part of the motivation for empirical studies, currently in progress, testing the efficacy of psilocybin as an adjunct to meditation training (Brown and Reitman 2010).

One might object that this line of evidence relies on a spurious and unsustainable ontological distinction between the psychedelic ASC and the neuropharmacological action of the drug. Surely the ASC and the neuropharmacological action are in fact one and the same phenomenon, viewed at different levels of description. The evidence suggests this is not the case, however. Certainly the ASC is entirely constituted by abnormal patterns of neural and synaptic activity. Not all of this activity directly involves the psychedelic molecule, however. Psilocybin, for example, causes its psychological effects mainly by stimulating 5- HT2A receptors, which are found primarily on pyramidal neurons in cortical layer V (Carhart-Harris *et al*. 2014). The abnormal patterns of activity in these regions are at least partly constituted by the synaptic action of the drug itself. But abnormal activity in these regions leads in turn to abnormal patterns of activity in other (e.g. subcortical) regions to which these regions project, and those latter patterns are caused but not constituted by the drug action. We can express this by saying that the neuropharmacological action of the drug is a partially distinct sustaining cause of the ASC - only partially distinct because also partially constitutive, and sustaining because the ongoing drug action is necessary for the continuation of the psychedelic state. What I am suggesting, then, is that more variables than the direct drug action are involved in understanding the long-term effects. The downstream effects of that action in other brain regions are also important, and these effects are presumably a function not just of the direct drug action but of the prior state of the downstream systems (part of the 'set' in 'set and setting'.)

The third line of evidence that the ASC is causally relevant to the benefits relates to the fact that in some cases, variables quantifying the ASC have been found to predict variables quantifying the benefits. For instance, in the psilocybin mystical experience study mentioned earlier, the extent to which a subject's experience was mystical predicted the magnitude of increases in their personality domain of Openness (MacLean *et al*. 2011). This seems like clear evidence for causal relevance, in Craver's sense: evidence, that is, that if we could 'manipulate' psychedelic ASCs by creating conditions conducive to their being mystical, this would be a reliable means of manipulating the long-term benefits (in the direction of greater Openness increases.)

The question whether the psychedelic ASC is causally relevant to therapeutic benefits has been explicitly addressed by recent studies of ketamine. One small study of cocaine addicts involved three separate sessions: low dose ketamine, high dose ketamine, and lorazepam as an active placebo (Dakwar *et al*. 2014). These different infusions were given to subjects in a double-blind fashion on separate days. Psychological effects of each infusion were assessed using two different scales: one to measure dissociative type effects, and another to measure mystical type effects. It was found that higher mystical effect scores predicted increased motivation to quit cocaine, while higher dissociative effects did not. Further, variance in mystical effect scores predicted variance in increased motivation even across consistent dosages. That is to say that when you compare all the high-dose ketamine sessions, drug dosage is consistent between subjects. But there is variation in the kind of altered state subjects experienced, and this phenomenal variation predicts variation in therapeutic benefits 24 hours after the session. Once again, this is evidence that we can manipulate the lasting benefits by 'intervening on' the ASC, independently of drug dosage.

Such evidence for relationships between phenomenal variables and benefit variables is important. It would be considered a truism by those with firsthand experience of psychedelic research that the quality of the experience is relevant to the long-term outcome and can vary independently of dosage. Certainly it is possible for two people to consume an equivalent dose of a psychedelic but have vastly different experiences, one enjoying a mystic rapture and the other a nightmarish 'bad trip'. In such a case it would be very surprising if the long-term psychological consequences for the two people were the same[6]. But of course such clinical and anecdotal wisdom needs rigorous testing. It has been suggested that classic psychedelics and dissociative anaesthetics (such as ketamine) may share a common therapeutic mechanism in ultimately targeting glutamate-driven neuroplasticity (Vollenweider and Kometer 2010). One possibility is that this is sufficient for relatively long-term (i.e. weeks) psychological change but further, more specific experiential factors are required to capitalise on this neuroplastic window of opportunity and yield truly durable change[7]. The current instruments used in psychedelic research are relatively coarse-grained; they measure such variables as 'visionary restructuralization' but not specific experiential contents. Perhaps the development of more fine-grained psychometric instruments might reveal further interesting correlations between acute and long-term drug effects.

So, to recap: I construed the conjecture that psychedelic transformation is meaning-involving as entailing (at least) the empirical claim that the altered state is causally relevant to the benefits. Thus far, I've mentioned three kinds of evidence for that causal relevance claim: first, phenomenology; second, beneficial non-drug altered states; and third, correlations between phenomenal variables and psychological benefit variables. I turn now to the fourth line of evidence. This is based on recent neuroimaging studies of the psychedelic state, and also leads to questions about the potentially epistemic nature of psychedelic transformation.

Recently a team led by Dr. Robin Carhart-Harris of Imperial College London gave intravenous injections of psilocybin to healthy volunteers lying in fMRI machines (Carhart-Harris *et al*. 2012). When given intravenously, psilocybin has a very rapid onset and a short duration, which not only makes it practicable for neuroimaging but also allows very precise imaging of the transition from ordinary consciousness to psychedelic consciousness.

The findings from this study were fascinating in a number of respects. Notably, the transition to the psychedelic state involved only decreases, and no increases, in brain activity. This contradicts previous assumptions that psychedelics work by increasing brain activity, and so requires some explaining in its own right. Even more interesting, however, was the localization of these decreases. They were mainly found in the much-discussed Default Mode Network, so-called because it has the interesting property of being most active when a subject is at rest and not engaged in any particular task. When a cognitive or behavioural task is begun, activity in the DMN decreases and activity in other networks correspondingly increases (Raichle *et al*. 2001).

The DMN is also interesting because it displays significantly higher metabolic activity than the average brain region and is extremely densely connected to many other regions. This suggestive set of observations has led to a lot of debate about what exactly the DMN does. Its role is still a matter of controversy, but it has been implicated in various self-referential and metacognitive functions, including daydreaming and 'mental time travel' - that is, the simulation of past and future events (Spreng and Grady 2010). Some theorists have also linked the DMN to the 'narrative self' (D'Argembeau *et al*. 2014).

In discussing their findings, Carhart-Harris and colleagues note that not only did activity in various DMN regions diminish under psilocybin, but many of the normal patterns of connectivity both internal and external to the DMN were disrupted. The result, from the standpoint of global neural dynamics, was a system in a much more disordered and unpredictable state than is ordinarily the case. The authors speculate that this is because the DMN ordinarily acts as a supervisory system which imposes inhibition and constraint on other cognitive systems, and hence disruption to the DMN in the psychedelic state results in a condition of unconstrained cognition (Carhart-Harris *et al*. 2014).

Most relevant to my concerns here are the speculations Carhart-Harris and colleagues make about the mechanisms of psychedelic therapy. They note that various conditions for which psychedelics show therapeutic promise - including OCD, depression, and addiction - can illuminatingly be characterised as 'over-rigid' conditions. A depressed or obsessive system is one trapped for whatever reason in a narrow region of state space. In light of this, they propose that a psychedelic experience might be therapeutic because it forcibly shakes the system out of its rut, freeing it from its rigid confinement and leaving a greater dynamical flexibility which outlasts the experience itself. The point of this, of course, is that this is a conjectural model of psychedelic therapy on which the experience is certainly causally relevant to the benefits[8].

It is important to note that the psychedelic experience and subsequent benefits are here being described in purely dynamical terms. This raises interesting questions about different levels and kinds of explanation in the cognitive sciences. There are long-running debates about the explanatory credentials of dynamical models (e.g. van Gelder 1998, Kaplan and Bechtel 2011) and the case of psychedelic therapy readily reveals the limitations of such models alone. Carhart-Harris *et al*. place great importance on entropy as a quantifiable explanatory construct in understanding the mechanisms of psychedelic therapy. However, transiently elevated entropy is insufficient for therapeutic benefit. This is because two different psychedelic experiences could be equally entropic even though one is a blissful mystical-type experience which leads to durably increased openness and the other is a hellish bad trip which leads to trauma and subsequent nightmares. (Such results do occur, although they are very rare in carefully conducted controlled research.) It may be that de-rigidifying the cognitive system by elevating its entropy is necessary but not sufficient for therapeutic benefit, and it is also necessary that the experience have contents of a certain kind. Acute psychotic experiences presumably involve elevated entropy, though they are distinct from controlled psychedelic states in at least three important ways: they are not voluntary, they are not of a fixed and known duration, and they are not accompanied by insight. All this notwithstanding, the neuroimaging studies combined with the rigidity characteristic of depression and other conditions do provide some evidence that increasing cognitive flexibility is an element of the therapeutic process. Therefore, the studies constitute a fourth and final line of evidence that the psychedelic experience is causally relevant to the long-term benefits. So there is good reason to accept the descriptive claim that psychedelic transformation is a distinctively meaning-involving psychopharmacological intervention.

I emphasise that this is a descriptive claim because I am refraining from entering into the normative bioethical debates about the relative merits of meaning-involving and non-meaning-involving transformative processes. I think the meaning-involving nature of psychedelic transformation is surely a fact highly relevant to policy debates, but my project here is purely descriptive. For me, the next interesting set of issues concerns exactly what kinds of meanings are respected or involved in psychedelic transformation, and how.

Epistemic Aspects of Psychedelic Transformation

Psychedelic subjects very often feel that they gain knowledge through their experiences. However, they also reasonably often come to entertain non-naturalistic metaphysical beliefs as a consequence of their experiences (Vaughan 1983, Strassman 2001, Shanon 2002). It is an interesting question what to say about this from a naturalistic perspective. Is the sense of epistemic benefit experienced by these subjects simply illusory? Or is there some kind of naturalistically palatable epistemic benefit which subjects might indeed be gaining, notwithstanding such metaphysical conversions? I think there are perfectly naturalistic epistemic benefits which may well result from psychedelic states.

The first one follows very naturally from the 'unconstrained cognition' theory of the psychedelic state. If this theory is correct, then cognitive systems, while psychedelically intoxicated, traverse wider regions of state space than they do at other times. Often they enter into completely novel and unfamiliar regions of state space, and often these are very distant from the more familiar regions of ordinary waking consciousness. In light of this, I propose that psychedelic experience can be a means of gaining knowledge by acquaintance of one's own vast psychological potential.

Consider, for example, Aldous Huxley. Prior to his famous mescaline experience in 1952, Huxley was a serious student of the mystical literature of the world's religions. He had knowledge by description - by testimony, in fact - of the existence of certain regions of the human phenomenal state space. He believed, truly and justifiably, that there existed certain possible ways for his mind to be - arguably intrinsically and instrumentally valuable ways featuring such things as intensified perceptions and emotions, greatly enhanced appreciation of the world, and a sense of kinship with all of existence. But he may well have doubted, as do many aspiring mystics, that these ways of being were genuine possibilities *for him*. After the 3*rd* of May, this doubt was gone. Huxley had acquired a new kind of knowledge about the potential of his mind - he had become directly acquainted with its ability to enter states of absorption, harmony, and unparalleled wonder and awe (Huxley 1994). In this context, it is worth mentioning that many senior Western teachers of meditation were inspired by experiences with psychedelic drugs in the 1960s (Badiner and Grey, eds. 2002, Dass 2005). It is plausible to think that they were drawn to the discipline of meditation because they gained knowledge about the immense potential of their own minds. They were then driven to investigate the possibility of realising the potential about which they had gained knowledge.

So psychedelic experiences may well be a means to acquire knowledge by acquaintance of one's own psychological potential. This is, of course, perfectly naturalistic. A second naturalistically palatable kind of knowledge which such experiences might afford is slightly more controversial. This is knowledge by acquaintance[9] with the metaphysical nature of the self.

As I mentioned earlier, some theorists have speculated that the Default Mode Network is the neurocognitive substrate of the narrative self - the sense of one's persistent identity as a distinct individual with a history, which sense is constituted by narratively structured representations of one's past and future. Some theorists inclined towards the research programme known as 'neuropsychoanalysis' have even suggested that the DMN is the substrate of the Freudian ego (Carhart-Harris and Friston 2010). While remaining agnostic on the precise details, the fMRI studies of psilocybin mentioned earlier offer suggestive evidence about the neurocognitive substrate of the sense of self (Carhart-Harris *et al*. 2012). One of the key nodes of the DMN is the posterior cingulate cortex (PCC). In the studies in question, there was a strong correlation between decreases in PCC activity and ratings for one specific item on the psychological questionnaire used to quantify subjects' experiences. This item, scores for which tracked diminution in PCC activity, read as follows: "I experienced a dissolution of my self or ego" (Carhart-Harris *et al*. 2014).

Obviously a more careful treatment of this point is required. But I think the fact that the psilocybin-induced deactivation of the PCC leads subjects to report a dissolution of their ordinary sense of self suggests that, no matter how real and inviolable it feels in the normal course of things, the sense of self is in fact a model of some kind[10] generated by specific cognitive systems in the brain (cf. Metzinger 2003, 2009). On the basis of ordinary waking life, it is tempting to assume that an experiencing subject is a transcendental precondition for the possibility of experience - that the idea of experience without a self is incoherent. The idea here is that this assumption is false - it is a case of incorrectly inferring necessity from constant conjunction - and psilocybin subjects become directly acquainted with this fact. That is, they gain experiential knowledge of the contingency of their own sense of self by experiencing its temporary subtraction from their phenomenal space. Even if this does not show the sense of self to be a *mere* model, the possibility of experience without the feeling of a subject - the possibility of "thoughts without a thinker” (Epstein 2004)—is a striking discovery to make.

It should be clear that there is no contradiction in the idea that psychedelic therapy is a person-involving process which happens to involve a dissolution of the sense of self. It is quite consistent and plausible to think that the sense of self is a mere part of persons considered as experiencing entities - this sense is just one type of experience which such entities typically, but not invariably, have. It is the person, in the sense of the conscious cognizing organism, which has, and unproblematically later remembers, the experience of ego dissolution.

The two suggestions I've made so far concern the possibility of direct epistemic benefit, of gaining knowledge during the psychedelic experience itself. I will finish by proposing one way in which a transformative or therapeutic psychedelic experience might lead to indirect epistemic benefit. This is by restoring the capacity to acquire modal knowledge[11] by restoring the subject's imaginative flexibility.

People suffering from depression, for instance, have difficulty imagining other ways that they could be or certain courses of action they could take. Part of the rigidity mentioned earlier is imaginative rigidity. Once again, the system is trapped in a narrow region of state space and tends not to envision creative solutions to problems or novel behavioural strategies. This seems straightforwardly to be a state of impoverished modal knowledge. There are possibilities available, but the suffering subject is unable to imagine these possibilities and thus unable to know of their availability. In this light, consider the conjectural dynamical model of psychedelic therapy: the system is temporarily unconstrained, conferring a degree of freedom and flexibility, some measure of which outlasts the acute experience. One way this greater flexibility could manifest is as an increased ability to imagine possibilities. And a greater ability to imagine possibilities is, at least, a higher level of access to putative modal truths about oneself and one's life.

Conclusion

To summarise: psychedelic drugs form a phenomenally defined class which includes serotonin agonists such as LSD, DMT, psilocybin and mescaline, as well as dissociative anaesthetics such as ketamine, and other drugs besides. Psychedelic drugs induce a distinctive and intense kind of altered state of consciousness which is different from the altered states induced by drugs of other classes. Psychedelics have been studied again in the last two decades as therapeutic and transformative agents, yielding evidence that they can cause lasting psychological benefits with a single dose or with very few doses.

Some bioethicists worry that cosmetic psychopharmacology is dehumanising because drugs transform passive subjects in a way that is subjectively opaque and not comprehensible in meaningful human terms. A passing acquaintance with the literature on psychedelic therapy leads to the intuition that psychedelic transformation is unlike this. In particular, it seems to be more transparent and meaning-involving. I precisified this intuition as the claim that the psychedelic ASC is causally relevant to the long term benefits, and reviewed four lines of evidence for this claim. These were: first, the phenomenology of psychedelic transformation; second, the existence of beneficial non-drug altered states; third, correlations between phenomenal variables and benefit variables in a dose-independent fashion; and fourth, the de-rigidifying model of psychedelic therapy based on neuroimaging results.

In closing, I suggested three naturalistically palatable kinds of epistemic benefit which might derive from psychedelic experiences: two direct, and one indirect. The first direct kind of benefit is acquiring knowledge by acquaintance of one's own psychological potential. The second direct kind of benefit is acquiring knowledge by acquaintance of the contingency of one's sense of self. And the indirect kind of benefit is a rejuvenation of cognitive capacities which are important for the acquisition of modal knowledge. Many questions remain, but the old idea of drug-induced epistemic benefit merits serious attention, even given naturalism[12].

The Epistemic Innocence of Psychedelic States

Statement of Authorship

Title of paper:	The Epistemic Innocence of Psychedelic States
Publication status:	Published
Publication details:	Letheby, C. (2016). The epistemic innocence of psychedelic states. Consciousness and Cognition 39, 28-37.
Principal Author	
Name of principal author (candidate):	Christopher Letheby
Contribution to the paper:	Devised the arguments and wrote, proofread, polished, formatted, and submitted the paper.
Overall percentage (%):	100%
Certification:	This paper reports on original research I conducted during the period of my Higher Degree by Research candidature and is not subject to any obligations or contractual agreements with a third party that would constrain its inclusion in this thesis. I am the primary author of this paper.

Introduction

The recent renaissance of scientific research into psychedelic drugs has provided evidence that these controversial substances can confer lasting psychological benefits in just one or two sessions. Small studies have found promising results using LSD and psilocybin to treat addiction (Johnson *et al*. 2014, Bogenschutz *et al*. 2015), obsessive-compulsive disorder (Moreno *et al*. 2006), and anxiety relating to terminal illness (Grob *et al*. 2011, Gasser *et al*. 2014). This method is unlike existing psychiatric treatments in that it relies crucially on the temporary induction of a dramatically altered state of consciousness (Letheby 2015), at least in some cases (Majiæ *et al*. 2015). While in this altered state, patients often have extremely convincing experiences of what seems to be a mystical, immaterial ultimate reality underlying the universe, and there is some reason to think that these mystical experiences can be important for the therapeutic effects (Bogenschutz and Johnson 2015, Majiæ *et al*. 2015). Indeed, one eminent scholar of religion has said that "the basic message of [these drugs is] that there is another Reality that puts this one in the shade" (Smith 2000). This raises difficult questions. Michael Pollan, writing in the New Yorker recently, put it well:

> It's one thing to conclude that love is all that matters, but quite another to come away from a therapy convinced that "there is another reality" awaiting us after death ... or that there is more to the universe - and to consciousness - than a purely materialist world view would have us believe. Is psychedelic therapy simply foisting a comforting delusion on the sick and dying?
> (Pollan 2015).

In this paper I argue that even if psychedelic therapy is "foisting a comforting delusion on the sick and dying" it is not *merely* doing so. To make this argument, I rely on conceptual resources developed in epistemology, the philosophical study of knowledge. The philosopher Lisa Bortolotti and colleagues (Bortolotti 2015a, 2015b, Bortolotti and Miyazono 2016, Sullivan-Bissett 2015) have recently introduced the concept of 'epistemic[13] innocence' to articulate the idea that certain epistemically sub-optimal states such as delusion and confabulation may have not just psychological but epistemic benefits. They urge us to resist a simplistic trade-off view according to which psychological benefits are purchased with epistemic costs. I apply their analysis to psychedelic therapy and argue that at least some psychedelic states are epistemically innocent imperfect cognitions.

I proceed as follows. In section 1, I give a brief overview of psychedelic therapy: the history and phenomenology of these drugs and recent evidence for their therapeutic and transformative efficacy. In section 2, I describe the concept of epistemic innocence and its application by Bortolotti to delusion. In section

3, I argue that psychedelic states can have significant epistemic benefits. This discussion touches on some interesting issues arising from the fact that psychedelic states, unlike many other imperfect cognitive conditions, are voluntarily entered. In section 4, I argue that often no alternative cognitions are available which will deliver the same epistemic benefits as psychedelics. In the course of making this argument, I highlight a potential ambiguity in the formal definition of epistemic innocence. Finally, in section 5, I reflect on the implications of my discussion. The epistemic innocence of psychedelic states has broad consequences. Mounting evidence for the benefits of psychedelics is leading to a re-evaluation of the potential of these substances as tools in psychiatry and beyond (e.g. Sessa 2005, 2008, Sessa and Johnson 2015). I argue that such policy discussions ought to be based on a comprehensive understanding of the merits and demerits, epistemic included, of the drugs.

Psychedelic Therapy: An Overview

There has recently been a renaissance of scientific research into the effects of psychedelic drugs on human subjects in controlled conditions. Although more evidence is required, including replications with larger sample sizes, the results to date give us good reason to take seriously the idea that these drugs can durably change personality and alleviate psychiatric distress with just one or two administrations. In this section, I give a brief history of psychedelics, followed by a review of the recent evidence for therapeutic and transformative efficacy, in order to set the scene for my discussion of epistemological issues.

Sporadic earlier research notwithstanding, the story of modern psychedelic science really begins in 1943, when the Swiss chemist Albert Hofmann accidentally ingested a minute quantity of lysergic acid diethylamide or LSD-25, a chemical he had been developing for medicinal purposes. He famously described the result as follows:

> At home I lay down and sank into a not unpleasant intoxicated-like condition, characterised by an extremely stimulated imagination. In a dreamlike state, with eyes closed … I perceived an uninterrupted stream of fantastic pictures, extraordinary shapes with intense, kaleidoscopic play of colours.
> (Hofmann 1980).

Shortly afterwards, it was recognised that LSD's effects were similar to those of the naturally occurring substances mescaline, found in the peyote cactus, and psilocybin, found in 'magic' mushrooms. British psychiatrist Humphry Osmond (1957) coined the term 'psychedelic', meaning 'mind-manifesting', to describe this newly recognised class of drugs with its distinctive profile of effects. The three drugs I have mentioned not only produce similar effects but act by a common mechanism: stimulation of serotonin 2A receptors (Halberstadt 2015). Various other drugs which produce similar effects by different mechanisms of action have also been classified as 'psychedelic' (Sessa 2012). However, here I restrict myself to discussing the so-called 'classic' serotonin 2A agonist psychedelics (apart from a brief mention of the NMDA antagonist dissociative anaesthetic ketamine, also currently being studied for its therapeutic potential.)

Describing the effects of psychedelics in general is difficult for at least two reasons: first, because they are often held to defy description, and second, because they are extremely variable, being highly dependent on 'set and setting' - that is, the subject's prior state of mind and the external environment. One definition holds that a psychedelic is a drug

> which, without causing physical addiction, craving, major physiological disturbances, delirium, disorientation, or amnesia, more or less reliably produces thought, mood, and perceptual changes otherwise rarely experienced except in dreams, contemplative and religious exaltation, flashes of vivid involuntary memory, and acute psychosis.
> (Grinspoon and Bakalar 1979).

Such "thought, mood, and perceptual changes" might include seeing static objects as moving or warping, vast and colourful visions of ancient civilizations with the eyes closed, emotional extremes of euphoria or terror, or a sense that one's ordinary everyday identity has dissolved into a timeless ultimate reality - to name just a few (Masters and Houston 1966). Very often there is a sense of insightfulness, understanding, or new perspectives, either with respect to personal life issues or with respect to broader - often philosophical - themes (*ibid.*, Shanon 2002).

Psychedelics have been used for religious and medicinal purposes by traditional cultures for centuries, if not millennia (Masters and Houston 1966). After coming to the attention of Western science in the 1940s, they were studied from several different perspectives. The 'psychotomimetic' paradigm emphasised the similarity between psychedelic states and naturally occurring psychotic states. Researchers in this paradigm studied psychedelics to try to gain clues about the biochemical basis of mental illness, while psychiatrists sampled psychedelics in order better to empathise with their psychotic patients (Osmond 1957).

Remarkably, as well as being used to model mental illness, psychedelics were used to treat it. Psychotherapy with psychedelics tended to follow one of two models: 'psycholytic therapy' involved classical psychoanalysis conducted under the influence of low doses of psychedelics, on the grounds that the drugs lowered psychological defensiveness and provided access to unconscious material; 'psychedelic therapy', meanwhile, involved the administration of high doses of psychedelics in order to induce an overwhelming, transformative 'peak' or 'mystical' experience (Grinspoon and Bakalar 1986). Clinicians were very impressed with the therapeutic efficacy of psychedelics, but most of this early research was methodologically problematic by today's standards. Studies often lacked control groups, blinding, and follow-ups, and relied heavily on anecdotal evidence (Sessa 2005). However, one recent meta-analysis of early research did find evidence for the efficacy of high-dose LSD in the treatment of alcoholism (Krebs and Johansen 2012).

Ultimately scientific research and clinical practice with psychedelics was curtailed after the drugs became politically controversial in the 1960s. Widespread uncontrolled use by members of the hippy counterculture led to a highly emotive public debate which culminated in the prohibition of psychedelics. After this, virtually no human research was conducted for some decades (Sessa 2005).

Since the early 1990s, in a changed political climate, human research with psychedelics has slowly but steadily resumed, with intriguing results. Importantly, it has been demonstrated repeatedly and rigorously that it is possible safely to give moderate or high doses of psychedelics to carefully screened and prepared subjects in controlled clinical settings without serious adverse effects (Johnson *et al*. 2008). Various studies have also examined the drugs' therapeutic and transformative potential.

In one study, 9 patients with obsessive-compulsive disorder, all of whom had failed to respond to standard treatments, showed significant reductions in symptoms during the drug experience and at a follow-up 24 hours later (Moreno *et al*. 2006). Another study tested the effects of a psilocybin session on terminal cancer patients experiencing anxiety, and these patients showed significant reductions in anxiety and depression during the experience and at follow-ups two and six months later (Grob *et al*. 2011). A similar study using LSD instead of psilocybin found similar results (Gasser *et al*. 2014). Recent pilot studies have found promising results treating tobacco and alcohol addiction with psilocybin (Johnson *et al*. 2014, Bogenschutz *et al*. 2015). Promising results have also been found using ayahuasca, a South American shamanic beverage containing the classic psychedelic DMT, to treat addiction (Thomas *et al*. 2013) and depression (Osório *et al*. 2015).

Another study examined the effects of psilocybin on mentally healthy religiously-inclined volunteers. 22 of 36 subjects had a 'complete' mystical experience as measured by psychometric scales, involving feelings of unity, transcendence of time and space, and extreme positive affect (Griffiths *et al*. 2006). Those who had a mystical experience showed increases in the personality dimension of openness which were diminished but still significant 14 months later. Importantly, the intensity of their mystical experience predicted the extent of their increases in openness (MacLean *et al*. 2011).

This brief review of recent research reveals substantial evidence that psychedelic drugs can cause lasting psychological benefits with just one or two doses. The mechanism whereby they achieve this result remains uncertain but there is reason to think that the altered state of consciousness induced by the drugs is crucially involved. Specifically, mystical states of consciousness seem to have the greatest therapeutic benefit. In the psilocybin study just mentioned, the extent of mystical experience predicted the degree of personality change. And in the study of psilocybin for tobacco addiction, mystical experiences predicted therapeutic outcome (Garcia-Romeu *et al*. 2014). In the alcoholism study, mystical experience - as well as overall intensity of drug effects - predicted improvements to drinking behaviour (Bogenschutz *et al*. 2015).

From the perspective of philosophical naturalism - the view that the natural world is all that exists - such mystical experiences must be considered illusory, which leads to a troubling picture indeed. A treatment modality which has been hailed as the "next major breakthrough in mental health care" (Jacobson 2014) seems to work, at least in part, by inducing highly compelling metaphysical illusions. For help in thinking about this situation, I turn now to the recent philosophical work on epistemic innocence.

The Concept of Epistemic Innocence

The common saying 'ignorance is bliss' encapsulates the familiar idea that epistemically suboptimal cognitions can cause psychological benefits. Consider the case of motivated delusions. Delusions, in general, are very difficult to define without controversy, but one relatively neutral description holds that they are "strange beliefs[14] which appear in the context of mental distress" (Bortolotti 2013). Delusions may be elaborate, complex narratives accounting for much of a person's experience, as in schizophrenia, or they may be more circumscribed. A certain subclass of circumscribed delusions has been described as 'motivated delusions' on the grounds that these delusions may serve a defensive function, protecting people from the negative psychological consequences of facing unpleasant or devastating truths. Examples of motivated delusions include Reverse Othello syndrome, the delusion that one's romantic partner is faithful; erotomania, the delusion that a stranger - often a famous person - is in love with one; and anosognosia, the denial of illness (Bortolotti 2015a).

Lisa Bortolotti (*ibid.*) notes that solely motivational explanations of the formation of many of these delusions are implausible. However, irrespective of what role, if any, motivation plays in their formation, it is plausible that such delusions can be psychologically beneficial in the kinds of circumstances in which they are typically held. Bortolotti discusses a few cases, including that of 'BX', a musician whose partner left him after he was rendered quadriplegic by a car accident. BX later developed Reverse Othello syndrome, becoming convinced that not only were he and his former partner still together, but that they had married. It is not difficult to see how this delusion could have psychologically benefited BX by saving him from confronting the totality of the awful truth of his situation. He was both quadriplegic *and* single; his life as he knew it had fallen apart. Accepting this could have been utterly debilitating.

Bortolotti discusses other cases for which similar points can be made. One is that of 'LT', a reserved, socially isolated and lonely person, who had recently been through an abrupt relationship break-up and had subsequently developed erotomania. Her erotomania took the form of a delusion that a former fellow student, to whom she had never spoken, was in love with her. It is easy to see how this delusion could have provided psychological consolation given her situation. And the same point can be made for anosognosia - the denial of illness - which often emerges in the context of a traumatic or sudden injury.

When we think about such cognitive conditions as these delusions, it is natural to assume a fairly straightforward 'trade-off' picture according to which, whatever psycho-emotional benefits they may have, their only epistemic effects are detrimental. They may increase a person's happiness or well-being, but they only ever decrease a person's knowledge. Bortolotti argues that often the picture is more complicated. She notes that in addition to the kinds of psychological benefits described above, delusions very often have detrimental psychological effects, putting strain and stress both on the agent's internal cognitive processes and on their relationships with others. The epistemic picture, she says, can be similarly mixed: despite their obvious epistemic costs, such cognitive conditions can deliver significant epistemic benefits which are otherwise unavailable to the agent at that time.

Bortolotti introduces the concept of 'epistemic innocence' to articulate this idea. She proposes two conditions which an imperfect, or epistemically sub-optimal, cognitive process must meet to nonetheless qualify as epistemically innocent. The first of these is the 'Epistemic Benefit' condition: "The [sub-optimal cognitive process] confers a significant epistemic benefit to the agent at the time of its adoption"; and the second is the 'No Alternatives' condition: "Other [cognitive processes] that would confer the same benefit are not available to that agent at that time" (Bortolotti 2015a, 496). Having defined the concept thus, she argues that motivated delusions sometimes satisfy these two conditions.

The concept of epistemic innocence is based on the legal notion of an 'innocence defence', in which an act which would ordinarily be a criminal offence can be excused on the grounds that it was necessary to prevent catastrophe. As we will see shortly, Bortolotti thinks the epistemic status of motivated delusions is sometimes analogous to this: they prevent epistemic catastrophe by committing what would ordinarily be an epistemic crime. The epistemic offence is excused by virtue of its constituting an "acceptable response to an emergency" (Bortolotti 2015a, 495). It is worth noting that this is a richer notion than is captured by the minimal, formal definition of epistemic innocence cited above, which includes no explicit reference to the prevention of catastrophic outcomes. I think this is a strength, not a weakness, of the formal definition. The cases of psychedelic therapy which I will discuss below do not all fit the catastrophe-prevention or emergency-response model. But they do fit the more minimal conception of an epistemic cost being somewhat offset by a significant and otherwise unavailable epistemic benefit. This minimal conception has the advantage of illuminating such cases, not just those which more closely fit the original analogy. Like the cases of implicit bias-driven confabulation discussed by Sullivan-Bissett (2015), psychedelic therapy highlights the broader significance of the concept of epistemic innocence as formally defined. It is not merely a defence of epistemically costly emergency responses, but an invitation to "a more balanced view of the role of [imperfect cognitions] ... [and] a reflection on the role of contextual factors in epistemic evaluation" (Bortolotti 2015a, 490).

Let us return to Bortolotti's arguments for the epistemic innocence of motivated delusions. With respect to the Epistemic Benefit condition, the basic idea is that when these delusions cause psychological benefits, those in turn cause epistemic benefits. Insofar as the Reverse Othello syndrome developed by BX protected him from total psychological collapse, it enabled him to keep communicating and engaging with doctors, nurses and visitors. And communicating with others is one of the main methods - for BX, one of very few available methods - whereby we gain information about the world. BX's delusion may have compromised his access to knowledge about the condition of his romantic relationship, but it facilitated his access to knowledge about the course of his treatment, the weather outside, local politics, and any other topic about which he may have communicated with other people. This basic idea can be applied similarly to LT's erotomania and to cases of anosognosia. Insofar as delusions benefit a person psychologically by keeping them from despair, they thereby benefit a person epistemically by allowing them to keep engaging with other people and their environments, thereby acquiring knowledge (Bortolotti 2015a).

The No Alternatives condition is slightly less clear, since it is a substantive issue in itself what counts as the 'availability' of a cognitive process to an agent at a time. In discussing this, Bortolotti reviews empirical evidence suggesting that the belief revision capacities of patients with anosognosia are often compromised, limiting their ability to replace their delusion with the true belief that they are ill. She makes a more general point, however, which applies to all the motivated delusions discussed thus far. If it is true that these delusions provide psychological benefit by protecting against a potentially catastrophic or debilitating true belief, then it is unlikely that the relevant true beliefs would provide the same epistemic benefits conferred by the delusions. In the case of BX, for instance, a true belief about his relationship would provide one obvious epistemic benefit not provided by the delusion - that of knowing the truth about his relationship. But if this true belief were devastating, it would fail to yield all the epistemic benefits which arise from engagement with people and the environment. So it seems there is no alternative to the delusion available to BX *which would provide the same epistemic benefits gained from the delusion but without its epistemic costs*.

Epistemic Benefit and Epistemic Risk

If naturalism is true, and if mystical experience is the primary mechanism of psychedelic therapy, then it seems undeniable that psychedelic therapy is "foisting a comforting delusion on the sick and dying". However, equipped with the concept of epistemic innocence, we are now in a position to appreciate the respects in which it is not *merely* doing so. The epistemic appraisal of psychedelic therapy - like that of motivated delusion - is more complicated than it might at first appear.

When therapeutic psychedelic experiences alleviate debilitating psychiatric conditions such as alcoholism, they satisfy the Epistemic Benefit condition in the same way as motivated delusions. The recovered alcoholic is far more likely to engage with other people and the broader environment, and thus likely to acquire much more knowledge. Given the reversibility of some alcohol-induced cognitive impairment, the psychedelically recovered alcoholic is also likely to benefit from improved functioning of epistemically important cognitive capacities such as attention and working memory (Mann *et al*. 1999).

The same process of epistemic benefit will occur when psychedelic therapy is applied to other debilitating conditions such as anxiety associated with terminal illness. As a result of psychedelic therapy, patients with terminal illness experience significant and lasting reductions in anxiety and depression (Grob *et al*. 2011, Gasser *et al*. 2014). Lower levels of anxiety and depression will tend to lead to more engagement with the environment and therefore more knowledge acquisition. Successful psychedelic therapy has epistemic benefits.

There is another point worth making about therapeutic psychedelic trips, albeit one not directly relevant to their satisfaction of the Epistemic Benefit condition. It has often been noted that psychedelic subjects, unlike psychotic patients, typically retain insight; that is, they are aware that their unusual experiences have been occasioned by the ingestion of a drug (Hermle *et al*. 1992). This retention of insight does not uniformly beget epistemic conservatism: many psychedelic subjects are convinced that they have enjoyed drug-induced *but nonetheless veridical* metaphysical apprehensions. However, the important point is that non-naturalistic metaphysical conversions are not guaranteed to result even from spectacularly mystical psychedelic trips.

An instructive case is Benny Shanon (2002) the Israeli cognitive scientist, philosopher, and veteran of over 130 experiences with the South American psychedelic brew ayahuasca. It is fair to say that Shanon has experienced and been suitably impressed by a representative sample of psychedelic experience. But in his monograph on ayahuasca he treads a commendably cautious line, rejecting various paranormal claims associated with psychedelics, while flirting with a pragmatic or poetic approach to the idealistic pantheistic metaphysical vision often encountered on this drug. Shanon is living proof that it is possible to experience the full power of psychedelic mysticism in an epistemically responsible way - though of course he is unusually well equipped to do so by virtue of his professional training. It can bring further balance to our epistemic evaluation of psychedelic therapy to note that, while it may be an epistemically risky treatment modality from a naturalistic standpoint, the risk is not absolute.

This mention of epistemic risk highlights an interesting feature of the case of psychedelic therapy. The kinds of imperfect cognitions which have thus far received attention in the epistemic innocence literature - motivated delusions (Bortolotti 2015a), elaborated and systematized delusions (Bortolotti 2015b), implicit bias and confabulation (Sullivan-Bissett 2015) - are all involuntary. As such, the concept of epistemic innocence is applicable to the objective assessment of the epistemic status of these cognitions, as well as to practical questions about how others (e.g. clinicians) ought to interact with the subjects of such cognitions. The present case differs in that introducing the notion of epistemic innocence could perhaps help individuals deciding whether or not to *voluntarily* enter an epistemically detrimental or risky cognitive state.

Imagine a naturalistic, atheistic terminal patient who has been offered a place in a psychedelic therapy trial. A second- or third-hand acquaintance with the phenomenology of psychedelics might lead this patient, reasonably enough, to share Pollan's worry that they would be signing up to acquire a "comforting delusion". To appreciate the point, consider Pascal's Wager, which says we ought to try to bring about theistic belief in ourselves, because belief has higher expected utility than disbelief. That is, belief has vast advantages if God exists but only moderate disadvantages if God does not exist, while disbelief has vast disadvantages if God exists but only moderate advantages if God does not exist. Now, one possible response, in line with the 'evidentialist' tradition derived from the work of W. K. Clifford (1877), is that beliefs ought never be adopted for pragmatic reasons, but only ever on the basis of sufficient evidence. One need not hold such a strong view, however, to share the basic worry: that there is something ethically suspect (because intellectually dishonest) about adopting a belief solely for pragmatic reasons. The prospective psychedelic therapy subject might reasonably wonder if they are contemplating something a little too akin to following Pascal's advice.

Appreciating the epistemic innocence of psychedelic states could help such an epistemically responsible person to appreciate the disanalogies between psychedelic therapy and Pascal's prescription. The potential epistemic costs of psychedelics are offset not just by pragmatic benefits, but by significant and (I will later argue) otherwise unavailable epistemic benefits. It is not a simple purchase of pragmatic benefits with epistemic costs, and this makes a difference to the decision under consideration. It makes a further difference to note that, as illustrated by the case of Shanon, epistemic costs are not an inevitable result of psychedelic transformation but merely a risk.

How large a risk? It is hard to say. It would be interesting to know the statistical relationships between therapeutic and transformative effects and the acquisition of new non-naturalistic metaphysical beliefs consequent on psychedelic ingestion, but such research has not been conducted to my knowledge. Prolonged psychosis is one epistemic (and, of course, psychological) risk of psychedelics. This risk is very low when the drugs are given in carefully controlled conditions, but is known to be higher when they are consumed in uncontrolled conditions (Strassman 1984, Johnson *et al*. 2008). Perhaps the risk of forming extravagant or unwarranted metaphysical beliefs is also higher when the drugs are consumed - especially repeatedly - in uncontrolled conditions. This possibility is suggested by some of the more colourful theories espoused by, for instance, the late Terrence McKenna (1991), countercultural icon and prolific high-dose psychedelic user. If (repeated) uncontrolled psychedelic use does carry elevated epistemic risk, then this might be another reason - in conjunction with the elevated pragmatic risk - militating against such use. At any rate, in the case of just one or very few clinically supervised psychedelic therapy sessions, significant epistemic and pragmatic benefits are highly likely, and epistemic costs not overwhelmingly likely, making the epistemic risk perhaps a reasonable one to take. Of course, the precise risk/benefit analysis will vary depending on the details of individual cases.

Returning to the epistemic benefits of psychedelic therapy, it is interesting to contrast the two recent studies of psilocybin for addiction - one on tobacco, the other on alcohol. I have argued that alcoholics who recover through a psychedelic trip will gain an epistemic benefit because their social and other functionality will be restored. The same argument cannot be made for a recovered smoker, since tobacco addiction, despite its adverse physiological consequences, does not tend to compromise socio-emotional and intellectual functioning in the same way as alcohol addiction. What are we to make of this difference?

First, I am not arguing that every therapeutic psychedelic trip is necessarily epistemically innocent - only that some are. Second, however, even the tobacco smoker who kicks the habit via psychedelic mysticism will gain a significant epistemic benefit. There are at least two ways this might occur. The first relates to the finding that psilocybin-induced mystical experiences had by healthy subjects can lead to durable increases in the personality trait of openness to experience. Even for an already well-functioning individual, it is likely that increased openness to experience will cause increases in epistemic functionality analogous to those gained by the recovered alcoholic. More openness means more engagement with the world, more curiosity, and more new experiences of more varied kinds - all potential sources of knowledge[15].

The second way that the tobacco smoker might epistemically benefit relates to the psychedelic experience itself. I have argued elsewhere that psychedelic states can be a means of gaining direct knowledge of the potential of one's own mind and of the contingency of one's sense of self (Letheby 2015). On the first count, neuroscientific evidence suggests psychedelics temporarily decrease constraint or inhibition in the brain, making overall cognitive dynamics more fluid and flexible (Carhart-Harris *et al*. 2014, Tagliazucchi *et al*. 2014). This can amount to a radical and direct discovery that certain ways of thinking or feeling are genuinely possible for oneself. One mescaline subject thought the most important outcome of his first psychedelic experience was "the knowledge and certainty I now have that it is truly possible to attain to a sense of harmony with all creatures and things" (Masters and Houston 1966, 12).

On the second count, one striking feature of some psychedelic states, especially mystical ones, is the experience of 'ego dissolution', in which the ordinary sense of being a unitary, persisting self or 'I' is temporarily diminished or abolished (Pahnke 1969, Carhart-Harris *et al*. 2014). Various philosophers have defended the view that the self as we ordinarily experience it does not exist (Metzinger 2011). Moreover, attaining direct, experiential knowledge of its non-existence is a central goal of Buddhist meditation (Albahari 2014). Ordinarily, the idea of experience without a sense of self is difficult to understand and may even seem incoherent. However, some meditation practitioners and psychedelic subjects become directly acquainted with the contingency of their sense of self. The felt 'I' may be a ubiquitous feature of human consciousness, but the phenomenology of such altered states as these suggests it is not necessary - and this is a striking and significant discovery to make.

So even if alcoholics stand to benefit more, those who break a tobacco addiction via psychedelic mysticism may still derive a significant epistemic benefit, both in virtue of durably increased openness to experience, and in virtue of discoveries about their own mind made during the acute drug effects.

More generally, I conclude that psychedelic mystical experiences can cause significant epistemic benefits which are independent of their non-naturalistic metaphysical contents. These benefits are of two kinds: direct benefits, in the form of knowledge gained during the psychedelic experience itself; and indirect benefits, in the form of improved epistemic functionality after the psychedelic experience. This establishes that these cognitive states meet the Epistemic Benefit condition. I turn now to the No Alternatives condition.

The No Alternatives Condition

Based on the evidence available to date - which is admittedly limited - the efficacy and rapidity with which controlled psychedelic use can change personality and alleviate psychiatric distress is, in many cases, unique (Young 2013). This means that when we consider the epistemic benefits gained by a psychedelically treated alcoholic as a consequence of their restored cognitive and socio-emotional functioning, there is no known alternative cognitive process which will deliver those benefits with such high probability or so rapidly. The antidepressant efficacy of the (non-classic) psychedelic anaesthetic ketamine provides a good illustration of this. Some researchers think ketamine could be important in cases of suicidal depression because it alleviates depressive symptoms within hours, rather than the timeframe of weeks or months required for standard pharmacological or cognitive antidepressant therapies (Vollenweider and Kometer 2010, 2). To put it starkly, if someone is about to take their own life, a therapeutic psychedelic experience may be the only cognitive process which will lead them to keep living and learning. One classic text on the phenomenology of psychedelics describes such a case: a subject who had decided to commit suicide before he underwent a death-and-rebirth experience in the LSD trip which was his last ditch effort (Masters and Houston 1966, 188-189).

It is true, on the other hand, that depression in particular is a condition for which rapid and effective non-psychedelic treatments - such as electroconvulsive therapy (ECT) and repetitive transcranial magnetic stimulation (rTMS) - exist (Ren *et al*. 2014). So it may be that some cases of antidepressant psychedelic therapy would not provide *uniquely* rapid access to indirect epistemic benefits consequent on restored socio-emotional functionality. These specific psychedelic states would then fail to qualify for epistemic innocence - at least, they would fail to do so in virtue of their indirect epistemic benefits. However, they might still qualify in virtue of their direct epistemic benefits. Further, depression-alleviating psychedelic states may provide uniquely rapid access to indirect epistemic benefits in some of the significant proportion of patients who do not respond to alternative rapid treatments (*ibid*.). Of course, my argument in this paper focuses on the epistemic innocence of trips occasioned by *classic* psychedelics, and it is as yet unclear whether drugs of this class have significant antidepressant potential (though see Baumeister *et al*. 2014, Osório *et al*. 2015).

When alternative rapid treatments for conditions such as depression are available, and a given patient has a good chance of responding to such treatments, does this mean that a psychedelic treatment taken by such a patient would not be epistemically innocent? Not necessarily. As mentioned in the preceding paragraph, even if alternative routes to psychedelics' indirect epistemic benefits are available, there may still be no alternative route available to their direct epistemic benefits. In this case, a psychedelic state still would yield significant and otherwise unavailable epistemic benefits; would still, that is, be epistemically innocent. This is not to say that the psychedelic treatment should therefore be preferred. Establishing epistemic innocence is the beginning, not the end, of such a practical deliberation, which must take into account all the kinds of facts mentioned in my earlier discussion of epistemic risk.

There is at least one kind of case in which a psychedelic treatment might fail to be epistemically innocent: that where the patient has already had multiple noteworthy psychedelic experiences. Such a patient might well already have the kinds of direct knowledge of the mind and the sense of self afforded by psychedelics, and in that case another psychedelic experience would be less likely to afford unique access either to indirect *or to direct* epistemic benefits. Above I speculated that repeated and uncontrolled psychedelic use might carry greater epistemic risk. Now I am suggesting that (excessively) repeated psychedelic use might promise lower epistemic benefit. Alan Watts famously said of the psychedelic experience: "If you get the message, hang up the phone" (Watts 1962). The implicit suggestion, which I am tentatively endorsing, is that there is a point at which the important knowledge to be had from psychedelics has already been gained and so the epistemic value of further use is considerably less.

I am endorsing this suggestion only tentatively because there is some evidence to the contrary. Veterans of dozens or even hundreds of ceremonial ayahuasca sessions claim still to learn something new and important with each ingestion, or with most ingestions (Shanon 2002). What can be said conclusively is that these are the conditions that would have to be met for a particular instance of psychedelic therapy to *fail* the epistemic innocence test: not just availability of alternative routes to indirect epistemic benefit, but the lack (or low probability) of direct epistemic benefits uniquely available via the psychedelic route.

But one might wonder whether the direct benefits are in fact *uniquely* available via the psychedelic route. It could be objected that meditation practice can plausibly yield some of the direct epistemic benefits which I have argued may result from psychedelic ingestion, such as knowledge by acquaintance of the potential of the mind (Kornfield 1979, Delmonte and Kenny 1987) and of the contingency of the sense of self (Brewer *et al*. 2013). However, even if so, this method is slower and less reliable than psychedelics (Harris 2014). If an agent at a particular point in time is on the verge of undergoing a controlled psychedelic session, then they will begin to reap the epistemic benefits of doing so within a matter of hours. They would not reap the same epistemic benefits *at that time* if they decided to begin a meditation practice instead.

One worry which might arise at this point is that my discussion of the No Alternatives condition has focused not on whether the epistemic benefits of psychedelics are available via any alternative means whatsoever, but on whether they are available via any equally reliable and rapid means. This might seem to be a problematic misinterpretation of the condition as presented by Bortolotti *et al*.16 To this I respond, firstly, that the focus on the reliability or probability with which different methods deliver epistemic benefits is an unavoidable consequence of the voluntary nature of psychedelic therapy. When the concern is a practical one about whether individuals should choose to enter into epistemically costly or risky cognitive states, there is no choice but to consider the probabilities of the various costs and benefits which might be involved. The notion of an available alternative which *will* (without fail) yield the same benefits is shown to be an idealization by the forward-looking, practical nature of the present case. When reasoning about actions with uncertain future results, epistemic or otherwise, we cannot but trade in probabilities.

Secondly, the No Alternatives condition as originally formulated is somewhat ambiguous with respect to whether the alternative cognitive process *or its resultant benefits* must be unavailable at the time. If, as suggested above, meditation does provide some of the same direct epistemic benefits as psychedelics, then the objection is correct: strictly speaking, there are alternative cognitive processes *available to the agent at the time* which yield the same epistemic benefits. But such a strict interpretation of the condition may not capture what is most important in cases where one process takes hours to yield these benefits while another takes weeks, months, or years. The contrast between psychedelic and traditional antidepressant therapies shows that such a time difference can be practically as well as epistemically consequential. All this suggests either that the No Alternatives condition should be understood to refer to the availability of epistemic results, rather than of the processes which deliver them, or at least that the two possible interpretations of the condition should be borne in mind and disambiguated on a case-by-case basis.

1. Clearly the transformative process cannot be entirely transparent - subjects may be directly aware of the conscious mental states involved, but not of the neural and sub-neural mechanisms causing and/or constituting those states.
2. I take cognitive neuroscience to have explanatory, not merely descriptive, ambitions. As such, even if it were successful in thoroughly charting the neural correlates of consciousness (no small achievement) it would nonetheless have partially failed unless it could also provide an naturalistic explanatory bridge between those correlates and the qualitative character of conscious experience.
3. Strictly speaking, it is psilocin, the dephosphorylated metabolite of psilocybin, which is biologically active - but this loose way of speaking is common and harmless.
4. It could also be true even if the drug experience causes benefits only indirectly, by causing the adoption of new beliefs which themselves cause benefits. I suspect this is not the case, but I will not argue for that claim here.
5. It should be clear that the same point cannot be made with respect to some subjects' beliefs that they have glimpsed non-natural realms. Certainly, one possible explanation of the formation of those beliefs is that they are true - but that explanation is non-naturalistic and hence unavailable within the methodological parameters of my project.
6. Of course, on naturalism, such phenomenal differences as these amount to differences in neural activity. On naturalism, an altered state of consciousness is nothing other than a transient global alteration to neural information processing. My conjecture that the altered state is the therapeutic agent just amounts to saying that therapeutic results are caused by these dramatic, widespread information processing changes, rather than by some direct (e.g. intracellular) effect of the drug which (a) occurs invariably given a sufficient dose and (b) is insensitive to the details of *how* global information processing is differentially altered by particular ingestions.
7. I am grateful to Philip Gerrans for this suggestion
8. Recall: on naturalism, the experience - i.e. the altered state of consciousness - just is the alteration to global neural information processing; in this case, disinhibition of other regions consequent on DMN disintegration.
9. I do not intend to import all the details of Russell's (1910) original analysis of knowledge by acquaintance, but I take it the

intuitive contrast with 'second-hand' knowledge by description or testimony is clear enough.

10. By 'model' I mean something like 'representation encoded by patterns of neural activation' - in this case, a representation whose contents contribute to phenomenal consciousness. I deliberately remain agnostic on details of representational formats, coding schemes, etc.
11. 'Modal knowledge' is a philosophical term for knowledge about possibility, necessity, and so forth.
12. For helpful feedback on earlier versions, I am grateful to Gerard O'Brien, Jon Opie, audiences at the University of Adelaide Philosophy Postgraduate Colloquium and the Australasian Association of Philosophy annual conference, and two anonymous referees for the Journal of Consciousness Studies.
13. Where 'epistemic' simply means 'of or pertaining to knowledge'.
14. Though it is highly controversial whether delusions are beliefs. Non-doxastic theorists (e.g. Gerrans 2014) argue that they are not, emphasising their non-belief-like features: they are often held with ambivalence, isolated from an agent's other beliefs, and relatively behaviourally inert. Doxastic theorists, on the other hand, emphasise the belief-like features of delusions, as well as suggesting that non-doxasticists deploy an overly strict or narrow conception of beliefs (e.g. Bortolotti and Gunn 2015).
15. An intriguing question is whether personality traits such as openness to experience bear any interesting relation to the kinds of epistemic virtues discussed by philosophers. (I am indebted to James Morauta for raising this question.) Any attempt to draw such correspondences, however, faces difficult problems concerning how to understand the theoretical and ontological commitments of the Big Five model of personality (Miller 2014) - problems which do not arise for the mere claim that increased openness will typically be accompanied by epistemic benefit.
16. I am indebted to an anonymous reviewer for raising this point.

Conclusion

Evidence for the transformative efficacy and possible therapeutic utility of psychedelics raises intriguing issues which deserve serious attention. Among these is the legitimate concern that we may be "foisting a comforting delusion on the sick and dying". I have applied the concept of epistemic innocence to argue that the situation is more complicated and that despite their potential (albeit not inevitable) epistemic faults, psychedelic states can confer significant and otherwise unavailable epistemic benefits, both direct and indirect. Possible direct benefits include knowledge by acquaintance of the potential of the mind and the contingency of the sense of self. Possible indirect benefits include improved epistemic functionality brought about either by restored cognitive, social, and emotional functionality, or by increased openness to experience. Thus, some psychedelic states are epistemically innocent imperfect cognitions.

This conclusion matters because the epistemic status of psychedelic therapy is highly relevant to policy debates. Some of the psychedelic scientists interviewed by Michael Pollan in the *New Yorker* seem quite unconcerned by the possibility that therapeutically efficacious psychedelic mystical experiences are non-veridical. I think they are right to be unconcerned, but not because the epistemic status of therapies is unimportant.

To appreciate the importance of epistemic issues, consider Nozick's (1974) famous 'Experience Machine' thought experiment. The hypothetical Machine provides users with a lifelong stream of virtual reality experiences as pleasurable, varied, and realistic as could be. It is a common intuition that plugging in to the Machine would be a mistake, and one explanation of this intuition is that we care not only about having pleasant experiences but about having experiences based in reality. Truth and knowledge matter. When some method of attaining well-being depends upon forming false or unsupported beliefs, or refraining from forming true or well-supported beliefs, we tend to view this as a flaw of that method.

Of course, such flaws are not inevitably fatal. This is one of the key points of the talk about epistemic innocence. The point is just that epistemic evaluation matters. So if we are to prescribe an epistemically costly method of attaining well-being, we want to do so because the epistemic costs are outweighed by the overall benefits - not because we have simply ignored the epistemic costs. The scientists interviewed by Pollan may well be correct that the potential non-veridicality of psychedelic mysticism is not a compelling objection to prescribing psychedelic therapy. But this is not because epistemic issues are unimportant. Rather, it is because psychedelic therapy is unlike the Experience Machine in the respects explored in this paper.

Finally, the case of psychedelic therapy helps advance the broader discussion of epistemic innocence. It shows that the concept illuminates a broader range of cases than just acceptable emergency responses, and also illuminates issues concerning voluntary imperfect cognitions. This in turn raises the issue of epistemic risk, and how such risk might be traded off against potential epistemic benefits, as well as pragmatic risks and benefits. Meanwhile, the contrast between psychedelics and prospective alternatives reveals the need for care in interpreting the No Alternatives condition. Most generally, this analysis of psychedelic therapy provides yet more reason to think that the epistemic status of imperfect cognitions is more complex than it might at first appear.

Naturalizing Psychedelic Sprirituality

Statement of Authorship

Title of paper:	Naturalizing Psychedelic Spirituality
Publication status:	Submitted for publication
Publication details:	Under review for Zygon: Journal of Religion and Science. December 2016.
Principal Author	
Name of principal author (candidate):	Christopher Letheby
Contribution to the paper:	Devised the arguments and wrote, proofread, polished, formatted, and submitted the paper.
Overall percentage (%):	100%
Certification:	This paper reports on original research I conducted during the period of my Higher Degree by Research candidature and is not subject to any obligations or contractual agreements with a third party that would constrain its inclusion in this thesis. I am the primary author of this paper.

Date:	

Introduction

One of the biggest philosophical problems of our age is how to respond to the existential anxiety caused by the 'disenchantment of the world' - the transition from a religious worldview to a naturalistic one which eschews transcendent foundations for meaning and value. Some philosophers have suggested that this problem is currently becoming more acute as the results from contemporary neuroscience filter into the zeitgeist, rendering a disenchanted naturalistic conception of human beings ever more unavoidable and undeniable, and leading to a distinctive 'neuroexistentialist' anxiety (Flanagan and Caruso forthcoming, Metzinger 2009).

Various theoretical solutions to this problem have been pursued, often in the form of efforts to 'naturalize' some central pillar of meaning or purpose such as free will or morality (Dennett 1984, Sturgeon 2006). But to (somewhat facetiously) paraphrase Douglas Adams (1979), this is odd because, on the whole, it isn't our theories that are unhappy. I want to explore the prospects for a different, more practical kind of solution, based on a remarkable empirical observation about the conditions under which human beings can regain a sense that life is worth living. I refer to the finding that classic psychedelic drugs such as LSD and psilocybin can, under conducive circumstances, occasion intense experiences leading to lasting psychological benefits - including the amelioration of existential distress resulting from terminal illness (Grob *et al*. 2011, Gasser *et al*. 2014, Griffiths *et al*. 2016, Ross *et al*. 2016). A renaissance of scientific research into an "existential medicine" (Grob 2007, 213) certainly warrants the attention of philosophers interested in the overcoming of disenchantment and nihilism.

There is a problem, however, in that some evidence suggests that the existential re-enchantment occasioned by psychedelics depends crucially on the induction of mystical experiences involving apparent encounters with transcendent non-natural levels of reality (Griffiths *et al*. 2006). If this is so, then psychedelics would seem less a means to making peace with a naturalistic worldview than a means to becoming persuaded of its falsity. In the spirit of the philosophical project of 'naturalizing spirituality', I will argue that such non-naturalistic metaphysical epiphanies are far from the whole story: that there are key elements of psychedelic spirituality which can be practiced by a naturalist in intellectual good faith, and which represent a promising path to re-enchanting the naturalistic world on its own terms.

I will begin, in section 1, by describing the neuroexistentialist predicament, and two possible kinds of solutions to it, in more detail. In section 2 I will describe the potential psychedelic solution and the apparent problem with that. In sections 3 and 4 I will draw on neuroscientific research into the mechanisms of psychedelic-induced transformative experience to argue that there is a naturalistically viable kind of spirituality to be found here. The basic idea is that psychedelics degrade the mechanisms of self-representation in the brain, in some cases allowing subjects to see that the ordinary sense of self is a useful fiction, and in other cases freeing their attention from self-focused concerns leading to the availability of broader perspectives on life. The common thread is that a good deal of existential suffering stems from an excessively rigid focus on and reified belief in a solid and enduring self and its travails. Loosening the bonds of this egocentricity and ego identification, by psychedelics or other means, is one good idea about what naturalized spirituality might amount to, and a promising practical response to neuroexistential anxiety

The Neuroexistentialist Predicament

Naturalism, in its most basic form, is the denial of the existence of non-natural or supernatural entities such as gods, souls, spirits, and non-physical minds. It is a commonplace by now that the gradual transition from a religious to a naturalistic worldview over the past few centuries - due to the rise of modern science, and especially since Darwin - has created a crisis of meaning and value. The growing plausibility of naturalism, which leaves no room for any of the traditional foundations of value, evokes anxiety about what, if anything, could possibly replace those foundations, and how, if at all, we might come to terms with a world devoid of them. This naturalistic crisis is sometimes referred to as the *disenchantment of the world* (Dreyfus and Kelly 2011).

Owen Flanagan and Gregg Caruso (forthcoming) argue that we are currently experiencing a new and distinctive wave of existential anxiety as a result of impressive advances in neuroscience, and the popular dissemination of these findings. It is not that neuroscience has discovered anything new about how disenchanted the naturalistic world is; rather, it is painting a vivid and dramatic picture of what this disenchantment looks like, in the specific and cherished case of human beings. Part of what is hardest to swallow about a naturalistic view of the world, at least for some, is its implication that human beings are ultimately nothing special - a very smart animal, to be sure, but a mere accidentally evolved, cognitively limited, mortal animal none the less. We have no Cartesian ego, no contra-causal free will, and no eternal destiny. With every new stride in the neuroscientific mapping of the material bases of decision making, reward, emotion, and so forth, this reality becomes ever more palpable. And the popularization of neuroscience plausibly heralds the dissemination of this vision beyond intellectual and academic circles into the broader culture, threatening a wholesale and widespread crisis of meaning.

One useful way of conceiving of this situation is in terms of Wilfrid Sellars' (1963) manifest and scientific images of humankind. The manifest image is simply the potentially highly reflective and refined, but nonetheless pre-scientific, conception of what kinds of things human beings are, developed and expressed in the arts and humanities as well as in everyday talk and thought. The scientific image, meanwhile, is the theoretical conception of the nature of human beings delivered collectively by biology, psychology, anthropology and so on - including, most recently and notably, neuroscience. Sellars thought - and others since (e.g. Dennett 2013) have agreed - that dealing with the various apparent conflicts between the manifest and scientific images is one of the central tasks, if not the central task, of philosophy today. It is an important and difficult business trying to "know [our] way around" (Sellars 1963, 1) a world in which our most successful epistemic enterprise seems to keep telling us that we are something very different from what we automatically and perhaps unavoidably take ourselves to be.

Flanagan and Caruso (forthcoming) describe the manifest image as incorporating commitments to such things as transcendent foundations for meaning, contra-causal (or 'libertarian') free will, human exceptionalism, the immortality of the soul, and so forth. Doubtless there is considerable inter-individual and cross-cultural variation in the precise content of the manifest image. Nonetheless it seems plausible that most of us operate at least tacitly with an individual and collective self-conception that is significantly at odds with the disenchanted scientific image.

The philosophical attempt to grapple with this inter-image conflict is exemplified in the 'naturalizing' industry that has sprung up in the last several decades. The basic strategy is to take some component of the manifest image, such as free will, or objective moral requirements, that seems inadmissible to the scientific image, and give an analysis or account of the phenomenon in question which shows that it can be a real and unmysterious part of a purely naturalistic world. Such responses attempt to demonstrate theoretically that the problem is not as bad as it seems, because the naturalistic world is not as devoid of cherished foundations for meaning and purpose as we thought it was.

There is nothing wrong with this kind of strategy, but an interestingly different sort of response is available. This is exemplified by the project that Flanagan (2007) has called *naturalistic eudaimonics* (from the Greek *eudaimonia*, usually translated as 'human flourishing') - an empirically based inquiry into the conditions under which human beings can flourish and live meaningful lives. This project arises from a recognition that the neuroexistentialist predicament, while it may have its genesis in our theoretical beliefs about how things are, is not merely a theoretical or intellectual problem - it is a practical, emotional problem, a problem of living. A reflective person who is struggling with the problem of nihilism and disenchantment in our neuroscientific, post-Darwinian age wants to know: how can I, or how can we, live well and find meaning and fulfillment, given the kinds of creatures it seems that we are and the kind of world it seems that we inhabit? Of course, one possible answer to that question is: by gaining a theoretical, philosophical understanding and appreciation of how phenomena such as morality and freedom fit into a naturalistic world. But the eudaimonic approach does not presuppose that the only or the best answers will take this form. Rather, it starts with the question: how do human beings achieve meaning, fulfillment and flourishing, when in fact they do?

This is similar in spirit to the methodology of the movement known as *neurophilosophy* (Churchland 1989). Practitioners of neurophilosophy - neurophilosophers - seek to bring the results of neuroscience to bear on traditional philosophical questions. For instance, a neurophilosopher interested in understanding the nature of morality might start her inquiry by looking at neuroscientific evidence concerning moral judgment: its alterations under various conditions, its relations to other cognitive capacities, its neural substrates, and so forth (Churchland 2011). She would then use these facts as a basis for philosophical conclusions about morality.

Here I want to suggest that a helpful contribution to Flanagan's naturalistic eudaimonics could be made by a neurophilosophical inquiry into certain kinds of experiences which are repeatedly referred to as 'spiritual', and which sometimes seem to help those who undergo them to overcome existential anxiety and find meaning in life. A golden opportunity for such an inquiry currently exists, in the form of a recent surge of cognitive neuroscience research into pharmacological agents which reliably evoke such experiences - namely, classic psychedelic drugs.

An Existential Medicine?

Patients with terminal illness undergo intense suffering of many kinds, not least of which is the sense that life is worthless or meaningless in light of their impending mortality. Powerful, effective, and reliable methods of ameliorating this existential distress have thus far proven elusive (Henoch and Danielson 2008). Hence, the following quotations from terminal patients are noteworthy: "It was less about my illness. I was able to put it into perspective. ... Not to see oneself with one's sickness as center. There are more important things in life. ... The evolution of humankind for example. ... Your Inner Ego gets diminished, I believe, and you are looking at the whole ..." (Gasser *et al*. 2015, 62). And: "Dying is as usual or unusual as life itself. You cannot separate it. I simply have to familiarize myself with the idea and the process" (*ibid*.).

These patients are describing experiences and insights they had while intoxicated by the infamous drug lysergic acid diethylamide (LSD), as subjects in the first controlled study of LSD-assisted psychotherapy in over four decades. The 12 subjects in this study showed reductions in anxiety for 12 months after two LSD sessions (Gasser *et al*. 2014). Similar results were found in an earlier pilot study using psilocybin, another classic psychedelic, to treat anxiety relating to terminal illness (Grob *et al*. 2011). More recently, these results have been replicated in two larger, double-blind, placebo-controlled studies of psilocybin treatment for psychological distress in life-threatening cancer (Griffiths *et al*. 2016, Ross *et al*. 2016). As a result of these studies, the treatment of psychological distress in terminal illness is now the best-studied therapeutic application of classic psychedelics (Nutt 2016).

So, we have evidence for thinking that experiences occasioned by classic psychedelics can help people to deal with a sense of the meaninglessness of life in light of mortality. This suggests the possibility of an analogy with other kinds of existential anxiety: could psychedelics offer part of a solution to neuroexistentialist anxiety and the crisis of meaning resulting from the disenchantment of the world? This kind of solution might take two forms: either the careful, controlled administration of psychedelics (in a vastly different legal, regulatory and cultural situation from that which exists today) to volunteers afflicted by neuroexistentialist anxiety, or the study of the mechanisms of psychedelic therapy in the hopes of finding non-pharmacological routes to their salutary psycho-existential effects.

Before I explore this possibility in more detail, a little background is in order. LSD and psilocybin are both 'classic' psychedelics, meaning that they alter consciousness mainly by agonism of the serotonin 2a receptor. Other famous exemplars of this class include mescaline (from the peyote cactus) and dimethyltryptamine (DMT, an ingredient in the South American beverage ayahuasca), both of which have long histories of traditional religious use (as does psilocybin.) I will confine my discussion here to these classic, serotonergic psychedelics, and reserve the term psychedelic for them alone, omitting other drugs which have been called 'psychedelic' on phenomenological grounds despite different mechanisms of action (e.g. ketamine, *Salvia divinorum*, and MDMA or 'Ecstasy'; Sessa 2012).

From the 1940s to the 1960s there was widespread scientific interest in psychedelics following Albert Hoffman's discovery in 1943 of the potent effects of LSD. The propensity of psychedelics to induce experiences which subjects described in spiritual or mystical terms was one factor responsible for this interest (Dyck 2008). It should be noted that another distinctive property of psychedelics is the extreme variability of their effects; as such, it is certainly not the case that every psychedelic experience is of a spiritual nature (Masters and Houston 1966). However, experiences of this broad kind seemed to keep happening unbidden, even when the drugs were being studied for quite different reasons, such as their putative capacity to mimic psychosis (Mangini 1998).

Since the early days of psychedelic science there has been a debate over the credentials of drug-induced mystical-type experiences: whether they are identical or different, equivalent or inferior, to 'genuine' mystical experiences which occur spontaneously or through religious practice (Zaehner 1958, Smith 1964, Walsh 2003). However, it is beyond doubt that many psychedelic experiences possess core phenomenological features characteristic of non-drug mystical states, such as the dissolution of the sense of self, a feeling of unity with the cosmos, ineffability, and profound joy and peace (Pahnke 1969, Griffiths *et al*. 2006). This similarity was emphasized by intellectuals such as Aldous Huxley (1954), Alan Watts (1962) and Timothy Leary (Leary *et al*. 1964), who explicitly connected the psychedelic state to the consciousness alterations aimed at by Eastern meditative practices, laying the conceptual groundwork for the psychopharmacological mysticism of the 1960s counterculture. Many psychedelic mystics of the era became dedicated practitioners, sometimes teachers, of meditation (Dass 1971, Osto 2016).

Ultimately, psychedelics became the focus of intense sociopolitical controversy due to widespread use by members of the counterculture, leading to their prohibition and the subsequent virtual cessation of human research for some decades (Dyck 2008). Since the 1990s, however, a slow but steady 'renaissance' of scientific interest in psychedelics has occurred (Sessa 2012). As well as establishing the feasibility and safety of careful and controlled psychedelic administration, this new wave of research has begun revisiting earlier claims for the therapeutic and transformative efficacy of psychedelics.

I already mentioned the four studies published to date of LSD and psilocybin in the treatment of anxiety resulting from terminal illness. Besides these, small studies have also investigated the potential of psilocybin, LSD, and ayahuasca to treat addiction, obsessive-compulsive disorder, and depression, with uniformly promising albeit tentative results (reviewed in dos Santos *et al*. 2016a). Meanwhile, studies in healthy non-patient populations have found that mystical-type experiences induced by psilocybin can lead to positive personality change lasting over a year (MacLean *et al*. 2011). One frequent result, both in these studies of healthy subjects and in studies of therapeutic applications, has been that the degree of mystical experience predicts the degree of long-term psychological benefits. This echoes results from earlier, often less methodologically rigorous mid-20th century studies (Pahnke 1969). So there is mounting evidence that classic psychedelics can durably improve quality of life by inducing mystical or spiritual experiences, bolstering the case for them as a potential remedy to neuroexistential anxiety and disenchantment.

There is a problem, however, in that such mystical experiences almost by definition involve the apparent apprehension of a transcendent, non-natural reality or 'Ground of Being' of precisely the kind that is denied by a naturalistic worldview. If inducing such experiences really is the means whereby psychedelics improve individuals' psycho-existential situations, then it would seem that these drugs are suited not to reconcile subjects to naturalism but to persuade them of its falsity. This is a serious reason to doubt whether my proposed neurophilosophical response to the neuroexistentialist predicament can even get off the ground.

Naturalistic Entheogenics

To some - especially those who have themselves benefited from a psychedelic mystical experience - it may seem that there is little to worry about here. If psychedelic mysticism can solve our neuroexistentialist problem by showing us that there is no problem, because a transcendent foundation for meaning exists after all, then so much the better!

The problem is that those who are impressed by the theoretical arguments for naturalism will be unimpressed by this response. The arguments for naturalism strike many philosophers as very persuasive, and if these arguments are sound - if naturalism is true - then the apparently non-naturalistic dimensions of mystical experience must be illusory. I am not undertaking a defense of naturalism here, but rather asking: on the (plausible) supposition that naturalism is true, is there a way that we can existentially come to terms with that fact? It should be clear that taking non-naturalistic mystical realizations at face value cannot support an affirmative answer to this question. Becoming convinced that a fact does not obtain is not coming to terms with it.

My psychedelic response to the neuroexistentialist predicament is intended as a contribution to the project of eudaimonics, which Flanagan and Caruso explicitly define as an inquiry into the conditions of flourishing for beings "whose self understanding includes the idea that [a naturalistic world] is the only kind of world that there is" (forthcoming, 15). The key question then becomes: is it true that the basic way in which psychedelic experiences alleviate psychological and existential distress is by convincing subjects that some more comforting metaphysical worldview than naturalism is correct? I am going to argue that it is not: that there are core aspects of the psychedelic transformative process, even in intense peak experiences, which are independent of apparent non-naturalistic metaphysical apprehensions. Moreover, I am going to suggest that even some of the aspects of psychedelic experience which prompt the description *spiritual* fit this naturalistic bill.

At this point my project connects with recent philosophical endeavors to naturalize spirituality, as distinct from religious belief. The very idea of something worth calling 'spirituality' that is both separable from religion and consistent with a naturalistic metaphysics may sound strange at best, contradictory at worst. But there is a growing recognition that one common use of the word *spiritual* denotes something that is distinct from religion, that has more to do with a personal quest for meaning based on transformative practice and experience, specifically experience of a self-transcendent nature. And proponents of naturalistic spirituality have been arguing that at least some of these practices and experiences can be pursued and cultivated in a way that is compatible with both intellectual honesty (Metzinger 2014) and a commitment to naturalism (Stone 2012). My aim here is to extend these efforts into the psychedelic sphere.

The neologism *entheogen* (generating the divine within) has become popular as a way of referring to psychedelics when used specifically for spiritual purposes (Ruck *et al*. 1979, Smith 2000). It is not too much of a stretch to say that the history of psychedelic research has been witness to a tension between an 'entheogenic conception' of the drugs and a seemingly opposing 'psychotomimetic/hallucinogenic conception' favored by less mystically and more naturalistically inclined thinkers. This latter conception sees psychedelics as fundamentally agents of misrepresentation and cognitive distortion, lacking significant epistemic value; according to Nicolas Langlitz's (2012) anthropological studies of psychedelic science, such a conception is implicit in much of the language used to frame model psychosis research. But Langlitz notes a tendency to rapprochement on the part of certain psychedelic researchers who embrace what he calls a *mystic materialism*. In effect, I am going to be suggesting that such a view is legitimate, by trying to naturalize the entheogenic conception of psychedelics.

I will not be assuming or defending any specific philosophical account of naturalistic spirituality. Instead, in keeping with my neurophilosophical orientation mentioned earlier, I propose that we take a 'bottom-up' approach to understanding the phenomenon: look first at what is known neuroscientifically about the kinds of experiences and practices in question, and try to identify the features and qualities which cause people to describe them as 'spiritual'. We can come to understand what spirituality is, and whether and how it is compatible with naturalism, by looking closely at the details of paradigm cases of putatively spiritual phenomena. And subjects' overwhelming tendency to describe them in such terms suggests that psychedelic peak experiences certainly fit the bill.

Even though I will not endorse any of the existing theories, I will note that one ground for optimism about naturalizing entheogenics is that many common features of psychedelic experiences are also common themes in theories of naturalistic spirituality. Among these are wonder and awe, especially at the natural world (Goodenough 1998), love of life (Solomon 2002), and dissolution or transcendence of the individual sense of self (Harris 2014, Simpson 2014).

Ursula Goodenough proposes that reflective contemplation of scientific descriptions of nature, along with philosophical mysteries such as why there is something rather than nothing, can evoke deeply thoughtful but also affective responses of wonder and reverence at the vastness, complexity, and improbability of the natural world and of our own existence. Part of this process involves broadening our perspective and learning to see the individual self in a much larger spatiotemporal context (Goodenough 1998, Goodenough 2001, Goodenough and Woodruff 2001). Robert Solomon's account of naturalistic spirituality echoes many of these themes, recommending a thoughtful (intellectually well-grounded) sense of love and reverence for life as it is, and a sense of existential gratitude grounded in an appreciation of the vulnerability and contingency of our own lives. Like Goodenough, Solomon (2002) suggests that a key part of the spiritual process is the broadening of perspective beyond the concerns of the individual self.

While these theories of spirituality recommend transcending the self by a broadening of perspective, Sam Harris (2014) holds that spirituality consists precisely in attaining and then deepening a direct, experiential insight into the nonexistence of the self. Of course, Harris does not deny that conscious biological organisms as constantly evolving processes exist. But the claim here, common to many mystical traditions and articulated most clearly in Buddhism (Albahari 2006), is that we tacitly and habitually take ourselves to be something more than a constantly changing process - a persisting and indivisible subject of experience sharply distinct from the rest of the world. Our acceptance of this 'self-illusion' is claimed to give rise to much psychological suffering, and as such, seeing through the illusion is prescribed as a remedy.

As Harris is at pains to emphasize, despite the stronger metaphysical commitments of some schools of Buddhism, there is nothing non-naturalistic about this core psychological claim (cf. Simpson 2014). Ultimately, I will suggest that psychedelics dissolve (or weaken) the self-illusion, and broaden our perspectives, by the same basic mechanism. Evidence to be discussed below suggests that the neurocognitive systems underpinning the sense of self are the same ones that constrain cognition in accordance with the goals and interests of that self, and disrupting these systems both diminishes the felt sense of self and liberates attention from bondage to self-centered concerns. Thus, despite their differences in emphasis, there is plausibly a mechanistic unity to the varieties of 'de-selfing' recommended in these various accounts of naturalistic spirituality.

A second ground for optimism is that some psychedelic researchers describe the entheogenic transformative process in terms which do not sound unambiguously non-naturalistic. For instance, Charles Grob, describing the use of psilocybin for anxiety relating to terminal illness, says this: "Under the influence of hallucinogens, individuals transcend their primary identification with their bodies and experience ego-free states before the time of their actual physical demise, and return with a new perspective and profound acceptance of the life constant, change … This implicit acceptance of the inevitable cycles of life leads to a drastically altered approach to what time is remaining without the panic, fear, pain, and dependency that were previously so overwhelming" (Grob 2007, 213).

Of course, references to transcending a "primary identification" with the body, and to experiencing "ego-free states", may sound somewhat questionable to naturalistic ears. However, as I have indicated, I think that there is perfectly plausible naturalistic sense to be made of such talk. In order to establish this, I turn now to recent cognitive neuroscience research on the mechanisms of psychedelic transformation.

Mechanisms of Mysticism

Recent fMRI studies of the psychedelic state have provided a fascinating window onto the neurocognitive mechanisms whereby these substances exert their effects on consciousness. Robin Carhart-Harris and colleagues (2012) found, to their surprise, that intravenous psilocybin decreased brain activity, rather than increasing it as had previously been thought. Moreover, the decreases were concentrated mainly in the famous Default Mode Network (DMN), a network of densely connected brain regions, most active in resting task-free conditions, which has repeatedly been implicated in generating the sense of self, as well as in mind-wandering, mental time travel (the simulation of past and future events), and theory of mind (the attribution of mental states to self and others; Raichle *et al*. 2001, Spreng and Grady 2010).

The decrease in activity and connectivity within the DMN was accompanied by a global increase in the unpredictability of the patterns of functional connectivity throughout the brain, quantified by the information-theoretic construct of *entropy*. Carhart-Harris *et al*. (2014) used these findings to argue that the core mechanism of psychedelic consciousness-alteration is downregulation of the DMN, which they claim implements ego-functions and serves as a 'conductor' of the global neurocognitive orchestra, constraining the quality of cognition to maintain an efficient and adaptive functional profile. Disruption to the DMN disrupts its ability to constrain cognition and allocate resources in a goal-driven fashion, and this explains many key features of the psychedelic state such as the detaching of attention from personal concerns and the sense of 'mind expansion' resulting from a broadening and loosening of attention.

The dissolution of the ego or sense of self is a quintessential feature of psychedelic experiences, particularly mystical ones, which seems explicable on this model too. Remarkably, subjective ratings of ego dissolution in these studies correlated strongly with decreases in alpha oscillations in the posterior cingulate cortex (PCC), a key DMN hub whose activity is also decreased in states of 'effortless awareness' achieved by meditation (Brewer *et al*. 2013). A study of cortical thickness in long-term religious users of ayahuasca found thinning in the PCC relative to matched controls. This thinning correlated with the extent of prior ayahuasca use, as well as with psychometric scores for the personality trait of 'self-transcendence', and was not accompanied by any impairments to neuropsychological function (Bouso *et al*. 2015). Combined with the finding that acute ayahuasca intake increases capacities cultivated in mindfulness meditation, such as psychological 'decentering' and a nonjudgmental perspective on inner experience, this set of observations is intriguing to say the least (Soler *et al*. 2016).

Carhart-Harris *et al*. (2014) argue that ego dissolution and entropy elevation both result essentially from psychedelic-induced downregulation of the DMN and related networks. Discussing the therapeutic effects of psychedelics, they note that many of the conditions indicated - addiction, depression, anxiety, and obsessive-compulsive disorder - are characterized by cognitive rigidity. They propose that the psychedelic-induced entropy elevation shakes the cognitive system out of its rut, breaking down entrenched patterns (i.e. habits) of thought, feeling, and perception, creating the possibility of forming new, more adaptive patterns by potentiating novel and under-utilized pathways. This claim is further supported by the recent finding that the degree of entropy elevation induced by LSD predicted the magnitude of increases in the personality trait of Openness to Experience displayed by healthy subjects a fortnight later (Lebedev *et al*. 2016). This is the same personality trait that was increased following psilocybin-induced mystical experiences (MacLean *et al*. 2011).

Many questions remain unanswered in the cognitive neuroscience of psychedelics. Not all neuroimaging studies have produced consistent results (see dos Santos *et al*. 2016b for a review). However, the theoretical speculations I have just described represent a plausible synthesis of current mechanistic knowledge which is consistent with phenomenological observations and provides a useful basis for thinking about the spiritual dimensions of the experience.

Consider ego dissolution, a prominent element of mystical experience. As I mentioned earlier, it is a plausible naturalistic view that the self or 'I' as we ordinarily experience it does not exist - that the sense of self is a useful fiction created by the brain (Metzinger 2003). Buddhism contends that our belief in the reality of this fictitious entity, and our subsequent attachment to its fortunes, is the source of all psychological suffering (Albahari 2006). The DMN has repeatedly been implicated in both mind-wandering and the sense of self, and empirical studies have shown that time spent mind-wandering, and functional connectivity within the DMN, both predict unhappiness. Matthew Killingsworth and Daniel Gilbert (2010) used an experience-sampling methodology implemented by a smartphone app to track participants' self-reported levels of mind-wandering vs. mindfulness, and happiness vs. unhappiness, throughout the day. They reported that mind-wandering was both extremely common and strongly correlated with state unhappiness. Meanwhile, Luo *et al*. (2015) found that high levels of functional connectivity within the DMN as revealed by resting-state fMRI were correlated with trait unhappiness as determined by psychometric questionnaires (cf. Machado and Cantilino 2016). There is no need to swallow Buddhist psychology whole to entertain the view that excessive rumination about the self and its travails causes much needless distress.

Granted this much, the ego dissolution experience may well involve a genuine insight, a veridical apprehension of the fact that our sense of being a discrete and persistent 'I' arises out of a habitual process of creating models and spinning narratives about an ultimately fictitious entity (Dennett 1991, Simpson 2014). And if breaking the cycle of self-focused rumination can help to alleviate anxiety and depression in general, then it theoretically ought to work for existential anxiety in particular. After all, existential anxiety, as much as any other kind, intrinsically involves a focus on the prospects of a subject, a self, in a threatening predicament.

There is an obvious worry about the very idea of an ego dissolution experience: that it is conceptually incoherent to claim that a subject has a memory of an episode during which their sense of self was absent (Metzinger 2005). It is possible to reply to this by suggesting that, despite appearances and intuitions, the cognitive processes supporting self-representation and autobiographical or episodic memory encoding are dissociable. But further empirical research would be needed to determine this. A simpler line of response is to concede that probably some minimal sense of self remains in most if not all psychedelic experiences (Pahnke 1969, Shanon 2002). Even if that is true, clearly the dramatic alteration or diminution of the ordinary sense of self is enough to have a profound impact on a subject.

Moreover, there is reason to think that a 'mere' loosening, rather than dramatic diminution, of the sense of self can have a profound effect. In the recent study of LSD in terminal illness, full-blown mystical experiences were not generally observed. Instead, reductions in anxiety were brought about by emotional, not metaphysical, peak experiences, characterized by loosening, not disintegration, of ego boundaries (Gasser *et al*. 2015). The researchers suggest that the reductions in existential angst were brought about by a liberation of attention from its bondage to personal concerns, enabling patients to access new, broader perspectives on their predicament: "Throughout an altered basic emotional experience, loosening of ego functions combined with pronounced self-referential processing of significant (intellectual/emotional) content, patients may gain a new perspective on themselves and a reduction of ruminations and ego-centeredness" (*ibid*., 9).

One patient in this study commented that when the sense of ego is diminished, "you are looking at the whole ... you are indeed starting to build relations with plants or with the entire living world around. You think less about yourself, you are thinking - across borders" (*ibid*., 6).

These observations suggest a mechanism, distinct from but continuous with the mechanisms of full-blown mystical or ego dissolution experiences, whereby psychedelics could induce the kinds of experiential qualities emphasized in Goodenough's and Solomon's theories of naturalistic spirituality: broader perspectives, wonder and awe, and appreciation of life. Recall, Carhart-Harris *et al*. propose that the DMN, as part and parcel of the 'ego functions' it implements, serves to constrain the quality of cognition, allocating attentional resources to stimuli in accordance with an organism's goals. We have seen that an excessive focus on the self and its travails, existential or otherwise, plausibly underpins much psychological distress, existential or otherwise. But this excessive focus also consumes attentional resources which otherwise could be devoted to non-self-related cognitive contents, such as reflection on the natural world and the human condition.

Indeed, psychedelic phenomenology suggests that when attention is freed from a bondage to self-related concerns by the downregulation of 'selfing' systems in the brain, these are exactly the kinds of places that it tends to go. It is very common, even in non-mystical states, for psychedelic subjects to report feeling a sense of kinship with the natural world, or wonder and awe at the miracle of existence in general and human existence in particular (Shanon 2002). In his literary analysis of narrative reports of psychedelic experience, R. A. Durr (1970) argues that changes to attention in the psychedelic state lead to the same kind of (essentially imaginative) appreciation of life that is expressed in verse by the Romantic poets. When the bonds of self-concern are weakened psychopharmacologically, "looking at the whole [and] starting to build relations with plants or with the entire living world" becomes, it would seem, not only possible but probable.

The philosopher Jesse Prinz (2014) proposes an account of the cognitive dynamics of aesthetic appreciation which seems applicable to the broader kind of appreciation of life resulting from psychedelic states. On Prinz's view appreciation amounts to a positive feedback loop between attention and wonder. Attention alights on some element of a visual object which evokes wonder, and the sense of wonder leads to increased attention to the visual element, and so forth. Perhaps by disrupting the analogous but deleterious positive feedback loop between existential anxiety and excessive attention to the existential predicament of the self, psychedelics create space for other, more beneficial attentional cycles to arise (cf. Nichols *et al*. forthcoming).

Everything I have said so far points to a central common element in mystical and non-mystical psychedelic experiences: the weakening of the ego by disruption to the DMN, whether this results in an 'ego dissolution' experience or a broadening of attention and loosening of cognition. In either case, something occurs that could reasonably be called mind-expansion, a liberation of focus from a narrow, rigid and maladaptive preoccupation with a reified self and its predicament. There is evidence that this basic process is important to the therapeutic and transformative effects of psychedelics. And while clearly compatible with a naturalistic outlook, a transformative process which involves broadening perspective beyond the individual self, and apprehending its interconnectedness, transience, and ephemerality, surely deserves the name *spirituality* if anything does.

Conclusion

The disenchantment consequent upon naturalism, particularly in its current neuroexistentialist incarnation, is a pressing problem deserving of serious philosophical attention. A plethora of theoretical solutions have been proposed, but it is worth investigating practical, psychological solutions to this problem too, via a neurophilosophical inquiry into methods of re-enchantment. The renaissance of scientific research into psychedelics, the 'existential medicine', constitutes an extremely promising avenue for this inquiry, but the apparent centrality of non-naturalistic mysticism to psychedelic transformation poses a prima facie obstacle. I have argued that despite appearances, entheogenic spirituality can be naturalized, by understanding that much of its transformative efficacy is a matter of breaking the spell of narrowly self-focused rumination, temporarily disrupting the mechanisms of self-representation and liberating attention from bondage to personal concerns. This disruption and liberation afford an opportunity to access new perspectives, see oneself and one's concerns in a broader context, and develop a sense of wonder and appreciation for life.

Anatomy of an Avatar: Ego Dissolution in Psychedelic Experience

Statement of Authorship

Title of paper:	Anatomy of an Avatar: Ego Dissolution in Psychedelic Experience
Publication status:	Submitted for Publication
Publication details:	Under review for Neuroscience of Consciousness, December 2016.
Principal Author	
Name of principal author (candidate):	Christopher Letheby
Contribution to the paper:	Contributed equally to devising the arguments and writing the paper; additionally proofread, polished, formatted, referenced, and submitted the paper.
Overall percentage (%):	55%
Certification:	This paper reports on original research I conducted during the period of my Higher Degree by Research candidature and is not subject to any obligations or contractual agreements with a third party that would constrain its inclusion in this thesis. I am the primary author of this paper.
Signature:	
Date:	

Co-Author Contributions

By signing the Statement of Authorship, each author certifies that:
i) the candidate's stated contribution to the publication is accurate (as detailed above);
ii) permission is granted for the candidate to include the publication in the thesis;
and
iii) the sum of all co-author contributions is equal to 100% less the candidate's stated contribution.

Name of co-author:	Philip Gerrans
Contribution to the paper:	Contributed equally to devising the arguments and writing the paper.

Date:	

Introduction

In this paper we argue that 'ego dissolution' in psychedelic experience is a window on the nature of self-awareness. Ego dissolution provides evidence that the mind uses a predictive coding strategy to represent the self as a unified entity. Under this strategy higher-level models predict that features represented at lower levels are attributes of objects. Thus, for example, in perceptual and sensorimotor feature binding the higher-level modelling of objects is used to integrate representations of features into coherent wholes. We see and feel objects, not concatenations of features, as a result of this top down process. Similarly, we argue, the self is postulated by higher-level processes as an entity to facilitate the binding or integration of information. We argue that this explains a Cartesian intuition that the self is a simple indivisible entity. In psychedelic experience these integrative processes are disrupted leading to the phenomenology of ego dissolution.

We support this idea with evidence from two related sources. The first is research by Sui and Humphreys (2015) on cognitive binding and the role of the self-model in enhancing it. The postulation of a self to which information is relevant makes a difference to the integrity of representations. However the mechanisms involved model that self as a heuristic, a way of making information 'sticky', rather than as a way of tracking the fluctuating cognitive fortunes of an actual entity. Self-awareness is the experience of cognitive processes in which these binding processes are intact.

The second is evidence provided by the phenomenon of 'ego dissolution' reported in psychedelic experience. We argue that that evidence suggests that psychedelics target mechanisms on which self-binding depends. Psychedelic experience degrades these binding processes, enabling us to experience cognition not bound by self-models. We emphasise that the 'self' which dissolves in psychedelic experience is not an actual entity or an object of perception, interoception or introspection but an entity inferred by the mind to predict the flow of experience in and across cognitive modalities. As Thomas Metzinger (2016) put it: "There is just no entity there, no individual substance, and scientifically we can predict and explain everything we want to predict and explain in a much more parsimonious way."

We can contrast Metzinger's view with Hohwy and Michael's (forthcoming) "causal realist interpretation of the reference of intentional terms and of the self" which argues that the causal power exerted by the object(s) of self representation implies a causally efficacious entity underlying the hierarchy of integrative processes. Sui and Humphreys similarly argue that the binding power of self-representation cannot be explained by a self that is essentially a theoretical or narrative abstraction. Ultimately we will argue, on the basis of the psychedelic evidence, that Sui and Humphreys, and Hohwy and Michael, are right to reject a purely narrative view of the underpinnings of self-awareness: the self-model is deeper, more robust, and more cognitively ubiquitous than that. But we will side with Metzinger and against Hohwy and Michael in denying that anything, including the self-model, possesses the right attributes to qualify as a self. The issues are subtle since all sides agree on the integrative role of the self-model and the predictive hierarchical nature of self-modeling. We return to this issue in the final section. At this point we note only that the phenomenology of ego dissolution seems easier to explain if the subject is experiencing the disintegration of a system whose integration she normally experiences in terms of an indivisible mental (but not immaterial) substance.

We offer a diagnosis of this phenomenon in terms of self-binding. We discuss the nature of binding and self-binding, arguing that self-binding does not entail the existence of an object to which attributes are bound (though it does require the *representation* of an object, to which representations of attributes are bound.) We then turn to the main sections of the paper that explain the phenomenon of ego dissolution in psychedelic experience. We describe the phenomenology and neural correlates and show that ego dissolution is best understood as a phenomenon of unbinding. In a final section we situate our account in the conceptual framework of contemporary debates and address some puzzles and remaining issues. In brief our conclusion is that even in florid psychedelic experience the self-model is never entirely destroyed. Rather as the coherence it normally imposes degrades, we become aware that our normal experience of unity depends on a modeling process. Just as disorders of feature binding help disclose the nature of object representation, ego dissolution discloses the nature of self-awareness.

Furthermore our normal experience of unity compels the inference not just that we are a self, but that that self is a Cartesian substance. The self-model is a hypothesis of a unitary and persisting entity - a bare particular - which owns and inhabits the body, which thinks the thoughts, which feels the feelings, and which was present in past experience and will be present in future experience. It turns out that controversy over the neural basis of self awareness turns on whether the mechanisms which produce the experience of self awareness perform their integrative tasks by modeling the self as an simple indivisible substance.

Binding

The notion of binding solves a problem first discussed for visual representation. It arises from evidence that different visual features of objects, such as colour, shape, and motion, are processed in separate areas of visual cortex. These representational elements are combined into coherent, unified percepts by feature binding processes. Evidence for the existence of feature binding mechanisms comes from conditions in which they fail, such as 'illusory conjunctions' of features induced experimentally or resulting from pathology (Burwick 2014). An example might be a subject presented with a green circle and a blue square who misperceives a blue circle and a green square.

Binding can be described and explained at the phenomenal (unity of experience), cognitive (coherence and integration) and neural (mechanism) levels (Revonsuo 1999). There is no single theory of the nature of binding. Some theorists treat it as a global phenomenon involving the integration of information across large-scale networks. Others focus on local or modular integration of percepts or even perceptual elements, proposing that such modular integration is necessary before candidate representations can be globally integrated. However in the absence of a final theory it remains true that cognition and experience require the coherent functioning of spatially and temporally distributed neuronal populations to produce integrated representations.

The resurgence of interest in the phenomenon by neuroscientists in the 1990s produced different theories of binding. It has been explained in terms (i) of phase synchrony (peaks and valleys of waveforms occurring simultaneously) across distributed circuitry (Singer 1999); (ii) convergence zones: specialized circuitry that integrates signals fed forward from lower level systems (Damasio 1989). Such convergence zones could be hierarchically organized, elements of a percept being individually unified then fed forward to higher levels to be integrated into the overall representation of a perceived scene and (iii) integrative properties of layer V pyramidal cells (Bachmann 2015). Refined versions of this idea suggest that information thus bound passes through a processing bottleneck enabling it to become the object of metacognitive processes. (i)-(iii) fit well with attentional and global broadcast theories of consciousness, which make availability to executive processing the essence of consciousness. On these views unbound information cannot be the object of conscious awareness. (iv) is a Hebbian theory that proposes that binding consists in the frontally regulated construction and maintenance of transient activity patterns in frontal-posterior (especially parietal) circuitry, stabilizing and integrating perceptual representations, which then become available to executive functioning (Ballard *et al*. 1983, van Essen *et al*. 1992).

These theories (i)-(iv) can be made consistent. Conscious representation might depend on synchronous firing within convergence zones whose properties are modulated from above according to context.

Here we want to note several aspects of binding theory. It is proposed to explain the unity and stability of conscious experience and it implies a neural mechanism. It explains the unity of conscious experience in terms of functional coupling between cognitive subsystems and there is a strong implication that that such coupling requires frontal involvement. Relatedly, the disruption, alteration or disappearance of consciousness is produced by the disruption of frontal-posterior coupling (Mashour 2013). This last point reminds us that consciousness comes in different forms and that a binding theory of consciousness should help explain (ultimately) sleep, dreaming, coma, alert waking, psychosis, as well as the state we are interested in here, psychedelic experience.

We think that the phenomenon of ego dissolution is a case where understanding the nature of phenomenal unbinding can illuminate the nature of binding: in this case the binding which underlies the phenomenon of self awareness.

Binding and Predictive Processing

When the binding problem and tentative solutions were first proposed the predictive processing theory had not undergone its recent revival but we note that it provides an elegant framework for understanding the binding of information. Predictive processing theories of cognition treat the brain as a neurally instantiated processing hierarchy, with generative models at higher levels predicting bottom-up inputs from lower levels. The discrepancy between predicted and actual input takes the form of an error signal, with the magnitude of error known as 'surprisal'. Error signals are cancelled either by updating the model or by taking action (known as 'active inference') to alter the discrepant input (Hohwy 2013).

This framework provides an elegant solution to the binding problem. Regularities in sensory input over time constrain the combinations of features into objects that will be predictively successful. So the binding of features together into coherent percepts is determined by the probabilistic model which best matches present and past inputs, and the choice of probabilistic model is determined by regularities in the inputs. Binding, on this view, is essentially a kind of top-down abductive inference. If I am fielding in a game of cricket, the patterns in the inputs to my visual system are efficiently and reliably predicted by a model that posits various entities - a batter, a bat, a ball - each possessing various attributes such as colour, shape, location, speed and direction of motion. So object perception is a matter of hypothesizing an ontology that makes the flow of sensory input intelligible and predictable.

Our central idea here is that self-representation can be understood using the predictive framework in the same way as object representation. The self model is an object posited to make sense of, to unify, and to predict ongoing patterns of egocentric, salient, autobiographical experience.

The notion of egocentric experience reflects the fact that experience is spatially and temporally organized from a perspective or location such as point of view or origin of movement. For example sensorimotor control depends on integration of sensory input at a point or points internal to the organism.

Salience refers to that fact that the organism is bombarded by information only a fraction of which is relevant to its goals and interests. Each of those goals, which range from phylogenetically ancient (maintaining homeostasis) to recent (maintaining social reputation) creates a dimension of salience which requires the mind to allocate processing resources adaptively. The ability to represent these multiple dimensions of salience depends on hierarchically organized neural circuitry, which focuses perception and cognition, biasing cognitive systems to the processing of relevant information. This salience network coordinates the interaction of neural systems that detect and evaluate relevance, bias processing accordingly and, importantly, allow us to feel the consequences as affective states.

Thus we are organisms which experience and act in the world from a unique physical (spatiotemporal) and affective orientation. In the process the mind makes models to explain the way the world makes us feel as we move through it. When we deliberate on and communicate the resultant experience we represent the integrated functioning of the egocentric and salience systems as unified through time in a single entity.

In effect the salience system links the egocentric self-models that manage the physical/bodily interface with autobiographical models which situate the organism historically. The salience system tells the organism which information matters and how it matters, moment to moment and through time. In effect the salience system is constantly creating the illusion of substantial selfhood by binding information into a representation not of the world in itself, but the world as it matters to the organism. As Seth (2013) put it:

> emotion and embodied selfhood are grounded in active inference of those signals most likely to be 'me' across interoceptive and exteroceptive domains. In humans, self-related predictive coding simultaneously engages multiple levels of self-representation, including physiological homeostasis, physical bodilyintegrity, morphology and position, and - more speculatively - the metacognitive and narrative 'I'.

The narrative 'I' is Dennett's (1991) narrative self or Damasio's (2010) autobiographical self, which allows us to experience high level (attempted) control of the integrated functioning of the egocentric and salience systems.

We think that Dennett is correct that the narrative self is a model which abstracts from integrated functioning of a hierarchy of egocentric and salience systems to posit a simple unified entity of which those integrated features are attributes. This view is consistent with the idea that as that functioning disintegrates we will no longer feel like unified entities.

The Architecture of Subjectivity

That the salience network is activated in such a variety of conditions, ranging from basic perceptual processing to high-level metacognition, is a consequence of the way minds evolved. The mind did not evolve to range impartially over all the information available in the world and represent its causal and conceptual structure. Rather the mind naturally allocates resources to information relevant to organismic goals and interests, represented at different time scales and levels of explicitness. Simplifying, we can say that emotional processes represent relevance to goals and interests, the salience/reward system focuses attention cognition and behaviour adaptively and affective systems allow us to experience the consequences as felt body states.

A consistent finding in the case of self-referential processing is activity in a network of midline structures whose hubs are involved in emotion, motivation, salience, and the switching of attention between neutral/external and self-relevant information (Qin and Northoff 2011). These structures are not active when attention is focused 'outward'so to speak on the perceptual environment or on problem solving with an impersonal aspect. It seems clear that smooth context-sensitive activity in this midline-centred network is an essential aspect of cognitive function. Organisms need to be able to allocate cognitive resources appropriately according to whether the context requires accurate representation of the world (concrete or abstract) or the significance of the world to their goals and interests.

The cortical midline structures repeatedly implicated in self reference divide into two distinct, large-scale functional networks. The salience network (SLN), which we have been discussing, is centered on key hub regions such as the anterior cingulate cortex (ACC), implicated in error detection and task switching, and the anterior insular cortex (AIC), implicated in interoceptive processing and conscious emotional feelings (Seth *op. cit.*). Meanwhile, the much-discussed default mode network (DMN) is centered on key hub regions such as the medial prefrontal cortex (MPFC), posterior cingulate cortex (PCC), and inferior parietal lobule (IPL; Davey *et al*. 2016).

The DMN was originally identified in neuroimaging studies of the resting brain (Raichle *et al*. 2001). It has since been found to be activated by many self-referential tasks, including 'prospection' or 'mental time travel' - the autobiographical simulation of past and future experience - and theory of mind (Spreng and Grady 2010). Of course, mind-wandering in task free conditions often concerns self-referential themes. The pioneering studies of Damasio, and much subsequent research, support the view that the MPFC is centrally involved in the attribution of personal relevance to (that is to say, the egocentric evaluation of) actual or simulated autobiographical episodes (D'Argembeau 2013). In relation to the different levels of self-modelling, the DMN is implicated in higher-level, narrative self-representation, as opposed to the more minimal embodied form of self-awareness supported by the SLN.

The PCC is a functionally enigmatic region with considerably higher metabolic activity and structural connectivity than most brain areas, leading some to describe it as the "core node of the DMN" (Davey *et al*. 2016, 390). In their analysis aimed at delineating the substrates of self-reference within the DMN, Davey *et al*. found that the optimal model was one in which "self-related processes were driven by PCC activity and moderated by the regulatory influences of MPFC." Activity in the left IPL, which is known to play a role in the retrieval of semantic information, was also part of the core self-reference network identified by this analysis.

Many intriguing findings support a key role for the PCC in self-reference. Neurofeedback studies of meditators suggest that PCC activity co-varies not with mind wandering as such, but with the experience of becoming 'caught up' in a train of thought. Brewer proposes that the PCC is involved in getting 'caught up in experience', whether it be a particularly compelling rumination or a drug craving - and numerous results find meditation downregulating PCC activity (Brewer *et al*. 2013, Brewer and Garrison 2014). Experimental results implicate the PCC in processes such as integrating information about spatial self-location and body ownership (Guterstam *et al*. 2015). According to one recent model, the PCC is a key hub involved in 'tuning' the connectivity of many other brain networks, regulating the balance between internal and external attention, as well as the breadth of attention (Leech and Sharp 2014). These observations about PCC function cohere with findings from psychedelic neuroscience which we will discuss below. First, however, we turn to the generic function of 'self-binding' which seems to be implemented by these self-processing networks.

Self Binding

The concept of self-binding comes from the work of Sui and Humphreys (2015) who proposed it to explain why cognition across domains and levels is enhanced for self-relevant information. Subjects asked to classify words on the basis of self-relatedness or meaning remember more self-related words, and moreover remember more episodic details surrounding the learning of those words, suggesting enhanced mnemonic binding. Meanwhile, in face processing studies, subjects are quicker to recognise their own face than friends' or strangers' faces, whether upright or inverted. Friends' faces also have an advantage over strangers', but only in the upright condition, suggesting that self-reference confers a unique Gestalt or integrative advantage. (Other results militate against an explanation of this effect in terms of mere familiarity).

Sui and Humphreys also cite evidence that self-reference enhances coupling between different temporal stages of information processing, possibly related to temporal binding, and enhances functional coupling between specific brain regions such as the aforementioned DMN, implicated as a neural substrate for autobiographical thought.

Sui and Humphreys also show that there is an attentional and decisionmaking enhancement effect for self-related information which speeds up sequential processing by enhancing "binding between different states of processing" (*ibid*., 724). They noted that these effects could best be explained in terms of an integrative role for self-related processing and hence they employed the concept of self-binding. Given the necessity for binding in establishing coherence they then examined a role for functional coupling of distributed circuitry consistently implicated in self-referential effects. Dynamic causal modelling of fMRI data showed "self-reference enhances the neural coupling between regions concerned with a core self-representation (vmPFC) and with distinct domain-specific regions associated with different components of the self, including self-related attention (LpSTS)" (*ibid.*, 724). Metanalyses of fMRI data reinforced the finding that "there is enhanced neural coupling for self-processing (vs other-related processing) between the vmPFC/pregenual anterior cingulate (pACC) and several other regions including the bilateral anterior insula, left striatum, right thalamus, and amygdala" (*ibid.*, 724).

Further evidence that self-relevance enhances processing comes from the role of affect in perceptual binding. It is well-established that perceived objects evoke immediate affective responses. Lebrecht *et al*. (2012) found that even paradigmatically neutral objects such as coffee cups and clocks evoke measurable 'micro-valences', concluding that "valence should be construed as a property of object representations" - that is, the affective response is bound to the percept, forming a unified representation, rather than being merely associated with it. The view that affect is bound to perception is supported by studies showing the role of the amygdala in driving eye saccades in face perception, directing the gaze to emotionally salient stimuli.

At higher levels affect is bound to memories and imaginative states invoked in reverie or deliberation, a process which seems to depend particularly on the vmPFC. This suggests that the vmPFC is recapitulating at a higher level the role played by the amygdala in perceptual processing. Namely co-ordinating the construction of self-relevant representations. One nice demonstration of this phenomenon arises in a distinction drawn between episodic (the episodic representation of previously acquired information) and autobiographical memory (in which the subject feels herself present as part of the recollected experience) by Asaf Gilboa:

> the Ventromedial PFC ... does so by establishing a *self-related* retrieval template that sets up the parameters against which retrieved memories are evaluated based on (or which give rise to) a general intuitive 'feeling of rightness'. Thus, the monitoring of the veracity and perhaps cohesiveness of autobiographical memories is primarily mediated by the ventromedial PFC. (2004; our italics).

For Sui and Humphreys the self plays far too important a role to be dismissed as a narrative fiction. They frame their argument in terms of the *function* of self-reference and argue that the integrative function they identify could not be performed by a fiction. They describe different elements of a self-referential processing system as constituting an "integrative hub for information processing" (Sui and Humphreys *op. cit.*, p. 719). The key nodes of the network they identify are those implicated in emotional binding and affective experience, the enhancement of attention for emotionally salient and motivating information and the switching of attention according to context.

These systems together perform the function identified by Sui and Humphreys. At perceptual and sensory levels they ensure that salient information is preferentially attended to and integrated into coherent percepts. At higher, conceptual or metacognitive levels they ensure that the same is true of the representations that figure in memories, stories, and causal explanations. In a review of the neural correlates of self-binding, which are the substrates of the network we outline above Lou *et al*. concluded "self-awareness is an integral function of all conscious experiences, binding conscious experiences together into a single construct with a sense of unity of consciousness" (in press).

This is a very strong claim. It implies that conscious experience would not arise in the absence of self-binding. The work of Sui and Humphreys suggests that this is not the case. Their subjects did not lose consciousness when perceiving self irrelevant information. The same is true for patients with lesions to components of this network. However such patients do seem to have compromised abilities in tasks (such as autobiographical simulation, personal decision making and social interaction) that we pretheoretically describe as requiring self-awareness. As we will show, the neuroscience and phenomenology of psychedelic ego dissolution put further pressure on the view that self-binding is necessary for consciousness. Indeed, psychedelic consciousness, in which the mechanisms of self-binding are compromised, is usually described as a state of increased or intensified consciousness, leading Carhart-Harris *et al*. (2014) to suggest that self-referential processes constrain consciousness rather than enabling it.

Recognizing the role of self-binding and self-models leaves questions about the mechanisms of binding unanswered. As we noted earlier many candidates have been proposed, including various forms of temporal correlation (synchronisation of cells or functional coupling of brain regions; Singer 1999), convergence of modular input streams in high-level integrative brain regions (Damasio 1989), and even intracellular processes implemented in cortical pyramidal cells (Bachmann 2015).

At this point evidence about the actions of psychedelic drugs and the experience of ego dissolution becomes relevant. Under the influence of psychedelics we continue to represent the world and our bodies but attention is captured and allocated in different ways, experience seems both more intense and less personal, and salience, affective feeling and motivation become detached from personal goals and history.

Psychedelic Ego Dissolution

'Classic' (serotonin 2a receptor agonist) psychedelics such as mescaline, psilocybin, and dimethyltryptamine (DMT, a key constituent in the South American beverage ayahuasca) have a long history of religious, spiritual, and medicinal use in various cultures (Sessa 2012). Serious scientific interest in these substances was sparked by the accidental discovery in the 1940s of the extremely potent psychoactive effects of lysergic acid diethylamide (LSD). During the 1950s and 60s, psychedelics were studied intensively as models of psychotic and mystical states, as psychotherapeutic agents, and as instruments for mapping the varieties of human consciousness (Osmond 1957). However, uncontrolled use of the drugs in the context of the hippie counterculture led to socio-political controversy, culminating in the virtual cessation of human psychedelic research for some decades.

Since the early 1990s this research has been slowly but steadily resuming, with greater methodological rigour and aided by the many new technical and theoretical innovations in the mind and brain sciences. Several small studies have revealed preliminary evidence for the safety and therapeutic efficacy of carefully controlled psychedelic administration (dos Santos *et al*. 2016a, Griffiths *et al*. 2016, Ross *et al*. 2016). Meanwhile, neuroimaging investigations have begun to identify neural correlates of the changes in cognition and consciousness caused by psychedelics (dos Santos *et al*. 2016b).

The remarkable variability and alleged ineffability of psychedelic experiences pose barriers to describing these states. But some progress has been made on charting the phenomenology of the 'antipodes of the mind' (Huxley 1954, Masters and Houston 1966, Shanon 2002). Psychedelics alter many aspects of experience: sense perception, emotion, cognition, and the apprehension of time and space. But of all their effects, perhaps none is more provocative than the profound alteration to the ordinary sense of self or ego known as 'ego dissolution'. The countercultural icon Alan Watts, responsible for popularising both Eastern religion and psychedelics in the 1960s, wrote: "there are certain types of change which are usual enough to be considered characteristic of psychedelics: the sense of slowed or arrested time, and the alteration of "ego boundary" - that is, of the sensation of one's own identity" (Watts 1964). Psychedelic subjects often report that their sense of being a self, or 'I', distinct from the rest of the world 'out there', is weakened, altered, or abolished during the intoxication.

Ego dissolution experiences often occur in the context of mystical states in which the ordinary sense of self is replaced by a sense of union with an ultimate reality underlying all of manifest existence - the famous 'cosmic consciousness' experience. Shanon describes the content of this apparent metaphysical realisation as "idealistic monism with pantheistic overtones" (2002, 163). The propensity of psychedelics to occasion such experiences goes some way to explaining their history of religious use. Indeed, intellectuals such as Watts and Aldous Huxley were initially drawn to psychedelics due to their prior interest in mysticism. With respect to ego dissolution, it is worth noting that apprehending the non-existence of the individual self is a central goal of Buddhist meditation (Albahari 2014). There is evidence that mystical states are important for the therapeutic effects of psychedelics (Garcia-Romeu *et al*. 2016) so explaining the ego dissolution experience is a crucial step in theorising the mechanisms of psychedelic treatment.

Early theoretical speculations about psychedelic ego dissolution strikingly anticipated the key ideas we will develop in the rest of the paper. In accordance with the dominant orientation of mid-20th century psychiatry, Freudian constructs were used liberally - some of which have recently been revived and linked to the predictive coding framework in the context of the 'neuropsychoanalysis' movement (Carhart-Harris and Friston 2010). However, Freudian commitments are inessential to the central points here. Savage (1955) and Klee (1963) both suggest explanations of ego dissolution in terms of failures of mechanisms of cognitive integration, and view these compromised perceptual (particularly interoceptive) integrative mechanisms as the basis of the self-model: "Lacking a reliable inflow (or integration) of stimuli, particularly from his body, the subject has lost much of the basis for his self-percept" (Klee 1963, 465). Both authors also liberally refer to the breakdown of cognitive processes of expectation (cf. prediction) in explaining psychedelic ego dissolution. These early speculations sit very comfortably with currently influential theoretical frameworks in cognitive neuroscience, and suggest a bidirectional, mutually reinforcing relationship between self-representation and cognitive integration.

Another important point is that ego dissolution is not an all-or-nothing affair. Different aspects of self-awareness may be more or less disrupted in different ways on psychedelics. Various authors have suggested that some vestiges of self-awareness are preserved in most, if not all, psychedelic experiences (Pahnke 1969, Shanon 2002), which helps explain the puzzling fact that autobiographical memories can apparently be formed of these putatively selfless episodes (Metzinger 2005). Moreover, there are aspects of psychedelic phenomenology which may not be explicitly described as ego dissolution but are still readily explained by our account. Subjects often find their attention drawn to stimuli which they normally would not notice; as Watts puts it, psychedelics "make the spotlight of consciousness a floodlight which... brings to light unsuspected details - details normally ignored because of their lack of significance" (Watts 1964). Attention is no longer guided exclusively by adaptive and egocentric goals and agendas; salience attribution is no longer bound to personal concern.

Subjects often become less defensive and better able to view their own thoughts and feelings dispassionately - one main rationale for early therapeutic use of these drugs (Eisner and Cohen 1958). A very common experience is to see one's own dysfunctional emotional or behavioural patterns, and the possibility of alternatives, with striking clarity (Shanon 2002, 162-163). There is a tendency toward decentring and the objectification of self-related phenomena which ordinarily are taken very personally and evoke strong emotional reactivity (Soler *et al*. 2016). All of this suggests that, even when ego is not felt to dissolve altogether, the contents of consciousness are less filtered through considerations of self-relevance than is usual. Various cognitive processes which are usually tightly coupled to self-representation become decoupled from it.

Ego Dissolution as Unbinding

When Carhart-Harris *et al*. (2012) published the first human fMRI studies of serotonergic psychedelics their results caused quite a stir. Not only did they find that intravenous psilocybin caused an overall reduction in neural activity (measured by BOLD signal), apparently contradicting earlier PET studies showing metabolic hyperactivity on psilocybin (Vollenweider *et al*. 1997). The decreases were concentrated mainly in the DMN. Psilocybin decreased activity in DMN regions but also the integrity of the network as measured by functional connectivity analyses. The normal functional coupling between key DMN hubs diminished - in particular, between the MPFC and the PCC. Despite apparent inconsistency with PET results, the fMRI results cohered with MEG investigations in the same study. These electrophysiological measures revealed another striking result: decreased alpha power (which has been linked to inhibitory processes) in the PCC correlated with psychometric ratings of ego dissolution.

Not all of these findings have been replicated in all subsequent psychedelic fMRI studies. But various observations support a role for downregulation of the DMN, and the PCC in particular, in psychedelic ego dissolution. Palhano-Fontes *et al*. reported decreased BOLD signal in DMN nodes including the MPFC and PCC during ayahuasca intoxication (Palhano-Fontes *et al*. 2015). Meanwhile, thinning of the PCC has been observed in long-term ayahuasca users, with the degree of thinning correlated with both psychometric scores for 'self-transcendence' and the extent of prior ayahuasca use (Bouso *et al*. 2015). Interestingly, these ayahuasca users equaled or outperformed matched controls on tests of neuropsychological function, suggesting that this PCC thinning is not linked to cognitive impairment. The connection with findings about PCC deactivation in 'effortless awareness' meditation is obvious, and bolstered by the finding that acute ayahuasca intoxication increases mindfulness-related capacities (Soler *et al*. 2016).

Matters have been complicated by recent apparently conflicting findings concerning the neural correlates of ego dissolution. Lebedev *et al*. (2015) reported that disintegration not of the DMN but of the SLN correlated with psilocybin-induced ego dissolution. Referring to the apparent conflict with prior results, Lebedev *et al*. note that while the DMN is frequently linked to the narrative self, the salience network has been linked with a more minimal or embodied sense of self. The distinction between narrative and minimal selfhood is commonplace in recent literature and will form part of our explanation of this pattern of results too.

Lebedev *et al*. also found ego dissolution significantly correlated with reductions in interhemispheric connectivity and in functional coupling between the medial temporal lobes (MTL) and cortical regions. This connects with earlier findings of MTL-DMN decoupling under psilocybin (Carhart-Harris *et al*. 2014) - though in the earlier studies, this decoupling did not significantly predict ego dissolution, while in the Lebedev *et al*. study, the MTL decoupled from broader cortical regions than just the DMN.

Most recently, Tagliazucchi *et al*. (2016) found that ego dissolution induced by LSD correlated with increased global functional connectivity, with these increases resulting from a breakdown in the integrity of resting-state networks. Here the DMN and SLN were both affected. The strongest specific correlation with ego dissolution was decoupling of the parahippocampal cortex, in the MTL, from the precuneus - a key DMN node anatomically adjacent to the PCC. In this study disintegration of the DMN also tracked reduced mental time travel to the past, consistent with this network's hypothesized role in this process (Speth *et al*. 2016).

What are we to make of these varied results? The major networks whose breakdown is linked to psychedelic ego dissolution have all independently been linked to one aspect or another of self-representation. Lebedev *et al*. suggest a need for fine-grained psychometric instruments capable of distinguishing between alterations to different aspects of self-awareness. Unfortunately, the ego dissolution inventory recently introduced and validated by Nour *et al*. (2016) does not make such discriminations, so for now we are stuck with theoretical speculation. However, our account will predict that Lebedev *et al*. are correct: different aspects or levels of the self-model are disrupted by psychedelics in different conditions, compromising the integrity of distinct self-binding processes.

We submit that an elegant resolution of these issues is as follows. Sui and Humphreys are correct that the self is more than a mere narrative posit. There is a robust self-representation implemented in cortical midline nodes of the DMN and SLN which plays a causal role in processing at all levels, both enabling and emerging from cognitive binding processes. This model includes both the "pre-reflective experience of "I" as a continuously existing being" (White 2015) as well as the various perceptual, embodied, and narrative representations of attributes, goals, and events which are bound to that being. The plastering of these representations with "sticky 'I, me, mine' labels that... prove painful to remove" (Kingsland 2016, 285) explains the anxiety and dysphoria which sometimes attend ego dissolution experiences (albeit relatively rarely in controlled settings.) The multi-layered nature of the self-model explains the apparently variable neural correlates of the same coarse-grained subjective report of "ego dissolution". Savage suggests that on LSD "[changes] in body ego feeling usually precede changes in mental ego feeling and sometimes are the only changes" (1955, 11), evincing an early clinical recognition that different aspects of the self-model might be affected to varying extents by psychedelics.

However, it does not follow from the existence of a robust, causally efficacious, and multi-layered self-model that the entity represented by this model exists. We agree with Metzinger that it does not, and reject Dennett's identification of the self with narrative self-models as well as Hohwy and Michael's identification of the self with hierarchical predictive self-models. This is because the self-model does not posit the existence of a narrative or a model; it posits the existence of a substance, a prime mover, a persistent entity that underlies, owns, and initiates thoughts, experiences, and actions. In accordance with predictive coding principles of cognitive efficiency, the postulation of a bare particular to which events and attributes are bound is an economical means to prediction and explanation of the flow of information.

Hohwy and Michael (forthcoming) argue that the self-model qualifies as a self because it performs many of the functions attributed to the self, such as being a "hidden cause" of thought, emotion, and behaviour. It is true that the self-model does these things. But on our view it is more like an existential placebo than a successfully self-referential model. The expectation that a drug treatment will work is a mental representation which is capable of performing some of the functional role which it attributes to its hypothesized object - viz., the pharmacological capacities of a chemical. But this does not mean such an expectation is a pharmacological capacity of a chemical. It does some of the right stuff, but it is the wrong kind of thing.

Analogously, consider a theist who mentally represents God as the source of meaning and purpose in her life. Plausibly her mental model of God as an objectively existing and meaning-providing entity will cause her to have experiences of meaning and purpose in life - that is, it will perform some of the functional role that it attributes to its hypothesized entity. But this does not mean the theist's God-model qualifies as God. Again, it does some of the right stuff, but it is the wrong kind of thing. It is not a transcendent deity; it is a system of mental representations in someone's head. One way of putting the point, then, is that the concept SELF is not purely functionally defined but has crucial *substantial* metaphysical commitments; playing part of the functional role of a self is an insufficient qualification for selfhood.

Our argument, then, turns crucially on the claim that the content of the self-model is that of an enduring substance which is distinct from all the mental, emotional, and physical activity of which it is supposed to be the owner. As Metzinger (2003) points out, our 'phenomenal avatar' (conscious self-model) is *transparent*: one does not feel like an avatar encoded in a "biological data format", one feels like a unitary, persisting substance or entity. The prevalence of this Cartesian intuition in philosophical discussions of selfhood (as exhibited by standard responses to Parfit's famous teleportation thought experiments) supports this psychosemantic claim. Some may find this claim introspectively dubitable. But it is precisely the ubiquity of this sense of 'I' that makes it difficult to isolate phenomenologically - and this is the reason why phenomena such as ego dissolution are theoretically valuable. As Savage says in his discussion of LSD phenomenology, "By and large the individual is not aware of the ego boundaries of his mind and body and becomes aware of them only when a change has occurred in them" (1955, 6). Psychedelics, by deconstructing the avatar, render it opaque and acquaint subjects directly with its representational nature. The transformative existential shock which often attends this discovery testifies to the fact that a mere avatar is not what we, in the ordinary and sober course of things, deeply feel and take ourselves to be.

Conclusion

Dennett (1992) famously argued that the self is a 'centre of narrative gravity' akin to the centre of gravity of an object: an abstraction, but no less real or predictively useful for that. On the predictive coding construal of the integrative self, the self-*model* functions as a centre of *representational* gravity - not just in narrative processes but also in lower-level affective, bodily, and spatial processes. It is a representation of the 'point' around which everything else revolves. But crucially, it is not a representation as of a mere point, but as of a particular. This is why we reject Dennett's metaphysics of selfhood, as well as Hohwy and Michael's claim that the self-model has enough of the right attributes to qualify as a self.

If our conjectures are right, the content of the self-model is Cartesian: it is of a substance or an entity which *has* the properties and experiences. And here we agree with Metzinger (2016) that there "is just no entity there, no individual substance, and scientifically we can predict and explain everything we want to predict and explain in a much more parsimonious way." Thus, our view is structurally analogous to Mackie's (1977) error theory of morality, conjoining the psychosemantic claim that the self-representation is as of a Cartesian substance with the ontological claim that no such substance exists. It is also substantially similar to Metzinger's views about the self-model, developed in the context of a specific case and a mechanistic proposal (self-binding on predictive processing principles) about how the model performs its adaptive functions for the organism.

All of this fits smoothly with the idea that the DMN and SLN implement narrative and embodied aspects of self-representation respectively. The self-representation as we conceive it serves as an organising principle at different levels and in different domains of processing. Perceptual representations are organised in an egocentric space; interoceptive representations are interpreted as signals of adaptively relevant events or 'core relational themes' (Prinz 2004); and narratives are structured around the fortunes and prospects of a protagonist. At all levels, salience is attributed, attention directed, and information integrated in accordance with the relevance of information to the organism's goals. As James Kingsland (2016, 209) puts it, "we have evolved into an ape that takes things personally".

Conclusion

In this final section, I summarise the arguments given in the four papers, and suggest directions for future research. The arguments given have made significant inroads into the philosophical analysis of psychedelic phenomena, but many unanswered questions remain, most of which will benefit from further results of the ongoing scientific study of psychedelics and their transformative effects.

Summary of Arguments

Overall, I have argued that the 'entheogenic conception' of psychedelics as effective agents of knowledge gain and spiritual growth is both consistent with naturalism and plausible in light of current scientific knowledge.

In the first paper, after arguing for the importance of a naturalistic approach and reviewing the history and transformative effects of psychedelics, I used Craver's account of causal relevance to argue that four lines of evidence implicate the psychedelic ASC in the transformative process: the apparently epistemic phenomenology of psychedelic transformation, the analogy with non-drug-induced transformative experiences, the correlations between phenomenal variables and psychological benefit variables, and the 'de-rigidifying' theory of psychedelic therapy. From the causal relevance of the ASC I concluded that psychedelic transformation is a distinctively 'humanistic', that is meaning-involving, psychopharmacological intervention. I then suggested three kinds of epistemic benefits that plausibly result from psychedelic transformation. These were: knowledge by acquaintance of the mind's potential, suggested by the de-rigidifying theory of psychedelic therapy; knowledge by acquaintance with the metaphysical nature of the (sense of) self, suggested by the phenomenon of ego dissolution; and revitalized capacities for the acquisition of modal knowledge, suggested by claims of increased cognitive flexibility following psychedelic ingestion (and again, bolstered by the de-rigidifying theory.)

In the second paper, after once again reviewing the history and science, I used Bortolotti's notion of epistemic innocence to argue that psychedelic states sometimes have the potential to cause significant and otherwise unavailable epistemic benefits to subjects. These epistemic benefits include the three kinds argued for in the first paper, plus indirect epistemic benefits consequent on psychological benefits. By freeing subjects from debilitating forms of psychological distress, and increasing their Openness to Experience, psychedelics plausibly result in a more pro-epistemic behavioural profile characterised by increased curiosity, positive mood, and engagement with the world. I suggested that the epistemic innocence of psychedelic states is highly relevant to policy debates because, even if they are not the only thing that matters, truth and knowledge do matter; the concern that psychedelic therapy may be "foisting a comforting delusion on the sick and dying" is real and legitimate. I also argued that the analysis of psychedelic states reveals an ambiguity in the formal definition of epistemic innocence; namely, it is not clear whether what is required for epistemic innocence is the unavailability at-a-time of alternative cognitive processes leading to equivalent epistemic benefits, or of the beneficial epistemic *results* of those processes. I suggested that the distinction between these two possibilities ought to be borne in mind in future research into the complex epistemic profiles of intuitively 'imperfect' cognitions.

In the third paper, I explored the potential of psychedelic experiences to alleviate the 'neuroexistentialist' anxiety consequent on the disenchantment of the world, arguing that their capacity to alleviate other kinds of existential distress provides a prima facie case for investigating this potential. I noted the problem arising from the apparent centrality of non-naturalistic metaphysical apprehensions to psychedelic transformation. I then used current theoretical knowledge about the mechanisms of psychedelic transformation, and phenomenological reports of psychedelic subjects, to argue that such metaphysical apprehensions are far from the whole story. I proposed that there are central means whereby psychedelics can combat existential distress that are naturalistically acceptable; namely, disruption to processes of self-representation, leading to a de-coupling of attention from personal concerns and the consequent availability of broader perspectives, leading to wonder and appreciation for life and a diminution of excessive and distressing focus on the existential plight of the vulnerable individual self. I also suggested that such neurophilosophical investigations of psychedelic-induced re-enchantment can make a valuable contribution to the related philosophical projects of naturalistic eudaimonics and naturalizing spirituality, which collectively constitute a promising and distinctive kind of response to neuroexistential anxiety. I pointed out that the central means of psychedelic re-enchantment which I identified are common themes in philosophical accounts of naturalistic spirituality

In the fourth and final paper, Philip Gerrans and I argued that psychedelic ego dissolution can best be explained as the result of a neuropharmacological disruption to 'self-binding' processes implemented in accordance with predictive coding principles. We suggested that hierarchical predictive models unify and integrate information in various domains and at various levels of processing by positing a discrete and unitary entity - a 'bare particular' or Cartesian substance - to which representations of attributes are bound. The psychosemantic claim that we represent ourselves as such a particular explains both prevalent Cartesian intuitions in philosophical discussions of self-awareness as well as the transformative existential shock that attends the psychedelic-induced realization that no such particular in fact exists. On the basis of this theoretical account we sided with Metzinger and against other theorists such as Hohwy and Michael in arguing that the neurocognitive nature of self-awareness and alterations thereto support an error theory of self-representation; even if predictive models themselves perform some of the functional role attributed to the entity which they posit, they do not have the right attributes to qualify as a self, because the self-model posits a unitary, persistent and indivisible entity. Self-models play some of the roles that a self would play, but they are the wrong kind of thing. This theory of ego dissolution contributes to naturalizing the entheogenic conception by showing that psychedelic experiences can afford subjects veridical and transformative insights into the very nature of their own existence.

Directions for Future Research

Several questions in the philosophy of psychedelic transformation remain to be addressed, either at all or in more detail. For instance, in the first paper, I gave reasons for thinking that epistemic gains such as knowledge by acquaintance with the potential of the mind and with the constructed nature of the sense of self are causally involved in the psychedelic transformative process. But more work needs to be done to show precisely how such epistemological concepts map onto specific components of the transformative mechanism.

This is an area where the ideas from philosophy of science about causal relevance and multi-level explanation, briefly touched on in the first paper, could be extremely helpful. Theoretical investigation into psychedelic transformation has continued to emphasise a common mechanism operating across different conditions: downregulating connector hubs, thereby rendering the brain more flexible and allowing the potentiation of more adaptive pathways. As I argued in the first paper, certain considerations from the philosophy of science suggest that a purely dynamical interpretation of this theory needs to be supplemented with mechanistic details to be genuinely explanatory. So far, so good. But it is still an open question whether those mechanistic details need refer to specific (kinds of) representational contents.

Nichols *et al*. (forthcoming) emphasise changes to whole brain dynamics, as mechanistically realized in changing connectivity between hub regions and other networks, as a common mechanism in different cases of psychedelic transformation. They suggest that the mystical experience might simply be an epiphenomenon of this transformative mechanism, rather than causally involved itself. Perhaps knowledge by acquaintance with the mind's potential is still plausibly part of the mechanism even on a reasonably content-independent story such as this. But clearly these questions need further analysis and (like most of the unanswered questions I will mention) will become even more tractable in light of further developments in psychedelic science.

Meanwhile, the notion of epistemic risk discussed in the second paper could be developed further, both in relation to psychedelics and other cognitive conditions with mixed epistemic profiles. The idea of assessing a pharmacological or other intervention in terms of its physiological, psychological, or social risk/benefit ratio is familiar enough, but if my arguments in this paper are sound, then epistemic risk/benefit ratios may constitute an important and relatively understudied dimension of an overall risk/benefit analysis of psychiatric treatment modalities. Biddle (2016) suggests that the notion of epistemic risk can help illuminate issues in philosophy of science relating to theory confirmation. It would be an interesting project to see if the idea as he develops it could help in further analysis of the risks involved in voluntarily entering epistemically complex cognitive conditions such as the psychedelic state.

It should be noted that empirical data are clearly relevant to epistemic risk assessment too. I have cited the case of Benny Shanon as showing that the epistemic risk of psychedelics from a naturalistic perspective is not absolute - it is possible to undergo psychedelic mystical experiences while subsequently retaining a critical attitude toward the apparent metaphysical apprehensions occurring therein. But it would be good to have some rigorous data on the likelihood of doing this. If it is genuinely a concern that psychedelic therapy might be "foisting a comforting delusion on the sick and dying" - and I have argued that it is - then it would seem important to conduct quantitative research into the frequency with which psychedelic treatment results in patients acquiring new beliefs which must be regarded as delusive from a naturalistic perspective, and also into the relevance or otherwise of such doxastic changes to clinical outcomes.

Such research could also help make more progress on issues concerning naturalizing psychedelic spirituality, discussed in the third paper. In that paper I argued that mystical metaphysical apprehensions are not the whole story, and that key elements of the psychedelic transformative process are both independent of such apprehensions and consistent with a commitment to naturalism. I think the evidence which I synthesized provides a strong theoretical case for this claim, but it ought to be subjected to direct empirical scrutiny. Quantitative studies into the relationships, if any, between psychedelic-induced metaphysical conversions and psychological benefits could give us much greater confidence regarding the respects in which and extents to which psychedelic transformation is a matter of metaphysical consolation or, alternatively, of naturalistic spiritual transformation. Such research might also be able to support or undermine the suggestion made by Nichols *et al*. (forthcoming) that the psychedelic mystical experience is essentially an epiphenomenon of the dismantling of rigid connectivity patterns by downregulation of connector hubs.

My proposal in the third paper that psychedelics can help overcome existential anxiety in non-patient populations merits empirical scrutiny too. There is certainly extensive anecdotal evidence that healthy subjects can experience a renewed sense of optimism and meaning in life as a result of psychedelic use (Masters and Houston 1966, Shanon 2002). But it would be an interesting project to rigorously and quantitatively examine psychedelics' capacity to combat disenchantment and nihilism in ostensibly mentally healthy people who nonetheless report significant levels of existential distress. This could be combined with the research questions suggested in the preceding paragraphs, to yield a project examining the ability of psychedelics to alleviate existential distress in non-patient populations and the role of metaphysical consolation in their ability (if such they have) to do so. Such research would amount to an interesting kind of experimental philosophy focused on what Langlitz (2016) calls "live philosophical questions".

Further research is also needed on the predictive coding-inspired unbinding theory of ego dissolution developed in the fourth paper. Gerrans and I argue that disruption to different large-scale brain networks in different conditions would result in phenomenologically distinct ego dissolution experiences by disrupting different aspects of the self-model. As we remark in the paper, more fine-grained psychometric instruments capable of discriminating between different varieties or aspects of ego dissolution would help in testing this prediction (although some progress could be made by examining the written or verbal descriptions of subjects in different neuroimaging studies identifying different neural correlates of ego dissolution.) The development of such instruments could be an interesting interdisciplinary project because it ideally ought to draw on descriptions of ego dissolution experiences as well as on recent research, both scientific and philosophical, on the different varieties and aspects of self-awareness.

There are also outstanding questions concerning the potential epistemic benefits of psychedelics which I have not addressed in any of these papers. As I mentioned in the introduction, both Metzinger (2003) and Shanon (2010) endorse the venerable claim that psychedelics can allow subjects to gain therapeutically valuable insights into their own psychology. The account of ego dissolution as unbinding goes some way to establishing a mechanistically plausible explanation of how this could work: by disrupting self-binding processes, psychedelics decouple salience and attention from self-representation, allowing the sort of decentring and objectivity which permits uncomfortable mental contents to be viewed with detachment, honesty and clarity, rather than denial. But much more work needs to be done to develop this proposal, including answering Roche's (2010) arguments against the possibility of any kind of drug-induced propositional knowledge.

Further questions in psychedelic epistemology have more strongly conceptual dimensions. Shanon (2010) lists a variety of other putatively epistemic benefits of psychedelics, including the apprehension or appreciation of truths about nature in new and deeper ways; increases to well-being and stamina; more harmonious social interaction; novel solutions to problems in one's field of specialisation; and enhanced abilities of artistic performance and creativity. Determining whether psychedelics do in fact cause each of these results is an empirical matter, and determining the extent to which each of them amounts to a genuinely epistemic benefit demands rigorous conceptual analysis. Although he does not explicitly use an epistemic vocabulary, similar points apply to Tupper's (2002, 2003) proposals that psychedelics can provide access to mythic and somatic forms of understanding and can enhance existential intelligence.

Another epistemological concept which may be useful in analysing psychedelic transformation is that of 'knowledge how' (Fantl 2016). I have not explicitly mentioned this possibility so far, but some of Shanon's and Tupper's proposals, plus the connections between psychedelics and meditation, raise the question whether certain aspects of psychedelic-assisted learning might best be conceived of as the acquisition of cognitive, emotional, or attentional skills or abilities.

In sum, many more questions remain than I have even attempted to answer here, and most of them require further empirical, theoretical, and conceptual work. With any luck, the psychedelic renaissance, and the philosophical exploration thereof, is only just beginning.

Abstract

Psilocybin as a novel treatment for depression is garnering a lot of attention from both the mainstream media and the academic community. Although phase 3 trials are only just beginning, we feel that it is important for clinicians to consider what psilocybin-assisted psychotherapy might look like in the clinical setting. In this narrative review article we have considered the difficulties that may arise as psilocybin emerges from the research setting, which may hamper its progress towards becoming a licenced medication. Psilocybin has its own unique challenges: the expectation patients come to dosing with having read overwhelmingly positive media; patient suggestibility under the influence of psilocybin and requirement for specialised therapists to name a few. We have also made some recommendations for measures that should be taken in both the phase 3 trials and with clinicians to try and minimise some of the issues raised. In doing so our hope is that psilocybin will continue towards becoming a licenced medication that suitable patients are able to access with relative ease. Practicing psychiatrists need to have an awareness of the potential pitfalls of psilocybin as they will be responsible for prescribing it in the future.

Keywords: psychedelics, psilocybin, affective disorders, review, novel psychoactive drugs

Introduction

Psychedelics,[1,2] particularly psilocybin,[3] are increasingly being evaluated in clinical trials. This article examines the practical considerations required for them to progress from substances mainly used for ceremonial, recreational, and other non-clinical purposes, to routine clinical practice.

History

Psilocybin containing mushrooms were used ceremonially in 16th century Mexico prior to Spanish prohibition. There are some indications that use extended far earlier than this; stone sculptures of mushrooms capped with faces of Gods or animal-like demons were found in El Salvador, Guatemala, and Mexico, the oldest of which dates back to before 500 B.C.[4,5] Despite this long history of use, psilocybin mushrooms were only popularised in Western culture in the 1950s through the article 'Seeking the magic mushroom', written by mycologist Gordon Wasson and published in Life magazine.[6] He was inspired to write the article after being introduced to the ritualistic use in Mexico, where he ingested psychoactive mushrooms in a group session and emerged 'awestruck' from the experience.[6]

Mechanism of action

Serotonergic effects

Psilocybin belongs to the tryptamine/indolamine class of psychedelics.[7] Its metabolite psilocin is the main psychoactive compound found in psychedelic mushrooms of the psilocybe genus. Once consumed orally psilocybin is quickly dephosphorylated into psilocin which has been shown to bind to 5-HT_{1A}, 5-HT_{1B}, 5-HT_{1D}, 5-HT_{2A}, 5-HT_{2B}, 5-HT_{2C}, 5-HT_5, 5-HT_6, and 5-HT_7 receptors.[8] However, it appears that the psychedelic effects of psilocin are largely mediated by just one 5-HT receptor: 5HT_{2A}.[9] Blocking the 5-HT_{2A} receptor with the antagonist ketanserin attenuates the psychedelic effects significantly.[10] In addition, psilocybin's effects in humans have been shown to correlate with 5HT_{2A} receptor occupancy measured by positron emission tomography in the prefrontal cortex and other regions.[11]

Connectivity

Functional MRI of resting state connectivity shows that psilocybin induces changes in global brain connectivity, namely a synchronisation (hyperconnectivity) of sensory networks and a disintegration (hypoconnectivity) in subcortical and bilateral cortical areas comprising associative networks (e.g. the medial and lateral prefrontal cortex, the cingulum, insula, and temporoparietal junction),[8] adding to the evidence that psilocybin disrupts the normal associative mechanisms of the brain's connector hubs.[12] Evidence has also shown that there are changes to network-level functioning i.e. increased cortical entropy (where entropy is defined as a quantity that measures uncertainty, with increasing entropy being synonymous with an increase in disorder within a system), disintegration of networks, and improved communication between brain regions that are normally segregated.[13] These connectivity changes may underlie the demonstration that ingestion of psilocybin or psilocybin containing mushrooms triggers a profound change in consciousness, leading to changes in cognition, emotion, perception, and sense of self that can lead onto a flurry of effects including visual illusions, distorted perception of time, depersonalisation and mystical-type experiences.[14]

The Bayesian model

One hypothesised mechanism of action of psilocybin and other classical psychedelics could be described using a predictive processing model. Broadly, this model ascribes predictive properties to the brain, where it is not viewed as a passive organ in receipt of information, but an active generative organ which encodes prior beliefs about sensory input and their causes, and generates predictions accordingly. Sensory information which conflicts with these predictions must therefore cause the brain to revise its model of the world, or to attenuate the salience given to the input signal in order to preserve its model of the world.[15] The direction of flow of information-whether the model is updated with bottom up sensory information, or the sensory information is attenuated via top down control-is believed to be dependent on the weighting given to the signals.[16] Using this model, psychopathology may be caused by an overly rigid predictive model, where more weighting is given to top down predictions than bottom up information flow, thereby attenuating all information contradicting this model. For example, it has been argued that people with MDD frequently anticipate negative events, where negative predictions continue to shape perspective[17] regardless of the sensory information received. In their comprehensive paper 'REBUS and the Anarchic Brain: Towards a Unified Model of the Brain Action of Psychedelics', -where rebus is an acronym for relaxed beliefs under psychedelics- the authors argue that psychedelics may help reduce the impact of prior beliefs on immediate perception by relaxing the weighting of pathologically over-weighted priors (or schema) underpinning various expressions of mental illness, thereby increasing sensitisation to bottom up information, and reducing top down control.[16] Consequently, this may create a window where these beliefs can be challenged and re-examined.

Psychological flexibility

Psychological flexibility is defined as the ability to stay in contact with the present moment regardless of unpleasant thoughts, feelings, and bodily sensations, while choosing one's behaviours based on the situation and personal values.[18] The 'Accept, Connect, Embody' model (a psilocybin therapy model based on Acceptance and Commitment Therapy) capitalises on this concept, working on the premise that psilocybin can enhance psychological flexibility and can catalyse acceptance and connection.[19] Acceptance is defined here as cognitive de-fusion (being able to 'see through' thoughts- observing them rather than fusing with them), present moment awareness (mindful connection to sensory experience, where patients are invited to 'embody' their experience, directing attention to it with intent rather than engage in practices to avoid it), and willingness (the will to change). Connection is defined as 'self-as-context' (where the self is described as a space within which thoughts, emotions, physical sensations, and other phenomena arise, and emphasis is placed on an observer self that can notice these phenomena while building distance from it, rather than identify with them), values (one's idea of what is important in life), and committed action (steps needed to live by values).

Neuroplasticity

Psilocybin appears to offer longevity of symptom resolution after short term treatment,[13,20] rendering it favourable to those who would rather avoid medications requiring daily dosing. This may be mediated by increased neuroplastic changes in the brain. Pre-clinical trials have shown that psychedelics such as lysergic acid diethylamide (LSD) and N, N-dimethyltryptamine (DMT) robustly increase neuritogenesis (the sprouting of neurites e.g. an axon or dendrite from a cell, before differentiation) and synaptogenesis *in vivo* and *in vitro*.[21] Moreover, a recent rodent trial investigating psilocybin showed that a single dose resulted in a 10%

increase in spine size and density which occurred within 24 hours and persisted up to a month later.[22]

Efficacy

Therapeutic effects

Over the past few years, psilocybin therapy has shown promise in preliminary studies investigating its safety and efficacy in substance misuse, Obsessive Compulsive Disorder, Major Depressive Disorder[23,24] and Treatment-Resistant Depression,[25] and end of life anxiety associated with cancer[26] and AIDS.[27] This suggests that psilocybin may be a versatile tool that can be used to alleviate transdiagnostic psychological distress.

Expectancy

A significant number of those who volunteer to take part in trials have previous experience with psychedelics, and they often come with a high expectation of a positive experience.[28] With extensive positive coverage in the mainstream media this bias is likely to become more evident in those who have never tried psilocybin before, perhaps falsely inflating the positive results generated by research. A recent study looking at microdosing of psychedelics showed that, overall, there was little objective therapeutic benefit. However, those who had positive expectancy scores at baseline reported improvement in psychological wellbeing and improvement in depressive symptoms. This suggests a significant placebo response,[29] and highlights the role of this expectancy bias in psychedelic research. At the other end of the spectrum there are those who have been sold the idea of an experience that is a life-changing miracle cure, only to be dissatisfied by the reality. One patient described being 'underwhelmed' and 'disappointed' with the short-term effects of psilocybin and its impact on his life.[30] As positive media coverage of research continues to be present in the mainstream media this experience is likely to be replicated many times over.

Diversity

In the vast majority (70.6%) of psilocybin studies, 75% of all participants were white.[31] This is important because, as Michaels *et al*.[32] point out, we are currently testing a highly specific therapy under narrow conditions on an exclusive group. This is reiterated by Sellers *et al*.[28] who describe the study population as 'Often mainly Caucasian, highly educated living in major urban centers with access to tertiary medical care.' Consequently, clinicians should be mindful that the reality of clinical psilocybin on a broader population may not match the promising picture painted by the research. This is a particular concern when psilocybin is being researched as a treatment for depression as its prevalence is greater in those of a lower socioeconomic status.[33] It is essential that any future phase three trials aim to recruit a more diverse range of subjects to ensure that this imbalance is addressed.

In addition, we should consider whether this narrow pool of study participants could reflect a relatively low interest in medical psilocybin in the general population.[28] The Global Drug Survey (2019) found that only 18% of those who have not tried psychedelics would accept them as a therapy for depression or PTSD.[34]

Therapist input

In clinical trials,[20,23,27] psilocybin is used as an adjunct to psychotherapy; the experience comprises only a part of a larger treatment programme with emphasis on preparation and integration to make the most out of the experience and maximise therapeutic outcome. In this model, therapist input is an essential ingredient. While the therapeutic model itself may change from ACT[35] (Acceptance and Commitment Therapy) to ACE (a model based on ACT, described above in *Psychological Flexibility*), to bespoke models devised specifically for psilocybin, their overall structure remains the same. The Therapist provides support in the process of preparation, dosing and of integrating newly-generated insights into the participants' lives to help lead to changes in cognition and behaviour.[36,37] Furthermore, in this model, a skilled therapist is expected to act as a container for the participant and to support them through challenging experiences that may arise during the session, figuratively (and at times literally) holding their hand as they navigate the more difficult parts of the experience. It has been found that an extended period of overwhelming emotional arousal may be detrimental to treatment outcomes,[38] as well as being very distressing for the patient. The consistency of the delivery of therapist support is fundamental to both efficacy and patient safety,[37] and so it is important that the high standard of training of therapists working in clinical trials is maintained if and when psilocybin eventually makes it into the clinical setting. However, there are some potential barriers to this that should be anticipated and addressed.

Availability of therapist training

Psychedelic therapists who practice in the research setting tend to have undergone training that includes a minimum amount of clinical experience with subjects under the influence of psilocybin.[37] If psilocybin is licenced for clinical use in the next few years it is likely that demand for trained therapists will outstrip supply due to the relatively small number of patients being dosed as part of clinical trials. Steps should be taken to ensure that only those with sufficient training should undertake psychedelic therapy alongside psilocybin. This may mean that patients who would benefit from psilocybin might be denied treatment or end up on long waiting lists. There is some evidence to suggest that a delay in treatment may lead to poorer therapeutic outcomes.[39] How such training of therapists will be encouraged, supported and managed is an as yet unanswered question.

Tai *et al*.[37] have described the development and implementation of a therapist training programme for the phase IIb trial sponsored by Compass Pathways. In order to be eligible to train, participants had to be mental health practitioners with a professional licence in good standing. The trainers were described as 'experts by experience', who had delivered therapy during previous clinical trials. The training programme consisted of 20 hours of online learning followed by 5 days of in-person training. Trainees must then sit in on four psilocybin sessions before they can lead one themselves. Once therapists are competent to lead, they have on-going mentoring and attend webinars so they remain up to date and can share experience. All therapists who took part had committed to a code of ethics to help ensure patient safety.

Therapists' personal experience of psychedelics

Questions have also been raised about how a therapists' own firsthand experience of psychedelics may affect patient outcomes, and as yet there is no research into this.[40] Some are of the opinion that psychedelic therapists who have themselves had a psychedelic experience are better able to be empathetic and effective than those therapists who are psychedelic-naïve, therefore leading to improved therapeutic outcomes.[36] In a climate in which psychedelic drugs are illegal, personal use by professionals is a highly sensitive topic. Those who have used psychedelics may not be willing to disclose this due to fear of stigma or having their work discredited.[36] Both factors may put off professionals training as psychedelic therapists. Going forward it is important to establish the benefit or otherwise of therapist's own psychedelic experience and that barriers other than training are addressed when recruiting professionals into this role.

Cost of therapy

A full course of psilocybin therapy requires a lot of therapist input which is expensive.[41] Sellers *et al*.[28] describe the follow up after the psychedelic experience as 'critical' as the impact on the patient can be very profound. In a publicly funded healthcare system there may be a temptation to economise and cut the time spent with a therapist to the bare minimum. Alternatively, psilocybin therapy may be very difficult to access if it is heavily rationed. Carhart-Harris and Goodwin[41] suggest that a minimum standard be set for therapy and that this should be 'manualised' to ensure the standard is maintained. It is essential that therapist time is not cut to the extent that it affects patient safety.[42]

Potential adverse effects

Within research studies, screening, supervision and setting are carefully controlled and, on the whole, psilocybin is well tolerated by patients. The most commonly reported immediate adverse events are nausea, vomiting, transient anxiety and mild increases in heart rate and blood pressure, with headache being the most commonly reported delayed adverse event.[43] These may be easily managed in the clinical setting.

When used recreationally, there have been reports of acute psychological distress, dangerous behaviour and enduring psychological problems. In a survey study looking at challenging experiences as a result of recreational psilocybin use, 39% of 1993 respondents rated their 'bad trip' as one of the top five most challenging experiences of their lifetime.[44]

Thirty percent of sufferers of treatment-resistant depression will attempt suicide at least once.[45] In the recently released results of the Phase IIb trial sponsored by Compass Pathways, we can see that 5.2% of patients who received Psilocybin reported a serious adverse event, including suicidal ideation and suicidal behaviour.[46] With regards to set and setting, it may be that those experiencing low mood may be in a mind-set that might predispose them to a more challenging experience, and therefore potentially significant distress. More so if it doesn't come to a resolution as it sometimes does with psychedelic therapy. Alternatively, suicidality can be a result of a 'disappointment reaction', where participants with high hopes of a potential treatment falling through, or not achieving desirable results, leads to disappointment and suicidal behaviour. Preliminary results from the Compass phase 2b trial suggest that all patients with suicidal behaviour had a history of suicidal thoughts, and the behaviour took place 1 month after psilocybin administration. In addition, all patients reporting these events were non responders at their last assessment prior to the event or at the time of the event.

That being said, Phase III trials must continue to carefully monitor suicidality following administration of Psilocybin to see how significant a risk this may pose, particularly in patients with preexisting suicidal ideation. At the present time there simply is not enough data around patient safety in this area.

Patient vulnerability

Carhart-Harris and Goodwin[41] talk about the 'special vulnerability' of those under the influence of psilocybin. Sjoberg and Hollister[47] found that those having a psychedelic experience might be more suggestible, meaning that they are more vulnerable than in other types of therapy. Many psychiatric patients have a history of trauma, and so lone working by therapists during dosing sessions should be avoided, to protect both patients and therapists. Sellers *et al*.[28] have also suggested that ideally the two professionals accompanying the patient should never both be of a different gender to the patient. Chaperones are currently used in the research setting. However, in a busy clinical setting that may be short-staffed, there may be a temptation to go without. In order to protect both patients and therapists, chaperones should be considered mandatory.

Patients with psychiatric co-morbidities

Existing psilocybin studies have been highly selective and excluded patients with psychiatric comorbidities, and so the risks associated with psilocybin in this group of patients has not been very well explored. This means that results may not be generalizable and there may be significant risk associated with using psilocybin in naturalistic clinical practice where comorbidity is the norm rather than the exception.[28]

Potential for abuse

With psilocybin being known first and foremost as a drug of abuse, would use of psilocybin in the clinical setting lead patients to seeking it in the community? Furthermore, if psilocybin became a licenced medication would it encourage people to seek it themselves to self-medicate outside of controlled clinical settings and without the guidance of therapists, where they are more likely to experience adverse effects? We know that users quickly become tolerant following repeated doses of psilocybin. However, physical dependence does not develop.[10] Psilocybin has much less potential for abuse than other psychoactive drugs,[43] but diversion and abuse of prescription medication is a recognised problem and there would likely be concern around greater access to psilocybin by the public.[28] There are documented incidences of those given psilocybin as part of a trial successfully obtaining it afterwards in the community: In a trial carried out by Carhart-Harris *et al*.[13] 5 of the 20 patients dosed did so. This may be because of patients seeking help for their symptoms after the positive effects of dosing had worn off, as has been seen in patients followed up longer term.[13] It is important to differentiate between an individual taking psilocybin to regain therapeutic benefit from drug dependency. It is also important to highlight the risks of taking psilocybin outside a controlled setting and provide harm reduction information where appropriate.

Ethical considerations in psychedelic therapy

Langlitz *et al*.[48] beautifully highlight a somewhat idiosyncratic challenge to psychedelic therapy that may not be as prominent in other psychopharmacological interventions; namely the subject of moral psychopharmacology.

Potential Pitfall	Proposed solution
Current studies have had non-diverse subject populations, not reflective of patients who may benefit from Psilocybin in the clinical setting.	Phase III trials to recruit a more diverse and representative group of subjects.
Stigma; psilocybin may be considered a drug of abuse amongst both patients and professionals.	Inclusion of psychedelics, including proposed mechanisms of action, potential clinical uses, and balanced information around addiction potential into training curricula for mental health professionals.
Risk to patients due to vulnerability under the influence of Psilocybin.	Ensure chaperone provision by making it mandatory.
Patients self-medicating in the community with illicit Psilocybin, or psilocybin-containing mushrooms.	Where appropriate, provide harm reduction advice, highlight risks of outside of a controlled setting.
Shortage of trained therapists, leading to greater difficulty accessing Psilocybin therapy, or those with insufficient training delivering therapy.	Minimum training standards to be set, and training to be manualised. Mental health trusts to support Psilocybin therapist training where able.

Figure 1. Table summarising proposed solutions to issues that might arise if Psilocybin becomes a licenced medication.

Psilocybin, among other psychedelics, has been associated with changes in character and social cognition.[49] For example, three months after psilocybin treatment, patients showed an increase in extraversion and openness scores,[50] with some patients reporting an ability to re-connect with close relationships, including people who had wronged them.[51] There was also a significant increase in nature relatedness (subjective connection to nature), sustained up to a year after administration.[52] Participants taking part in a smoking cessation trial described engaging in prosocial and altruistic behaviours after their psilocybin sessions,[53] and psilocybin was shown to reduce altruistic punishment as rejections were reduced in the ultimatum game[54] and 'social pain signals' in the Cyberball game, suggesting that it attenuates responses to negative stimuli correlating to changes in self-processing rather than a lack of awareness of their exclusion.[55]

Although other substances can also alter social cognition and behaviour,[56-58] the importance of context and the 'noetic quality' ascribed to psychedelic experiences renders their users particularly vulnerable to these changes, with these characteristics acting as a 'double edged sword'[59] in terms of benefits and harms. Psychedelics ingested in different settings have been utilised to induce different, and sometimes opposing changes, from liberation from society to aides of initiation and integration into society, and from inducers of unity and connection to tools used in rituals to prepare for conflict.[48] Context and culture have a profound influence on the malleable state of mind that occurs with psilocybin, which is only intensified by the sense of revelation and intrinsic 'knowing' reported by users, reducing the need for external validation of these revelations. Timmermann *et al*.[59] highlights the influence of these factors as seen in the rising of false memories in clinical settings, the influence of spiritual beliefs at retreat centres on their attenders, and meta-physical explanations given to experiences while under the influence of DMT. The potential for iatrogenic harm that could arise as a result of this is clear, especially as psychedelic use becomes more mainstream and extra-pharmacological factors become more diverse.

It is therefore important that special care should be given to the consent process and to psychoeducation around the use of psychedelic substances. It will certainly be a challenge to standardise this and fine tune the process to maximise benefits and reduce harms as psilocybin moves into the clinical setting.

Conclusion

It may indeed be the case that psilocybin facilitates the relaxation of long-held beliefs, which under a therapeutic framework can lead to revision of such beliefs and translate to enduring therapeutic benefit, outlasting its acute effects.[60] This would make it a valuable and versatile tool in the treatment of several mental disorders when utilised with the appropriate therapeutic support.

However, there are several measures that need to be taken to ensure future patient safety, summarised in Figure 1. Ideally future phase 3 trials should recruit study populations that better represent the full population for whom this treatment is intended. This will make the results more generalizable and will minimise the risk to those patients who fall outside the very narrow existing study population. There is also the need for more information about long-term effects before psilocybin can be used in psychiatric practice.[61] Moreover, it is important to be aware of both the expectancy bias that seem to accompany psychedelics among proponents of their use, and the negative connotations they have among those who are not so inclined. There is a need for a balanced portrayal of both positive effects and potential pitfalls, where psilocybin and other psychedelic substances can be viewed through a critical, evidence-based lens without the weight of negative cultural stigmas or unrealistic expectations. One aspect that may support this is the incorporation of modules on psychedelic substances and their effects within training curricula for mental health professionals. Finally, it is paramount that strict standards around therapist training, chaperone provision, and course of therapy are maintained in clinical settings to maximise benefits and minimise risks. This list of considerations is by no means exhaustive and is sure to grow as more research is conducted. A stance of openness, curiosity, and willingness to change is essential as we slowly understand how to work with this powerful substance.

Are Psychedelics Useful in the Practice of Buddhism?

by

Myron J. Stolarof

Journal of Humanistic Psychology, Volume 39, No. 1, Winter 1999, pp. 60-80

In the fall of 1996 issue of the Buddhist magazine Tricycle, various teachers of Buddhist meditation practice commented on the value of psychedelic experiences, with opinions of them ranging from helpful to harmful. Here, the author hopes to explain these conflicting viewpoints by describing important aspects of employing psychedelics that must be taken into account for effective results. These embrace proper methodology, which includes set and setting, dose levels, appropriate substances, appropriate intervals, and proper integration of each experience. The author has found the informed use of psychedelics to be a valuable tool in accelerating proficiency and deepening meditative practice and offers recommendations for successful use. The adverse comments of several recognized teachers are evaluated to shed further light on fruitful application of psychedelic substances.

AUTHOR'S NOTE: *The author wishes to express his appreciation to the management and editors of Tricycle for their special issue on psychedelics and to all the contributors for their willingness to present their views on a controversial subject.*

The Buddhist magazine Tricycle devoted its fall of 1996 issue to the topic of psychedelics and Buddhism. The viewpoints of the authors regarding the efficacy of psychedelics on Buddhist practice ranged from a high degree of support to outright opposition. Those who are interested in the possible application of psychedelics to meditative practice might well be puzzled by such a diversity of viewpoints. Yet, the answer is simple. Psychedelics can be used in a great variety of ways for an enormous array of purposes. The results depend greatly on the experience, knowledge, skill, and level of development of the practitioner. Thus, the person presenting his and/or her own particular point of view may or may not be aware of numerous other considerations involved. Widespread unfavorable public bias toward psychedelics has been created by very selective reporting by the media, as observed by Walsh (1982). As Walsh reports, this bias is so unfavorable that a reputable journal refused to accept an article that indicated some beneficial outcomes from the use of psychedelics unless the reference to positive effects was removed. I hope to shed some light on the diversity of viewpoints by first laying out what I consider to be important factors to take into account in effectively employing psychedelics. From this perspective, we can examine some of the more relevant comments that have been expressed.

Psychedelic agents, when properly understood, are probably one of the most valuable, useful, and powerful tools available to humanity. Yet, their use is extremely complex, which means that they are widely misunderstood and very often abused.

Let me be clear: It is not psychedelics that are complex. In their most useful application, they play a rather straightforward role. After 40 years of careful study, it is my observation that one of the outstanding actions of psychedelics is permitting the dissolving of mind sets. One of the most powerful mind set humans employ is the hiding of undesirable material from consciousness. Thus, a very important function of psychedelic substances is to permit access to the unconscious mind. The unconscious mind is enormously complex and possesses an extremely wide range of attributes, from repressed, painful material to the sublime realization of universal love. We probably shall never cease to discover new aspects and dimensions of the mind, as it appears endless, and I am convinced that continual searching will reveal new discoveries.

Probably every hypothesis that any scientist, therapist, or mystic has conceived ultimately can be observed to fit some set of conditions, from psychological dynamics to the ultimate nature of the universe. One of the most remarkable things to the experienced psychedelic user is discovering how the boundaries of perception dissolve to permit viewing ever new images, perceptions, concepts, and realizations. The biggest problem lies in incorporating discoveries into meaningful, enhanced functioning in life.

Humans love structure, and at the same time, the ego loves certainty, so a great variety of claims often are made about what psychedelics can or cannot do. With integrity, commitment, and courage, vast aspects of the mind can be explored. It is important to realize that what one experiences depends a great deal on his/her value-belief system, motivation, conditioning, and accumulated unconscious content, which includes the rigidity with which the mind functions.

I am an early stage novice in my practice of Buddhism, so there is a great deal about the subject of which I am ignorant. However, I have had considerable experience with psychedelics, and my major concern is that there will be attempts to categorize these potent aids and contain them within the walls of narrow, judgmental decisions, thereby cutting off much potential usefulness.

I personally have found that appropriately understood and used, psychedelics can play a significant role in deepening and accelerating the progress of one's meditative practice. This is not true for everyone. Psychedelics are of little use for advanced practitioners who have learned to achieve results without the benefit of such aids or for those who can free themselves from worldly obligations for extensive daily practice. Also, encountering heavily defended areas in the psyche with psychedelics may produce intense, uncomfortable feelings that many may prefer to work through more gradually.

My concern is mostly for the large number of people who could benefit from fruitful meditation practice but must still be occupied in the world by earning a living and raising a family. Such persons lead busy lives and may not have the time to devote to perfecting a practice that will lead to significant freedom. For these, informed use of psychedelics can be quite helpful in more rapidly reaching the level of accomplishment at which practice becomes self-sustaining. The ultimate achievement of liberation must occur through interior development that does not depend on the use of a plant or a chemical, although these may help in discovering the way.

There are several key factors to consider in evaluating whether the use of psychedelics can be personally fruitful:

1. **Legal status.** In a sense, this discussion is hypothetical because now most psychedelics are illegal to possess in the United States. Westerners for several centuries have focused primarily on the outer world, with the resulting neglect of developing inner resources. This neglect, coupled with a heavy emphasis on materialism and reductionism, has created a painful schism between adopted conscious values and the deep interests of the Self. For most people, it has become so painful to reveal this powerful conflict that those substances that might accomplish this have been made illegal to possess. This has not stopped many dedicated therapists and seekers who find that the value of such substances exceeds the risk of incarceration. The illegal status also creates the problem of finding pure substances in reliably known dose levels. I am not advocating that anyone break the law, but I am pointing out the importance of developing sound, rational policies that will permit appropriate scientific evaluation of these substances and, ultimately, the realization of their potential.
2. **Methodology.** It is important that those who wish to work with psychedelics be fully informed of appropriate procedures. Unfortunately, the illegal status of psychedelics has prevented the publication and sharing of results and effective practices. However, there is available a great deal of information to guide the serious seeker if one has the diligence to seek it out. Some excellent examples of appropriate procedures can be found in the following references.
   Grof's (1980) book, *LSD Psychotherapy*, is a treasure house of good information. See in particular the sections Psychedelic Therapy With LSD (pp. 32-38), Personality of the Subject (pp. 52-64), Personality of the Therapist or Guide (pp. 89-107), and Set and Setting of the Sessions (pp. 108-116).
   In Adamson and Metzner (1988), much attention is given to guidelines, preparation, set and setting.
   The pamphlet, *Code of Ethics for Spiritual Guides*, was prepared by the Council on Spiritual Practices, which can be contacted at the following address: Box 460065, San Francisco, CA 94146-0065.

Finally, Stolaroff (1993) presents a brief summary of important factors to take into account.

3. **Low doses.** Many who have experimented with psychedelics have used high doses of substance to assure penetration into the very rewarding transpersonal levels of experience. Such experiences can be awesome, compelling, and extremely rewarding. Yet, it is often the case that these experiences fade away in time unless there are diligent efforts to make the changes indicated. In profound experiences, the layers of conditioning that, in ordinary states, hold one away from liberation are transcended and from the lofty view of the transcendental state, personal conditioning seems unimportant and often unrecognized. Yet after the experience, old habits and patterns reestablish themselves and often there is no alteration in behavior. The use of low doses often can be much more effective in dealing with our "psychic garbage." Many do not care for low doses because they can stir up uncomfortable feelings, and they prefer to transcend them by pushing on into higher states, but it is precisely these uncomfortable feelings that must be resolved to achieve true freedom. With low doses, by focusing directly on the feelings and staying with them without aversion and without grasping, they will in time dissipate. Resolving one's repressed feelings in this manner clears the inner being, permitting the True Self to manifest more steadily. Such a result provides greater energy, deeper peace, more perceptive awareness, greater clarity, keener intuition, and greater compassion. It permits the deepening of one's meditation practice. The surfacing of buried feelings that this procedure permits often can bring new understanding of one's personality dynamics.
4. **Different compounds.** Some compounds may be more suitable for developing meditation practice than are others. I personally have had substantial experience with the phenethylamines, outstanding examples of which are 2C-T-2, 2C-T7, and 2C-B (code names for 2,5-dimethoxy-4-(ethylthio) phenethylamine, 2,5- dimethoxy-4-(n-propylthio) phenethylamine, and 4-bromo-2,5-dimethoxyphenethylamine, respectively). The synthetic procedures and physical characteristics of all of these compounds are published in Shulgin and Shulgin (1991). These compounds have the characteristic of having some of the centering qualities of MDMA, yet being more LSD-like than is MDMA without the powerful push of LSD. This lowers the likelihood of the user being trapped in deep pools of repressed material. Not being as pushy as LSD, these compounds require developing volition to achieve similar levels of experience. This is the same kind of volition that develops good meditation practice. Consequently, it is easier to focus attention under their influence, which permits developing the attributes for good meditation practice. As one develops proficiency in entering the desired state, it is found that the advantage of one compound over another diminishes. The appropriate dose (found by experiment-generally equivalent to 25-50 micrograms of LSD) of most any long-acting psychedelic is helpful.
5. **Freeing deeply occluded areas.** The practice of Buddhism in general, as I understand it, is not necessarily therapeutically oriented. There is much advice in older texts to resolve personal problems with focused attention and application of intention to change behavior. The result is that much unconscious material never gets resolved despite the ability of the mind to achieve high levels of awareness. For a discussion of the difference between meditative realization and the uncovering process achieved through psychotherapy, see Wilber (1993, pp. 196-198). Psychedelics facilitate reaching these deeper, often highly defended levels and clearing them out, thus permitting greater liberation and dropping of undesirable personality and behavior patterns. Some powerfully repressed areas, such as the very painful birth experience! underwent in my first LSD session (Stolaroff, 1994), might never be resolved without the help of psychedelics.
6. **Judicious spacing of psychedelic experiences.** In my own practice, I intentionally have limited my early morning formal meditation session to an hour so as to leave ample time for worldly endeavors. Thus, whatever I discover will be more applicable for the large numbers of persons constrained by the need or desire to function in the world. Although I have advanced sufficiently in my practice to fend off some of the typical aging symptoms (I am 77 years old) such as loss of energy, stiff and sore muscles, and increased arthritic symptoms, I do find that after a while, I begin to acquire such symptoms. When this happens, an appropriate psychedelic experience is a very effective rejuvenator. Aging symptoms summarily are dissipated, I am in a much more enjoyable and effective state of being, and I find it easier to remain in this state through my regular meditation practice. Also, if there are deep, underlying, unconscious dynamics that are a drag on life, as I have experienced much of my life, I find it especially helpful to resolve such deep patterns with psychedelics. The psychedelic experience provides extremely effective clearing and a quantum jump improvement in well-being and meditative proficiency. At the same time, it is important not simply to rely on another experience to overcome difficulties. Numerous

times I have discovered that mustering a deeper degree of intent can resolve important restrictions through properly focused meditation practice, with the advantage of a more permanent and satisfying state of well-being. Such work also ensures that when an additional experience is found to be appropriate, it will be considerably more rewarding.

7. **Honoring the experience.** A very important aspect of employing psychedelics is to acknowledge fully the graces that have been received. This is done through appreciation and gratitude, which are best expressed by determinedly putting into effect in one's life the changes that have been indicated. In fact, failure to do so can contribute to subsequent depression. Thoroughly honoring the experience and postponing further psychedelic exploration until a real need is determined that cannot be resolved in straightforward meditation practice ensures that the next experience will be fruitful. One of the fairly widespread abuses of psychedelics is to rely on repeated use of the drug to accomplish relief from discomfort instead of exerting the effort to make changes in one's behavior that have already been indicated. This is the most frequent objection to psychedelics raised by the contributors to Tricycle (1996).
8. **Historical precedence.** Psychedelics have had extensive use in spiritual practices in numerous cultures around the world and encompassing some 2,000 years of history. Current legally sanctioned spiritual practices with psychedelics include the Native American Indian church in North America, based on the use of peyote, and the Santo Daime and União do Vegetal churches in Brazil employing ayahuasca. Robert Jesse (1996) briefly reviews the history of such usage and describes a number of the substances most widely employed-peyote, mushrooms, ayahuasca, soma, kykeon, iboga, cannabis, LSD, and MDMA.

Using Psychedelics In Meditation Practice

Since the passage of the Controlled Substance Analogue Enforcement Act of 1986, almost all psychedelic substances have been outlawed: As a consequence, it has not been possible to conduct legally any research since that time. The following suggestions are based on the limited amount of experience that has been garnered, most of which is personal, and indicate where future research can be gainfully directed.

1. **Ethical framework.** Committing oneself to a suitable ethical framework, such as the Buddhist eight-fold path, is essential. This is an important part of the mental set and also provides help in integrating psychedelic experiences.
2. **Preparation.** The participant should have a thorough understanding of psychedelics including the types of experience that may be expected, factors affecting experience, how to handle various kinds of experiences and how to follow them up, and the importance of set and setting as described above. It is important to have first undergone a high-dose experience with a qualified guide that has resulted in reaching transpersonal levels. This will put the entire process into perspective.
3. **Employing a correct substance at the proper dose level.** Described above.
4. **Developing mental stability.** This application is probably the most fruitful for employing psychedelic substances. A practice focusing on the breath is particularly appropriate. With proper substance and dose, one will note several possible developments. First, distractions may be more intense than in ordinary practice because the action of the chemical releases more material from the unconscious. At the same time, the enhanced awareness resulting from the action of the psychedelic allows one to notice in greater detail how various attitudes, thoughts, and actions affect the ability to hold one's focus steady. From this, one learns to hold the mind in the position of maximum effectiveness for becoming free of distractions and for holding mental focus stable. One then experiences the deepening of the practice, more readily avoiding distractions and moving into areas of peace, calm, and growing euphoria. With continuing practice, one finds it easier to enter the numinous levels that one ultimately is seeking. Furthermore, the volition gained in developing this practice under the influence of a psychedelic carries on into day-to-day practice during which the same level of achievement becomes accessible. The outcome that I personally have found most satisfying is the ability to hold the mind perfectly still, a state that makes access to previously unrevealed regions of the mind available, including the direct contact with one's essence or divinity.
5. **Deepening the meditation practice.** One's daily practice may be strengthened by using the discoveries made under the influence of psychedelics. I recommend working to obtain maximum benefit from one psychedelic experience before proceeding with another. When experiences are spaced

> judiciously in this manner, one learns under the influence to go deeper into the contact with the numinous. As the ability to hold the mind steady grows, it becomes possible to focus more directly on the contact with the inner teacher-our deepest Self, our Buddha nature, or however one chooses to call the wise, guiding entity within us. Maintaining this focus leads to what seems to me to be the most valuable, fulfilling experiences possible. From such experiences, combined with daily practice, grows the ability to achieve similar results in ordinary practice, until eventually the use of the psychedelic substance is no longer required. At this point, the faculty for achieving optimum results has been developed within us. I like to call this "developing a God muscle."
>
> Many of the issues concerning the application of psychedelics in meditative practice may be clarified further by examining some of the comments reported in the Tricycle issue on Buddhism and Psychedelics (Tricycle, 1996). Jack Kornfield (1996) presents a knowledgeable and well-balanced view of the use of psychedelics as well as important factors required for a good meditative practice and spiritual development. He points out the value that psychedelics have in introducing persons to new areas of the mind and even to glimpses of the goal of spiritual realization, experiences which encouraged many to develop a more disciplined practice. He also clearly points out a common failing among many psychedelic users: failure to understand the depth of change required to transform oneself and to understand that it takes more than repeated psychedelic experiences to accomplish this.

Next, I will present some responses to Michelle McDonald-Smith's (1996) firmly expressed views.

> From my experience, no matter what kind of deep opening one might have on a drug, it isn't going to develop one's ability to have those experiences naturally. Other people might say that drugs are a doorway, but I don't see them developing anything. They don't develop equanimity, they don't develop concentration, they don't develop any factors of enlightenment. (McDonald-Smith p. 67)

In sharing my own perceptions on the same factors she has enumerated, I wish it to be clear that I am discussing the results of informed used, which has been delineated elsewhere in this article.

I agree that psychedelics alone will not necessarily develop the ability to have transpersonal experiences naturally, despite the fact that many people who have had such an outstanding initial experience are content to never have another, feeling that they have been blessed for life. I maintain that psychedelics are way showers, and we then must work with serious intent to attain the states that are shown to be possible. Nevertheless, it is of enormous benefit and inspiration if one can glimpse and experience firsthand the territory to which we aspire. Norbert Wiener, the Massachusetts Institute of Technology scientist who suggested the binary system on which the operation of computers is based, commented on the successful development of the atomic bomb by the Russians. He stated that their simply knowing that it is possible was at least 50.

In contrast to McDonald-Smith's (1996) claim, "I don't see them as developing anything"(p.67), I see them as developing wisdom, heightened perception, self-understanding, energy, and freedom; releasing habitual blocks that interfere with the total response of our senses; facilitating the flow of ideas; releasing intuition and creativity as unconscious blocks are removed and as we become in touch with our inherent faculties; and deepening our meditation practice. My observations are based on some 40 years of research, including observing more than 100 individuals.

Regarding the comments about equanimity, concentration, and enlightenment, I find that appropriate use of psychedelics helps develop all of these qualities. I never realized what equanimity was until I began taking psychedelics. One of the great gifts of psychedelics is permitting one to learn real concentration. Of course, if there is much repressed material in the unconscious and one takes a significant dose of a psychedelic, it is neither possible nor desirable to try to concentrate. It is best to simply surrender to the experience and to let the flow of imagery and feelings proceed undisturbed. In this flow, unconscious material is released. The meditation equivalent is focusing on the breath or on an object and simply letting thoughts and feelings flow without getting involved. When the high-pressure feelings in the unconscious demanding release begin to abate, then it becomes possible to concentrate on the desired object. The practice of holding one's attention steadily on an image, concept, or object under the influence of a good psychedelic permits many aspects of the object of attention to unfold, so that one may learn a great deal of new information about the object as well as discover unsuspected beauty and meaning and experience appreciation. Eventually, one develops concentration sufficient to hold the mind quite still, which permits other aspects of reality to manifest. I often feel that this is creating the empty space to permit God to enter, which I consider a major factor of enlightenment. In practicing holding the mind steady under a low dose of a psychedelic, one becomes much more aware of the subtle distractions and urges that affect concentration. Some distractions are more intense, so one can practice maintaining stability in spite of them. Such practice under the influence helps strengthen the faculty that maintains steady attention. A great deal can be accomplished in learning to effectively maintain stability, learning which is immediately applicable in subsequent practice.

McDonald-Smith (1996) stated:

> Drugs take a considerable toll on the body and the mind. They bring all this energy into the system so that it catapults you into a different state of consciousness at the same time that it taxes your body, mind, and heart. You get a sort of beatific view, but actually you are further down the mountain. (McDonald-Smith p. 67)

My associates and I, in psychedelic research, find ourselves very much at odds with this statement. Yes, if a person is carrying heavy psychic burdens and takes a large psychedelic dose, he or she can be very tired at the end of the day and perhaps for a few days after. But often this is followed by a gratifying sense of rejuvenation and appreciation for the benefits realized. Important exceptions are the cases in which the participant does not work all the way through important problem areas, leaving them with a feeling of unfinished business and perhaps even greater discomfort because he or she is now experiencing uncomfortable feelings that formerly were locked safely away. Working through these feelings with the help of a good counselor and following up with subsequent psychedelic sessions can clear up this problem.

Rather than toll, there is healing and rejuvenation. One often feels that he or she has dropped a heavy load off the body, and his or her spirits are high. A heavier mind can come from the unresolved situation described above; otherwise, there is lightness of feeling and clarity of mind. Other than toll, there is renewal. I have friends who take many different kinds of vitamins and nutriments to achieve healthy states of mind and body and to have more energy. I try their various recommendations, but my experience is that none of them work as well as a good, appropriate psychedelic session. Rather than being brought further down, you are climbing the mountain with considerable help. It is very true, however, that to maintain the high states experienced, it takes committed effort to make the necessary changes in day-to-day life. This point is frequently neglected. My experience is that not expressing appropriate gratitude and appreciation for the marvelous graces that have been granted can lead to self-hatred and depression. A good meditation practice is an effective means of maintaining awareness of the needed changes and furnishing the energy and motivation to make them possible.

McDonald-Smith (1996) also stated:

> I've had people come to retreats who've done a lot of drugs, and it seems like they don't have the energy to access subtle stages of insight. They've blown it off with drugs. You pay a price for any drug experience. (McDonald-Smith p. 69)

It is true that many have abused psychedelics by frequent use, probably of high doses, with insufficient effort to integrate the meaning of the experience. Frequent repetition can dissolve ego strength, and such people can develop rambling minds and have little ability to focus. However, it is important to understand that this is the result of abuse, which is net the case with informed use. You do not "pay a price for any drug experience." Appropriately used, psychedelic experiences not only have little or no price, but also open the door to healing, rejuvenation, and many riches in life.

McDonald-Smith (1996) says: "On the deepest level of letting go, drugs get in the way. This is especially true for those who are heavily armored" (p. 69). I say that appropriate use of psychedelics teaches you to let go and discover the rewarding benefits of letting go. We are all afraid of the unknown; psychedelics can help one develop trust, face fear, and enter unknown and sublime arenas. Psychedelics are especially helpful for the heavily armored, if they truly wish to resolve their difficulties, as they can help dissolve the heavy walls of defensiveness and permit resolution and profound insight.

A major emphasis in the remainder of McDonald-Smith's (1996) article is that "drugs promote attachment to peak experience... what you actually get from drug experience is the desire to take the drugs again" (p. 70). Many have fallen into this trap, but it is an overstatement to generalize that this is always the case. With an honest approach, one realizes that there is work to do before seeking another session. My own experience is that for many of us, particularly with me for many years, our self-esteem is so low that we feel that we do not deserve the full benefits of grace. I have found that extensive help is waiting in many different forms and from many different levels and is generously offered. We can always benefit from taking advantage of help in whatever mode, be it teachers, nutriments, reading, exercise, prayer, or simply thinking good thoughts. And they can all work together and support each other. Appreciation and gratitude multiply the benefits. And one certainly cannot argue with McDonald-Smith's advice to be completely aware in each moment.

Allan Hunt Badiner (1996) has written in Tricycle an impressive description of an extremely powerful, remarkable, life-changing experience with yagé. His experience probably represents the far extremes of intensity, variety, complexity, and meaning that psychedelics have to offer. Badiner is to be highly congratulated for both his courage and his power of articulation in encountering and describing this compelling experience. There are probably not a great many persons prepared to make such an encounter, but the outcome of Allan's experience is testimony to the advice given by many sages that the encountering of pain and suffering, and even of near death itself, paves the way to becoming utterly alive.

Nina Wise (1996), in her article in Tricycle, tells a beautiful story of personal growth and development with the aid of psychedelics, excellent teachers, and dedicated practice. With her first psychedelic experience, she encounters a trauma often encountered by inexperienced explorers. She has a glorious, very opening experience, yet sinks into deep depression because she does not know how to integrate the experience to maintain such a state. She finds a meditation teacher and begins to grow in her practice. A subsequent experience with ayahuasca provides another important opening that has very meaningful consequences in her life. Later, with the help of good meditation teachers, she reaches the peace and equanimity she has been searching for and is no longer attracted to the aid offered by psychedelics. She has reached the state of realization for which most of us long.

One hardly could hope for a better outcome than that which Nina Wise presents to us. Yet, her story does provide the opportunity to include some additional remarks about the use of psychedelics. Her first experience points out the need, as almost all the knowledgeable writers in the Tricycle (1996) issue have clearly stated, to have a framework and discipline within which to have the experience and, particularly, to help follow up the experience for optimum benefit. Her second experience with ayahuasca illustrated that at an appropriate time, a further experience can be quite helpful.

There were characteristics about her psychedelic journeys that she was quite happy to leave behind her and not engage again. Wise's (1996) words are, "My psychedelic experiences, which had brought me to this place, were now interfering with my vision" (p. 93). It is important to understand that psychedelics, when properly employed, can lead to the same state she had achieved of direct experience of reality. It is the state reached by what I call the trained user. It helps to know that the creepy visions, the hallucinations, and the constant flow of imagery are the results of pressures in the unconscious where repressed material is demanding release. By employing low psychedelic doses, it is possible to confront and deal with these images and, particularly, the feelings behind them, until they clear up. Then one reaches, while under the influence, the stage of immediate perception (Sherwood, Stolaroff, & Harman, 1962). "In this stage, the psychosomatic symptoms, the model psychoses, the multicolored hallucinatory images tend to disappear. The individual develops an awareness of other aspects of reality than those to which he is accustomed" (p. 71). The fact that a psychedelic produces streams of imagery indicates that the interior barriers to the center core of the self have not been completely eliminated. For those who wish to be completely liberated, psychedelic experiences, properly timed and integrated, can be very helpful in resolving repressed material and defensive blocks, thus giving freer access to the divine within.

Trudy Walter (1996) has given us a touching story of the difficulties of addiction and the hardship of breaking it. For years, she took respite and enjoyment in "getting stoned," and it was only through dedicated commitment to her meditation practice that she could free herself from her addiction. No matter how enjoyable or helpful an aid can be, eventually, as stated so clearly by Frances Vaughan (1995), these "golden chains" must be transcended to develop the capabilities of our true inner self.

Robert Aitken (1996) states: "I don't think drugs have particularly helped anybody arrive where they are" (p. 105). This is most definitely not true for me and many others whom I know. I very much agree with his observation that many desperately are trying to achieve realization through the drug experience when what is required is hard work in changing their attitudes, values, and behavior-a process facilitated much more effectively through deepened intention and improved behavior than through overuse of psychedelic chemicals.

Aitken (1996) offers evidence that being under the influence and then later trying to practice does not work. This has been commented on by other teachers, and I am sure that it is true for many. However, the situation is quite complex, and care is required to evaluate such generalizations. A great deal can be learned about how to use psychedelics appropriately to enhance and deepen practice. It requires looking at a number of considerations. What is the substance, the dose level, the frequency, the intention, and the effort to make maximum use of the experience, regardless of whether it was pleasant or uncomfortable, or the effort to deal with indicated changes in values and actions? With agents as powerful as psychedelics and the vast regions of the human mind made available, it seems quite shortsighted to draw conclusions before thorough investigative efforts have been pursued. And of course, with the current legal status, one dare not publish or publicly share results, so that it is most likely that there exists a great deal of valuable experience that remains hidden from the public eye.

It is my experience that practice with an appropriate, moderate dose of a psychedelic permits deepening of the meditation practice and learning much more rapidly to avoid distractions and concentrate on the important aspects of the practice. Because of our unfortunate drug laws, it has not been possible to replicate my findings on a broad basis, although preliminary trials with others support my own experience and the validity of my hypothesis. I am sure that we must find ways to verify procedures that offer such promising accomplishments.

Aitken (1996) observes that those who returned to a retreat from psychedelic experiences demonstrated a deterioration in their ability to meditate. I personally deem it unwise to muddle the opportunity to learn what a retreat has to offer by interspersing drug experiences.

Aitken (1996) is certainly right to raise the question, what after the experience? There is now almost universal consensus that being shown the territory is not enough. It is extremely important to consummate the experience by bringing it to full fruition in day-to-day life. Commitment to an ethical way of life, supported by a good meditation practice that enhances stability and clarity, is one of the best ways to ensure this accomplishment.

Aitken (1996) again says that you do not have to take drugs to wake up to reality. This is certainly true, and a great many will choose the meditative path. But for many others, the appropriate use of psychedelics can rapidly hasten the discovery of reality and, furthermore, can help reveal the inner blocks that hold one from reality and even temporarily dissolve them, so that one develops a clear picture of how to stay in touch with reality. Without psychedelics, it can take many, many months of hard work to obtain the same vision, and after the vision is obtained, there may still be repressed inner psychic loads that can inhibit freedom, suppress the experience of one's feelings and senses to the fullest, and preclude living constantly out of one's essence or Buddha nature.

There no doubt are many who have turned away from psychedelics because of unsatisfactory experiences. Although psychedelics are not a path for everyone, it is possible to cultivate more favorable outcomes with a better understanding of the nature of the experience, the possible varieties of dynamics that can arise, and how to deal with them. Those who confront and resolve negative experiences can come out with a good deal more understanding and relief from psychic burdens, which can result in greater energy and well-being.

Aitken (1996) states "that there is a qualitative difference between the ecstasy that some people report from their drug experiences and the understanding, the realization, that comes with Zen practice" (p. 109). I am not familiar with Zen practice, and so I may be in no position to comment, as Aitken likewise may not be in a position to comment on the ecstatic experience some achieve through psychedelics. But I do know from firsthand experience that it is possible to experience ecstasy almost beyond what the human frame can stand, and if Zen practitioners reach this state, power to them.

Joan Halifax (1996) clearly understands a great deal about psychedelics and what they can do and, at the same time, has developed her practice to a point at which psychedelics are no longer necessary. In her description of outgrowing the need for psychedelics, she states that the qualities of stability, loving-kindness, clarity, and humbleness are the primary qualities of the mind cultivated in meditation. She further states that such quailties are not necessarily cultivated by psychedelics. This statement is certainly true for some users who have been deceived and even become burdensome know-it-ails through their psychedelic use. I personally have found that psychedelics have been powerful influences in developing all the qualities that Halifax mentions. I already have commented that the appropriate mixture of meditation and psychedelics can influence strongly the effectiveness of each practice.

I am very much encouraged by the positive results I have observed during several decades of investigation. I find psychedelics to have significant potential not only in aiding the development of meditation practice, but also in many other important areas. Unfortunately, this perspective is not generally shared, and the controversy over psychedelics continues to be one of the major scientific disputes of recent history.

A number of excellent articles have been published examining this controversy and/or providing additional information for better understanding psychedelics. Clark (1975) presents an insightful article based on 100 respondents to a questionnaire study to assess views on promising areas of psychedelic research, the extent of the promise, and the difficulties in conducting research. A strong recommendation is made for opening up and funding psychedelic research. Villoldo (1977) describes the work of Salvador Roquet, who developed very intense methods of conducting group psychedelic sessions with powerful impact, perhaps the most intensely focused procedure yet evolved. Many important aspects of successfully employing psychedelics in therapy are discussed. Klavetter and Mogar (1967) make a questionnaire analysis of participants completing the psychedelic program at the International Foundation for Advanced Study in Menlo Park and convert the data into peakers and nonpeakers following Maslow's (1962) definitions. Peakers consistently report significant therapeutic benefit following the LSD session, a result confirmed by Hoffer (1965) and Pahnke and Richards (1966). Stolaroff (1997) presents an in-depth interview with one of the most accomplished psychedelic therapists of our time, now deceased and unnamed because of our current drug laws. This book covers the successful development of both individual and group experiences, selecting the most effective of a variety of psychedelic substances, and the optimum progression of their application.

Baumeister and Placidi (1983) present a fairly complete review of the LSD controversy, citing interesting and insightful reasons for the positions taken. Kurtz (1963) presents a cogent comparison of religious mystical experience, nature mystical experiences, Maslow's (1962) peak experiences, and drug-induced experiences. His analysis provides conclusions that the drug experiences of unity, when they occur, are the most inclusive and comprehensive in including all aspects of reality and the totality of human consciousness, combining intellectual, sensory, and mystical aspects occurring simultaneously. Mogar (1965) provides an excellent review paper, pointing out the growing trends in psychiatry and psychology and the growing acceptance of a wider range of human capacities and functions as revealed through altered states of consciousness produced by a variety of means. An excellent summary of results obtained in psychedelic research is presented.

Harman (1963) presents probably the most informed review of the psychedelic drug controversy, recognizing the root of the controversy in basic metaphysical assumptions, carefully describing the character of psychedelic experiences and the factors that influence them, comparing the highest potential of such experiences with natural mystical experiences, presenting the data assuring safety in proper hands, analyzing the resistance to accepting psychedelic research despite the publishing of positive results, and recommending proceeding with important research. The most recent information at this writing comes from Shulgin and Shulgin (1997), which covers a wide variety of interesting topics. Pertinent to this discussion are presentations on the nature and variety of psychedelic experiences and the growing appropriation of power by government to prescribe medical practice and scientific research (see, particularly, Part 2: Psychedelics and Personal Transformation, and Part 5: Drugs and Politics).

Although the articles discussed above contribute much important information, they still fall short in recognizing one of the most crucial aspects of psychedelic use. Most observers still lean toward the allopathic medical perception of drugs, in which the results are attributed to the particular action of the drug in the body. In the case of psychedelics, what transpires depends far more on the characteristics of the participant ingesting the drug and the circumstances of its use. It does not seem to be recognized generally that an individual can, with time and repetition, learn increasingly how to make more effective use of the opportunities psychedelics afford. It is possible to develop the characteristics of the trained user as previously described, when the mind can be held perfectly still so as to reveal other aspects of reality. With continued practice, the aspiring seeker increasingly learns how to focus the experience, learn trust, and develop motivation and courage for deeper exploration. This practice will yield deeper and deeper penetration into unknown areas of existence, with the possibility of bringing back ever new treasures.

I therefore hope that Buddhists and others will approach these substances with an open mind and, as a minimum, not stand in the way of efforts to learn more about them and the most appropriate ways of employing them.

> As you sit behind your desk, you may start to feel a little tingling sensation or a slight increase in awareness of things around you at the office, things that you didn't notice before. Words might appear brighter or sharper on the screen. And perhaps not so much changes around you but how you experience it changes quite a lot, you feel alive and quite present in your body. (Mishra 2020, p. 42)

This is an excerpt of an interview that Swasti Mishra (2020), one of the ChemicalYouth ethnographers, had with young professionals in Amsterdam who were self-experimenting with microdoses of lysergic acid, also known as LSD, and psilocybin, the active ingredient of "magic mushrooms." During the ChemicalYouth project, we observed that microdosing with psychedelics was emerging as a new trend among students and young professionals. Popular media such as *Forbes, Vice, Rolling Stone*, and *Marie Claire* published stories on this trend, with titles such as: "Micro-dosing: The Drug Habit Your Boss Is Gonna Love" (Dean 2017), "Interview With a Corporate Banker Who Microdosed His Way to the Top" (Fisher 2016), and "Can Very Small Doses of LSD Make You a Better Worker?" (Woods 2016).

O'Bryan Tear, a psychedelic researcher from the United Kingdom, defines microdosing as:

> taking a very small amount of LSD or magic mushrooms with the aim of boosting creativity, productivity or mood. So it does not give you a full recreational experience. It keeps you engaged and relatively sober, but it helps you work better and more productively". (BBC London News 2018)

Nina, one of Mishra's interlocutors, explains it as follows:

> It's not like taking a full dose....the tiny dose counteracts the "airy-fairy" psychedelic effect, and it

> lets you take advantage of the focus, the creative ways you can make new connections between different pieces of information, and even simply the good mood it puts you in. (Mishra 2018, p. 1)

In this chapter we explore this burgeoning practice of microdosing and three ways of gathering data to understand its effects: analyzing users' narratives, collaborating with users to aggregate user accounts, and organizing clinical experiments. In the first way, users' narratives show how they "do" microdosing, what they want to achieve by using these substances, and what they do to prevent or reduce harm. Mishra (2020), for example, examined the narratives of microdosers in Amsterdam, and followed their collaborative self-experiments over time. Some members of our team have also reviewed reports on microdosing in popular media and online, a form of "virtual ethnography" (see Krieg *et al*. 2017; Hupli *et al*. 2019). A second way of understanding the effects of microdosing is through the gathering of data that can aggregate users' experiences; such data has been generated through collaborations between researchers and users, and is reviewed here. Finally, a third way is through clinical trials that compare the effects of psychoactive substances with those of placebos. These studies use a "blinding" strategy, an administrative procedure that ensures that participants don't know if they are being given a psychoactive substance or pharmacologically inert one; in this way, researchers hope to unravel what the "real," that is material, effects of microdosing are.

In the conclusion, we reflect on the ways that the practical wisdom (Boothroyd and Lewis 2016) generated by young people in collaborative microdosing experiments is linked to larger scale surveys and trials that aim to generate scientific evidence on benefits and risks of microdosing. We outline the modes of "knowing" that these surveys and placebo-controlled studies produce, how they lead to re-articulations of chemicals efficacy and reflect on the ways it can be understood as regulation from below, a concept that we discussed in Chapter 2, and will further elaborate in Chapter 9, the concluding chapter.

A Brief History of Microdosing

People who engage in and study microdosing often mention Albert Hofmann, admired for his self-experiments with LSD. Hofmann was the first to synthesize the drug in 1938, when he worked for the pharmaceutical company Sandoz. He was exploring the alkaloids present in a fungus called ergot (used traditionally by midwives to induce labor). When synthesizing LSD he was interrupted in his work by "unusual sensations" due to ingesting a small amount accidently. He went home to lie down, reporting later that "in dreamlike state, with eyes closed. ... I perceived an uninterrupted stream of fantastic pictures, extraordinary shapes with intense, kaleidoscopic play of colors" (as quoted in Pollan 2019, p. 22). In his 1979 memoir *LSD: My Problem Child*, Hofmann describes a series of self-experiments that followed and includes excerpts from his lab journals, such as this one from April 4, 1943:

> 4/4/43. 16.20: 0.5cc of ½ promil aqueous solution of diethylamide tartrate orally = 0.25 mg tartate. Taken diluted with about 10 cc water. Tasteless. 17.00: Beginning of dizziness, feeling of anxiety, visual distortions, symptoms of paralysis, desire to laugh: Supplement of 4/12: Home by bicycle. From ca. 18:00-20.00 most severe crisis. (Hofmann 1979, p. 48)

Reflecting back on that day, he then comments that:

> Here the notes in my laboratory journal cease. I was able to write the last words with great effort. ... I had to struggle to speak intelligibly. I asked my laboratory assistant, who was informed of the self-experiment, to escort me home. We went by bicycle, no automobile being available because of wartime restrictions. (Hofmann 1979, p. 48)

Based on these self-experiments Hofmann (1979) concluded that LSD was a psychoactive substance with "extraordinary properties and potency" (p. 51). In 1947, Sandoz started marketing LSD (under the brand name Delysid) as a psychiatric drug.

James Fadiman was one of the first researchers to explore the effects of LSD on creativity, when he was still a graduate student at Stanford University in the 1960s. He designed an experiment to determine whether psychedelics could facilitate problem-solving of a technical nature. As Fadiman (2011) recalls:

> others had done work with artists - but we took on a different challenge. Could we use these materials and get people to work on highly technical problems. ... We began this really gorgeous study with senior research scientists from a number of companies. We told them that we'd assist them in their most pressing technological problems, particularly if they were really stuck. (p. 233)

The experiments conducted by Fadiman and others in this first wave of psychedelic research gave users structured guidance during their "trips," including preparation in the form of "flight instructions." These helped users "set" how they would navigate their experiences during the trip; for example, the "setting" of being in a safe place, accompanied by trip "sitters" helped ensure users that they would be supported if they experienced anxiety, fear, or adverse physical effects. The Spring Grove Group, which conducted research to find out if LSD could help alcoholic patients overcome their addictions, established the following setting: LSD treatment was done in a comfortable room, with a sofa, carpet, flowers, and a good sound system. Music was played throughout the session, and the trial subject was given eyeshades, allowing the patient to retreat into their imagination. A therapist guided the experience and helped subjects feel cared for, encouraging them to go with the flow of the drug-induced effects (Oram 2014).

Fadiman's research into the creative potential of LSD stopped in 1966, when the US Food and Drug Administration (FDA) declared LSD a scheduled drug. One of the main reasons for this declaration was the alleged "misuse" of the drug for recreational purposes by young people in the Sixties' counterculture. Despite not being able to complete the study, Fadiman concluded that the scientists who had participated in the experiment were pleased with the results: the drug had in fact helped them solve technical problems. One scientist even won a major scientific award (Fadiman 2011).

Indeed, early on in the history of LSD, the substance came to be heralded for its aid stimulating technological breakthroughs. John Markoff, a co-fellow at the Center for Advanced Study in the Behavioral Sciences at Stanford University, where I have written much of this book, suggests that the use of LSD to promote creativity had far-reaching consequences, stimulating the innovations that emerged from Silicon Valley in the 1960s and 1970s (see Markoff 2005). Steve Jobs, a dropout from college who experimented with drugs and was part of the youth counterculture in the 1960s, told him that, "taking LSD was one of the two or three most important things he had done in his life" (Markoff 2005, p. 21). Kary Mullis, who received a Nobel Prize for inventing the polymerase chain reaction (PCR), a revolutionary technique for multiplying tiny amounts of DNA for use in genetic research, similarly attributed his innovation to his LSD use. In an interview for a BBC documentary, he explained how psychedelic experiences helped him imagine how DNA works:

> I wasn't stoned on LSD at the time, but my mind had learnt how to get there. I could sit on the DNA molecules and watch the polymers go by. And I didn't feel dumb about it. I felt like that's just the way I think, I put myself in all different kinds of spots. And I learnt it partially, I would think, this is again my opinion, through psychedelic drugs. (Eagles 1997)

When Jobs and Mullis experimented with LSD, microdosing was not yet popular. In an online interview with Dutch microdosing enthusiasts, Fadiman explained "with a high dose, set and setting is as important as the drug" (Microdosing Netherlands 2019). In contrast, he says, "with micro-dosing, unless your outerworld is terrible, it does not seem to matter much ... Because its effect are so subtle, set and setting are far less important." The idea that LSD could be safely used at very low dosages is the innovating force behind microdosing.

Fadiman (2011) proposed a schedule of one day of microdosing, followed by two days off, and repeating the cycle starting on the fourth day. In the interview, Fadiman recalls that he proposed this schedule not as a standard practice, but as a tool for users to observe what microdosing did for them: "we wanted people to, on the third day, to experience how they feel without the substance, and reflect on the difference between 'on and off.'" He said that after one month of trying out this schedule, microdosers should be able to determine what works best for them. In *The Psychedelic Explorer's Guide*, Fadiman (2011) quotes a man named Charles, who used this schedule:

> The protocol I followed had me take a micro-dose one day, then carefully observe any ongoing or lingering effects the second day, and the give myself the third day completely off. By going slow, you give yourself a chance to really know, to really observe what is different, why it is different,

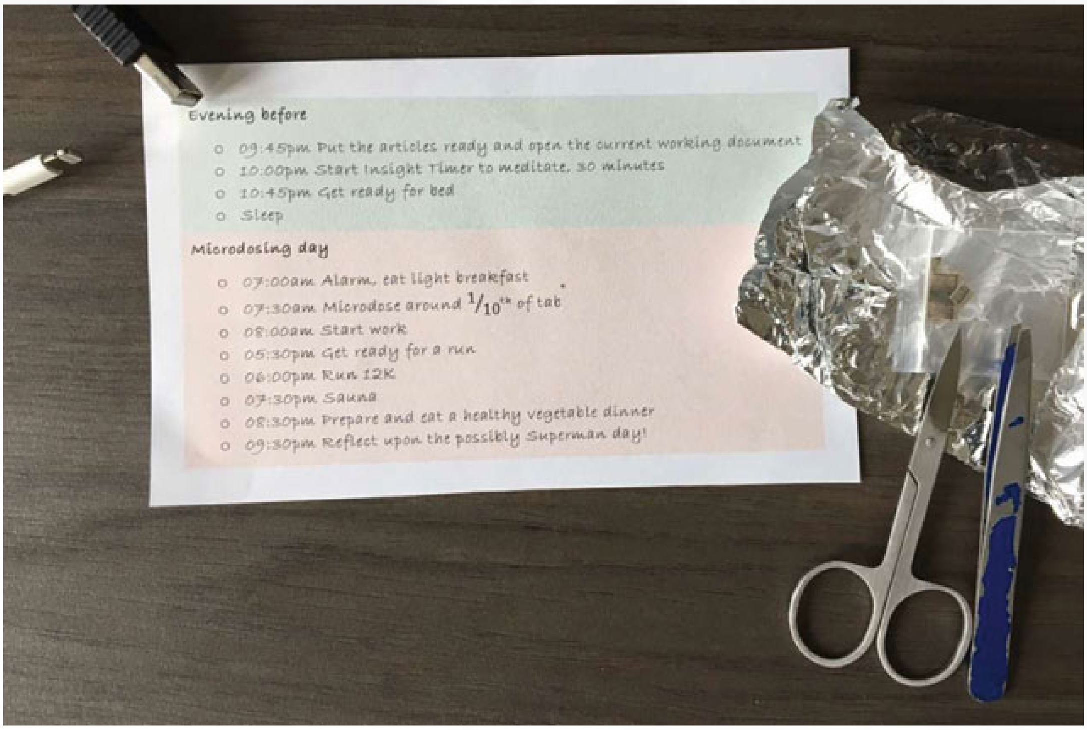
> and how you can best take advantage of it. ... I've found that I've had some brilliant outbursts (at least they seemed brilliant to me) with respect to both work and personal creative projects. (p. 200)

This guide also describes the experiences of a woman named Madeline, who attested to the creative potential of microdosing. A documentary maker from Manhattan, married with a four-year-old child, Madeline says she has to review 50 hours of film footage and "knit it together in a story arc," and that when microdosing she feels deeply connected to her work: "I barely come up for air for the next five hours because I am so sincerely enjoying what I'm doing" (Fadiman 2011, p. 202).

A similar narrative is reported in the popular women's magazine *Marie Claire*, which ran a story entitled "Why Power Women Are Micro-Dosing LSD at Work" (Malone 2016), in which a woman named Karen Smith, a 32-year-old who lives in Chicago, explains in detail how she made capsules and dosed psilocybin. Karen is enrolled in a data science graduate program after working for 10 years in a tech startup. Confronted with cold Midwest winters, and having quit cigarettes and marijuana, she was looking for something else to improve her mental well-being. Her husband had read about the beneficial effects of psilocybin on the forum-based website Reddit (which at the time had a forum on microdosing with over 9000 subscribers). The couple was offered some "magic" mushrooms - psilocybin containing-mushrooms - from a friend, which they ground up in a spice grinder. They bought empty capsules on Amazon, and packed them with the powder: 10 micrograms for Karen's husband and half that amount for Karen. They took a capsule every few days for four months. Karen started feeling better and became very efficient. In Karen's words, "It gives you fresh eyes ... for programming or figuring out algorithmic stuff. It made me really productive in a motivated way." An added benefit was that Karen got a lot of household chores done.

Microdosing Narratives

In the earlier use of LSD, preparation mattered - users were given "flight instructions" and trip sitters guided the experience. The stories that we reviewed suggest that microdosing has little to do with managing preparation or setting as a runway for an unpredictable flight. Instead, it involves material work, as presented in the story of Karen - preparing capsules, cutting blots, and weighing - as well as attending to schedules that ensure the productive insertion of microdosing into a day's schedule. Figure 8.1 provides an example of such a schedule from Mishra's fieldwork. Note how it includes timeslots for meditation, sleeping healthy eating, and a reflecting on the success of the day's work.



Evening before

- 09:45pm Put the articles ready and open the current working document
- 10:00pm Start Insight Timer to meditate. 30 minutes
- 10:45pm Get ready for bed
- Sleep

Microdosing day

- 07:00am Alarm, eat light breakfast
- 07:30am Microdose around 1/10th of tab
- 08:00am Start work
- 05:30pm Get ready for a run
- 06:00pm Run 12K
- 07:30pm Sauna
- 08:30pm Prepare and eat a healthy vegetable dinner
- 09:30pm Reflect upon the possibly Superman day!

Fig. 8.1 Inserting microdosing into a "Superman" day (Source Photo Swasti Mishra, November 2017, Amsterdam)

Trip sitters are not seen as necessary for microdosing. Instead users keep records of their own experiences themselves, many of them inspired by Albert Hoffman's laboratory notes. The narratives we examined suggest that microdosing had positive experience on users' moods and creativity, but that adverse events that interfere with the capacity to work could also occur. They also show that users compared the pros and cons of a range of substances (LSD, mushrooms, mescaline) for different tasks at hand. Finally, users commented on other medical benefits on microdosing, including their potential in the treatment of ADHD.

JingShu, one of Mishra's informants developed a scale to record the effects of microdosing over the course of 30 days, see Fig. 8.2. She divided effects into three categories: sexual, positive, and negative (each with their own summative indicator). She judiciously tracked various emotions and her work productivity, rating them on a scale of one to ten, and noting possible side effects.

Fig. 8.2 The 30-day observations of JingShu (Note Retrieved on May 24 2020 from https://microdosing.nl/i-microdosed-on-psilocybin-for-30-days-and-tracked-its-lasting-effects/. Source Photo from Mishra [2020, p. 37])

Her positive mood indicators included being present, peace, joy, love, passion, confidence, acceptance, courage, celebration, and gratitude. Over the course of the 30 days, her scores on positive affects became higher. She tells Mishra that she was impressed by the "non-stickiness" to both positive and negative events that occurred in her life (Mishra 2020, p. 37).

There are many such individual reports of experiences with microdosing on online forum-based sites such as Reddit (used by Karen) and drug-using focused sites like Erowid (2020). Erowid is an "experience vault," which is filled through decentralized user engagement (Liu 2012, p. 25) via voluntary submissions, and which is managed centrally by two experienced drug users (named "Earth" and "Fire") who screen and edit reports before they are published on the website. Our analysis of user reports on Erowid shows that most of the participants in the experience vault are young (average age 23) and male (86% of reports are from men; 14% from women).[1] While Erowid accepts reports on a wide range of drugs, the most commonly mentioned substances are mushrooms (*N* = 1715) and LSD (*N* = 1168). "Microdosing" was the most mentioned term in the LSD reports, which attests to the popularity of this practice.

An example of such a report is entitled "Psychedelic Microdosing: A Surprising ADHD Fix" (Erowid 2020). This report concerns 1P-LSD, a synthetic modification of LSD. "Designer drugs" such as 1P-LSD have emerged in this underground drug-use culture as a way of avoiding drug regulations that have defined LSD itself as illegal. The user who wrote up the experiences with 1P-LSD does not self-declare his/her age or sex, but does give his/her weight (60 kg) and the dose used (6 µg), while proposing a dosage scheme that consist of 1/16 rather than 1/10 of the regular dosage, and reports that he/she did not experience any side effects:

> I had been trying out magic mushrooms (or rather magic truffles) with... "interesting" results. But they are of tremendously repellent taste, and the reliable occurrence of nausea makes them unfit for daily utilisation. It was only then that I found out about 1P-LSD, a novel lysergamide that had entered the market only this very year and, being not yet statutory regulated, was being sold legally across Europe (and in some countries, still is). After reading up on it, I came to the conclusion that, judging by the majority of reports out on the interwebs, its biochemical response was indiscernible from that of its famous twin, LSD-25 [The drug that Sandoz branded as Delysid, which was taken off the market in 1966]. Excitedly, I ordered a sample from a research alchemist.
>
> A period of experimentation followed, and I had some profound experiences with this substance ... the real revelation was the unexpected attenuation of my ADHD symptoms. Not only was I able to focus much better, both at work and university. Mood swings and impulsive behaviour basically vanished. During conversations, it has become easy for me to subdue my urge to interrupt, instead patiently listening to the other person and replying in a concise and considerate manner.
>
> Addendum: I have shared my find in my local ADHD support group. Several others have reported back with comments such as "helpful effects" "better concentration and general condition," "less thought racing," "less irritable" etc. One group member, who happens to be an alcoholic, happily recounted that each day he is microdosing, the urge to open yet another beer vanishes, and he will not even finish his first one.
>
> Addendum 2: To better assess the effects of 1P-LSD, I reverted back to Ritalin for a day while working on a very concentration-demanding job. In direct comparison, inattentivity is decreased to a similar extent with 20mg Ritalin as is with 6mcg 1P-LSD. In my opinion though, Ritalin does not feel quite natural, while the LSD does. It is just a more pleasing remedy.

This user turned to a new chemical (1P-LSD) that was similar to LSD, reporting not only on its effects but also on their research process; this suggests that, like many reporters on Erowid, this user is an experienced "psychonaut" (a user who tries out new designer drugs on a regular basis to examine the altered states of consciousness that the substances generate, see Berning and Hardon [2016] and Langlitz [2012]). This user was interested in trying out microdosing to be more creative and productive, as well as in doing research and connecting to others to share their experiences, especially with fellow ADHD sufferers.

Video reports of experiences with microdosing are also posted on YouTube, a platform that makes it easier to share the material aspects of "doing" microdosing and "real time" effects. Aleksi Hupli and Moritz Berning, who both participated in the ChemicalYouth project as ethnographers, used the YouTube Data Tool developed by the Digital Methods Initiative of the University of Amsterdam to explore these visual demonstrations of users' techniques (Hupli *et al*. 2019). The search, conducted in June 2016, resulted in 115 videos - six of which accounted for 92% of approximately 1 million total views. Subsequent extractions in November 2017 ($N = 351$) and October 2018 ($N = 447$) revealed a surge in video postings.

One of the two most popular videos, *Your Mate Tom*, presents Tom who consumes mushrooms in front of his camera, which the video declares are "props" (perhaps to avoid legal repercussions). Fifteen minutes after consumption Tom reports not feeling high but instead calm, despite his heart rate being slightly elevated. He says he feels "a bit chill, a bit calm, like I had one little tiny drag of a joint" (as quoted in Hupli *et al*. 2019, p. 133). He also tells his audience about an adverse event that happened when he took "three little mushrooms" on his way to the university to study for an exam and he "started to feel a bit funny," anxious and having mild visual distortions. Attesting to a need for cautious dosing, he says "that's what I get for not actually getting scales and measuring it. That's what I get for just estimating" (quoted in Hupli *et al*. 2019, p. 133).

Another highly viewed video, posted by PsychedSubstance, also calls for cautious dosing, suggesting that a person should first take half of the threshold amount; then, if they don't feel anything, slowly increase the amount by 25-50% until they "hit 1.5 of the threshold" (Hupli *et al*. 2019, p. 133). The video further recommends using a test kit, with a link to purchase it in the video description, to verify the purity of LSD. PsychedSubstance recommends that dosing every other day would be ideal,[2] since the body builds a tolerance to classical psychedelics immediately.

PsychedSubstance also compares the effects of different psychedelic substances, saying: "I can speak from personal experience being on mescaline microdose right now that it feels extremely similar to being on LSD microdose" (quoted in Hupli *et al*. 2019, p. 134). He tells the audience that his thoughts run a lot smoother on mescaline than on LSD, and that he experiences more auditory enhancement when using mescaline; when using LSD, in contrast, he experiences more visual enhancement.

Aggregating Experiences

The online platforms where users exchange experiences are convenient virtual spaces for academic researchers to engage with users and learn from their experiences. Efforts to aggregate user experiences confirm the observations of individual users: microdosing enhances creativity and elevates moods. But, the studies also point to adverse effects, and contra-indications for use.

Johnstad (2018), from the University of Bergen, engaged online users in a qualitative microdosing study. He posted an online thread that, after describing the purpose of the study, asked for input. He then approached users who reported on their microdosing practices via the private message function. Through open-ended, qualitative interviews he accumulated a great deal of data. Twenty-one respondents (all male, average age 30) agreed to be interviewed. Johnstad (2018) reports that his respondents reported positive health benefits, including feeling less depressed and anxious, though a few respondents experienced no effects at all and therefore stopped doing in. The participants in Johnstad's study, like many of the users referred to above, were interested in comparative efficacy. Some reflected on differences between LSD and mushrooms, as expressed by one informant: "LSD is just more practical for work and play, bounding energy and target mentality. Mushroom microdoses are more of a personal and 'fresh' interaction with the universe" (Johnstad 2018, p. 46). Despite general agreement on the lack of intoxication produced by microdoses, some respondents did report adverse events. They attributed these to taking a slightly higher dose, referred to as a "mini-dose," or to timing the use incorrectly, which resulted in tripping and having difficulty performing the tasks at hand. As one of Johnstad's (2018) respondents reported:

I was feeling very tired and had a martial arts class to attend for the first time, so I didn't want to make a bad impression. This was my second time microdosing [mu]shrooms, and I dosed around 0.25-0.35 gram a few hours before in an attempt to peak well before the class and still just be stimulated and in a good positive mood for it. This backfired massively as I had a large meal around the time of dosing and it really kicked in once I got to the class. I found it very hard to follow instructions. (pp. 46-47)

Others reported insomnia after microdosing late in the day, and some also said that, after microdosing for a while, benefits faded and mental health conditions were exacerbated.

Fadiman and Korb (2019a, b) encouraged people who contacted them for advice to send reports of their experiences, using a Google form and a dedicated website (microdosingpsychedelics.com). They describe this work as "citizen science, a social agreement where researchers enlist those members of the public with an interest in a particular topic or issue to upload their own observations or local experiments into an unrestricted database" (Fadiman and Korb 2019a, p. 321). In citizen science, participants are not study subjects, but collaborators. The collaboration involved the researchers providing information on what they knew about the practice, and participants filling in Google forms, which, in addition to daily mood check-ins, included a modified version of the Positive and Negative Affect Scale (PANAS; see also Watson and Clark 1988). Over 18 months, 4000 people wrote in asking for information, and 843 responded to the request to fill in a Google form.[3]

Thus, the majority of people who were asked to join the study did not do so. This may have happened for many reasons: perhaps they decided not to microdose. Or perhaps they did try it, but stopped because it didn't work for them. Or they liked the effects, but didn't want to spend time participating. Fadiman and Korb (2019a) note that they had discouraged volunteers who appeared disorganized, were experiencing a bad period in life, as well as those with a history of psychosis, acknowledging that their findings were, therefore, not necessarily representative of the population of users:

> It is entirely possible that a sizeable percentage of the general population, were they to microdose, would experience no discernable effects. Another significant percentage might have a sufficiently negative experience such that they would not be inclined to continue or contribute a research report. (Fadiman and Korb 2019a, p. 322)

- Attentive: paying close attention
- Focused: able to direct specific attention
- Depressed: generally unhappy or despondent
- Clear: free of unpleasantness or confusion
- Guilty: feeling regret for doing something wrong
- Proud: having a sense of achievement
- Irritable: feeling easily annoyed
- Strong: feeling able to cope with difficulties
- Ashamed: feeling shame for doing something wrong or foolish
- Interested: wanting to be involved in something
- Jittery: feeling agitated and edgy

Note that the list includes positive and negative affects in random order. Using this scale, Fadiman and Korb (2019b) found that 52.5% of the people who participated in the study experienced a relative improvement in the positive affects, and 31% experienced a decrease in negative affects. Overall, they reported elevated moods, and they found that microdosing was helpful for their productivity. A number of respondents said that they had been more creative, which they underscored by sending some of the art and music that they had crafted (Fadiman and Korb 2019b, p. 121). Interestingly in this large-scale survey, a substantial number of participants preferred microdosing to the use of ADHD drugs such as Ritalin for improving their productivity and focus, echoing the reports on Erowid (see above).[4]

Fadiman and Korb's "citizen science" approach aims not only at demonstrating benefits but also making microdosing safer. They write: "we tried to give the best and safest current information as we went along in these aggregated self-reports" (Fadiman and Korb 2019a, p. 327). Based on the data collected in their study, they advised lowering the suggested dose from 1/10 to 1/20 of a regular dose, warned that people with a red-green colorblindness could experience visual distortions for a number of days after discontinuing use, and warned of interactions with medications, such as lithium. They also called for more research: "The next steps are for research institutions to turn our search into research, establish safe methods and protocols, and scientifically verify or invalidate the claims we see in our inboxes and hypotheses we and others generate" (Fadiman and Korb 2019a, p. 322).

Academic researchers have been taking on this challenge in different ways. Here we present the findings from two such studies, one using an online questionnaire - an approach similar to that of Fadiman and Korb - and another extracting data from a real life microdosing event.

In 2018, the University of Maastricht's Department of Neuropsychology and Psychopharmacology conducted an online survey focusing on the benefits of microdosing on creativity, cognitive flexibility, and well-being (Hutten *et al*. 2019). Their online questionnaire was advertised to microdosers through online fora. The researchers received responses from 1116 respondents, largely young and male (18 years and older; 84% men; 14% women), of whom 80% were currently microdosing. The researchers report that performance enhancement was the most important stated purpose for microdosing. Enhanced creativity and enhanced mood were the most commonly reported positive effects. Psilocybin and LSD were the most used substance; dosing schedules varied. Around one-fifth of the respondents said that they had stopped microdosing completely, and one-third said they had stopped using at least one kind of psychedelic substance. Reasons given for stopping included doubt about efficacy and negative physical and psychological experiences (these are not specified in the study).

Researchers from the Brain and Cognition Institute of Leiden University, the Netherlands, in collaboration with the Psychedelic Society of the Netherlands, did a natural experiment at a microdosing event to assess the extent to which creativity is enhanced through microdosing (Prochazkova *et al*. 2018). Participants were asked to complete tasks to assess their creativity-related problem-solving skills, once before taking a microdose and once around 1.5 hours after taking a microdose. This timeframe was chosen because self-reports in the Erowid archive of user experiences suggest that effects of mushrooms peak between 30 and 90 minutes of use.

Out of 80 attendees at the event, 38 volunteered to participate in the experiment (23 men and 15 women, average age 31). In this experiment the amount of mushrooms was adjusted to their weight. Attendees with low body weight were given 0.22 grams, those with average weight 0.33 grams, and those with high body weight 0.44 grams, but participants were also free to adjust. The dosage was calculated based on the definition of microdosing as 1/10 of a recreational dose. The researchers also analyzed the presence of psychedelic alkaloids in the mushrooms, such as psilocybin.

The researchers report an increase in divergent idea generation, flexibility, and originality scores. The tests used included the Picture Concept Task, which measures visual creativity; it involves finding an association between several images. It also included the Alternative Uses Task, which is used to measure the possible uses of an object. The researchers write that the benefit of this study design is that it is done in a natural setting, but the disadvantage is that use is less controlled than in a laboratory, and that there is no control group. As a result, they do not know if the improved scores on creativity after using mushrooms are due to other factors, such as the learning that took place in the pre-mushroom-use tests, or the expectation that mushrooms increase creativity. Moreover, a positive mood and thrill of being part of the collective experiment could have influenced the test results. These researchers from the Brain and Cognition Institute of Leiden University were concerned with the "confounding" influence of users' expectations, a concern that set them apart from the first wave of psychedelic researchers, who explicitly aimed to create a positive expectation in order to enhance the effects of the psychedelic substances. In their scientific report on the experiment, the researchers emphasize that "future studies should seek to validate our findings using a lab-based randomized double-blind placebo-controlled experimental design" (Prochazkova *et al*. 2018, pp. 3409-3410).

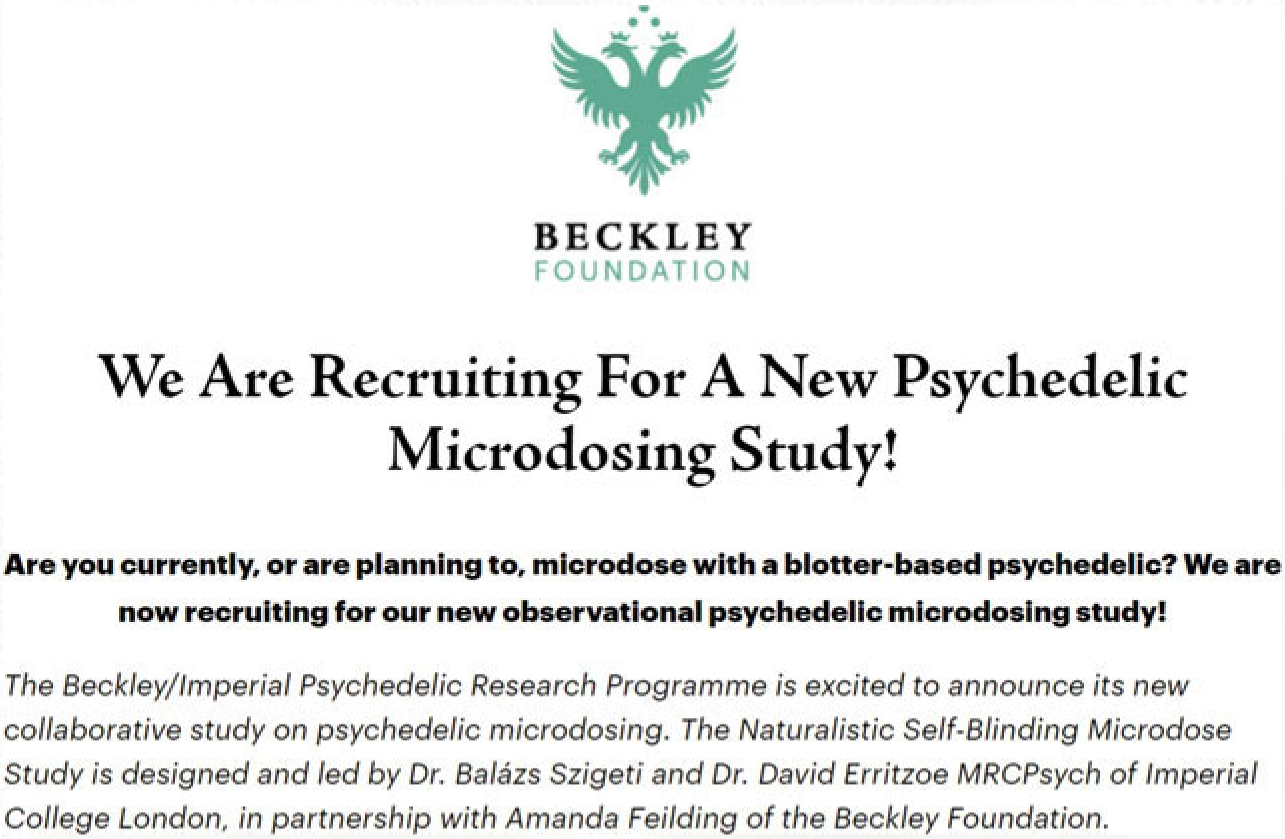
Collaborative Trials

In the hybrid communities of users and academic researchers that participate in such online studies, there is an emerging call to study if the effects of microdosing are "real" through placebo-controlled controlled trials. A research group at the University of Maastricht has conducted a critical review of existing "evidence," finding that future studies need to examine whether there is an "expectation" effect (Kuypers *et al*. 2019). While microdosing is associated with positive effects in existing observational studies, these studies are of users who take the substances for the express purpose of increasing performance and creativity, and thus may expect positive effects. The researchers recommend "rigorous placebo controlled clinical studies with different low doses of the drug to determine whether there is any evidence for the claims being made by microdosers" (Kuypers *et al*. 2019, p. 1046). They also stress that, at the time their review was published, only one study had followed a double-blind, placebo-controlled protocol to look at the effects of microdosing LSD (see Yanakieva *et al*. 2019). This relatively small study (only 48 subjects were enrolled) reported a limited effect: a delay in time perception after the administration of single microdoses of LSD.

The UK-based Beckley Foundation, the founder of which openly admits to having benefited from experiences with LSD in the 1960s, is committed to supporting researchers who seek to generate more reliable evidence. On its website the foundation states:

> Although many underground adherents attribute a variety of psychological and physical benefits to microdosing, including enhanced mood, focus, and cognition, or even reduced pain, there is a dearth of reliable evidence of the benefits - or indeed any potential health effects - of the practice. (Beckley Foundation 2017)

Together with researchers from Imperial College in London, the Beckley Foundation is engaging users in the production of such reliable evidence. At the time of writing this book, the study was recruiting participants who already engaged in microdosing, or who were about to participate in a naturalistic *self -blinding* study, which would allow for the collection of more reliable evidence (see Fig. 8.3, the recruitment advertisement).



BECKLEY
FOUNDATION

We Are Recruiting For A New Psychedelic Microdosing Study!

Are you currently, or are planning to, microdose with a blotter-based psychedelic? We are now recruiting for our new observational psychedelic microdosing study!

The Beckley/Imperial Psychedelic Research Programme is excited to announce its new collaborative study on psychedelic microdosing. The Naturalistic Self-Blinding Microdose Study is designed and led by Dr. Balázs Szigeti and Dr. David Erritzoe MRCPsych of Imperial College London, in partnership with Amanda Feilding of the Beckley Foundation.

Fig. 8.3 Recruitment advertisement on the Beckley Foundation website (Beckley Foundation 2017)

The website for the study contains a guide on how to carefully prepare microdoses and make capsules, which are either a placebo or a microdose, and how to pair the capsules up with QR codes in envelopes that are then randomly allocated over testing days, see Fig. 8.4.

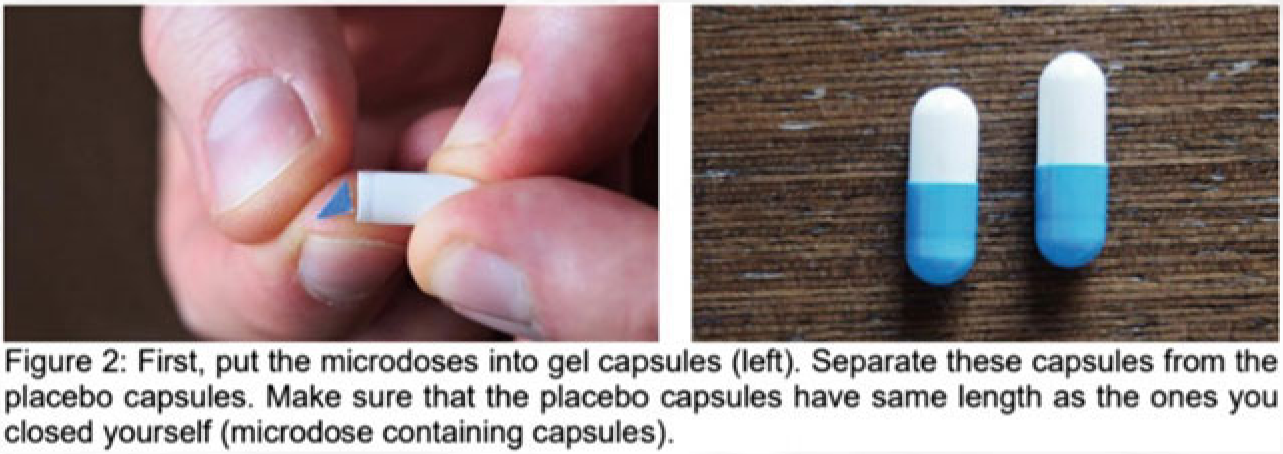


Figure 2: First, put the microdoses into gel capsules (left). Separate these capsules from the placebo capsules. Make sure that the placebo capsules have same length as the ones you closed yourself (microdose containing capsules).

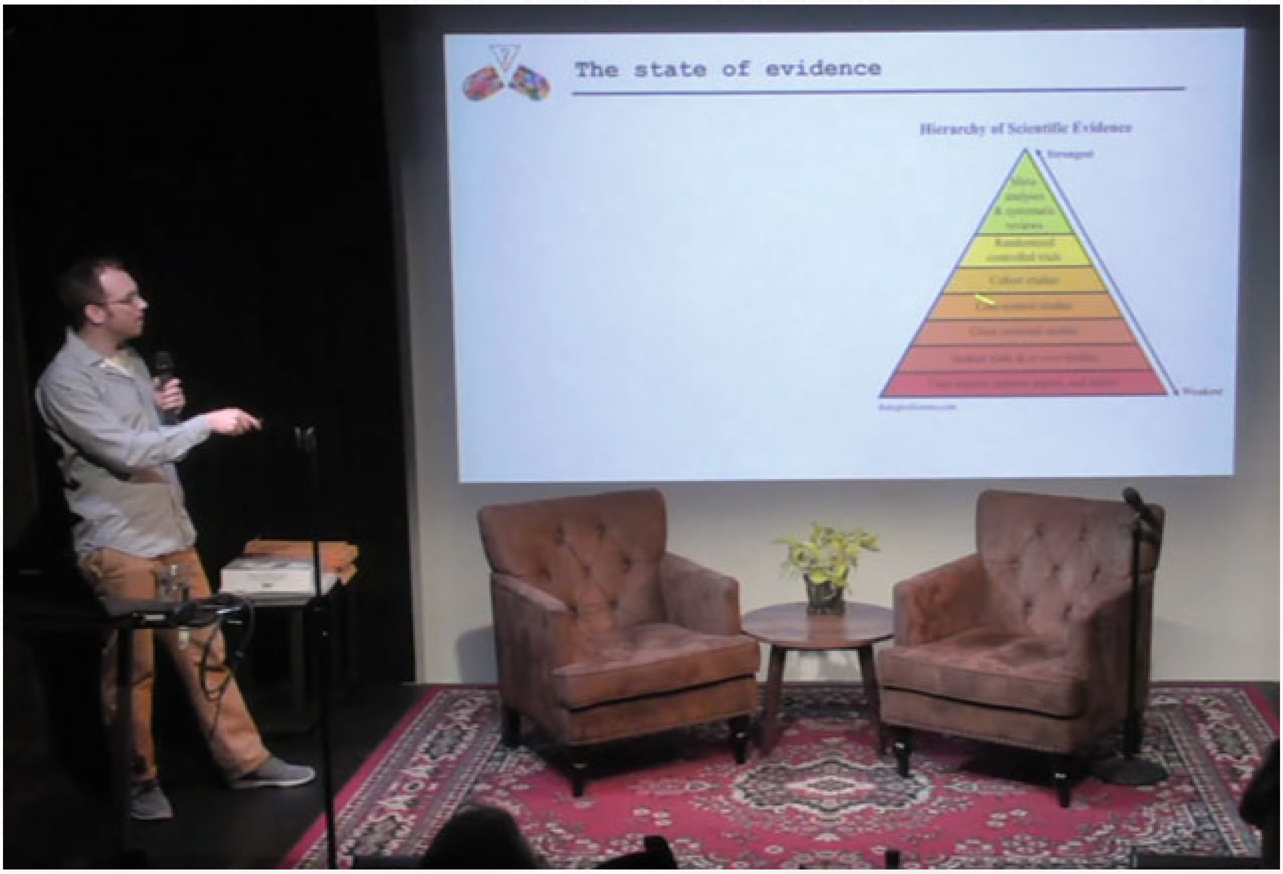
Fig. 8.4 The placebo and microdose capsules that users are expected to prepare themselves (*Source* Screenshot from the self-blinding manual [Imperial College London 2020])

Szigeti, one of the Imperial College researchers explains why "blinding" is necessary in an informational YouTube video entitled "Is Microdosing Placebo? The Self-Blinding Study" (b1987307 2019), which the Beckley Foundation links to on its website. He cites a pyramid of evidence, pointing to randomized controlled trials at the top of the pyramid and individual case reports at the bottom (Fig. 8.5).

Szigeti argues that, at present, "There is no evidence for microdosing, but also no evidence against it." Why don't the many user stories and results of observational studies count as evidence? He argues that the observational studies that have been done so far don't provide evidence because they do not account for the expectation effect. A self-blinding placebo-controlled study can provide more rigorous evidence, he suggests.



The state of evidence
Hierarchy of Scientific Evidence
Randomized controlled trials
Cohort studies

Fig. 8.5 Szigeti arguing for the need for more reliable evidence (b1987307 2019) (Note the comfortable, home-like surroundings in which Szigeti presents the state of the evidence. *Source* Screenshot by Anita Hardon, January 2020, the Netherlands)

As we mentioned above, in the past, psychedelic researchers sought to cultivate a positive effect by setting expectations. The "flight instructions" developed by these early researchers were designed to produce specific kinds of positive effects, including capacities to problem solve as well as therapeutic efficacies. Preparing for such desired effects was considered as important as the consumption of the substance. Today, those engaged in microdosing, in contrast, appear intent on measuring the materials effects of LSD and mushrooms, purified from the influences of set and setting. Why is this so? To some extent, we can attribute self-blinding trials to the prohibition of psychedelics. Microdosing would be much easier if the substances used were studied, regulated, and allowed on the market. "Reliable" evidence from randomized controlled trials could help producers file for regulatory approval of microdoses of LSD and psilocybin for specific indications, such as ADHD.

Hubs of Concern and Collaboration

Toward the end of the ChemicalYouth project, I attended a talk on microdosing at the Trimbos Institute, a Dutch institute for mental health. Trimbos runs the Dutch Drugs Information and Monitoring Services (DIMS), which has observed an increase in microdosing of psychedelics because users increasingly come to DIMS to have their LSD tested. In the Netherlands, microdosers are in the luxurious position of living in a country where the use and sale of magic mushrooms is legal, and the quality of LSD can be tested through one of the 31 drug testing sites in the country (see also Chapter 2).

The speaker was a moderator of microdosing.nl, an online forum for Dutch microdosing enthusiasts. He presented a protocol similar to the cautionary approach proposed in the PsychedSubstance video, advising users to start with a very low dose and then gradually increase it to find one's "sweet spot." Following this session, I explored the Dutch website of microdosing.nl and found the very interesting interview between two young moderators and Fadiman, mentioned earlier in this chapter (Microdosing Netherlands 2019). In this interview, Fadiman emphasizes that online surveys of experiences are important, because they provide insights into what the substances can do. He also notes that scientists want to have clear biological endpoints;

scientists like stuff that they can measure. But, he asks, can clinical trials be designed to measure the effects of microdosing? How do you measure having a good day or a productive one? What constitutes a good day will differ from person to person. People report working well, eating healthily, and even forgetting that they took a pill. How to measure such a range of effects?

The Dutch moderators asked Fadiman to reflect on users' embrace of microdosing to enhance their moods, creativity, and productivity. They ask: "Wouldn't it be better to have a good day without a supplement?" Fadiman responds: "The answer is: do you really need an apple? Or is there any point in having wine with your meal?" He points out that as far as is known today microdosing is safe. So why not take it? The Dutch moderator ends the discussion by comparing microdosing to cycling: "We all do it and don't want to live without it. We know there can be a danger, you assess the risk, you watch the traffic."

How popular microdosing had become was clear at the 2017 NextWeb conference for Tech innovators and start-ups, which was held in Amsterdam with 15,000 attendees from all over the world. The program included Paul Austin one of the leaders of the Third Wave - an online hub for responsible psychedelic use. Austin told the audience that microdosing can help business leaders excel, because it allows them to be creative, adaptable, patient and present: "It's about this sense of being in the zone. In the zone, present, in the moment. Microdosing psychedelics can do this, sex does this, extreme sports do this, being really engaged and focused and dedicated on a project that you really love does this" (Aronov 2019, p. 711).

In contrast, there is the more cautious conclusion of JingShu, interviewed by Mishra. More doubtful on the need for microdosing after trying it out for 30 days, Jingshu says, "I was quite skeptical of the mentality of optimization in this fast-paced, competitive world: what are we optimizing ourselves for?" (quoted in Mishra 2020, p. 37).

In Conclusion

This chapter describes how users and researchers have been exploring the effects of microdosing in three different ways, each of which generates different ways of "knowing" the substances. First, user narratives focus on a plurality of creativity, focus, and productivity-enhancing effects of these chemicals. They describe how users incorporate microdosing in daily schedules, attend to diets, and adjust dosages. Moreover, we observed users comparing the effects of different psychedelic substances, aiming to tailor the choice of substance to the task at hand. The online peer-to-peer sharing of experiences, support and co-creation of knowledge "constitutes an emergent and constantly evolving form of practical wisdom" (Boothroyd and Lewis 2016, p. 293). This chapter shows how, in a second way of exploring effects, researchers build on this practical wisdom in designing studies that seek to aggregate user experiences. These observational studies seek user collaboration through online fora and real life events to augment understanding of how the effects of microdosing are moderated by underlying conditions (such as anxiety and colorblindness), and interactions with other medicines. These researchers do not see this as conclusive evidence, but rather point to issues that need to be explored further: To what extent do the positive experiences just reflect placebo responses? Most users stop after a while - so what do we know about long-term effects? Does tolerance build after microdosing for a long time? The third way to study the effects of microdosing are randomized controlled trials. These aim to test if the effects of microdosing are "real," that is caused by the psychoactive substance used in the microdosing practice. The evidence generated by such studies depends on the "endpoints" chosen and the biological markers used.

While the first two ways of exploring microdosing are aimed at "improving" effects by trying different microdosing schedules, dosages and diets, and aggregating experiences through observations, the third way of doing research is aimed at "proving" effects through trials (Mol 2006). Improving through tinkering allows users to adjust dosages, experiment with diets as adjuncts to the treatment, and determine how best to embed microdosing in daily routines (Mol and Hardon 2020). It also allows users to adjust the microdosing regime to the work at hand: to perform during a job interview a different kind of microdosing is called for, than when aiming to solve a technical puzzle in the privacy of one's study.

Such tinkering is not possible in clinical trials which are designed to "prove" the effects of standardized treatments using pre-defined endpoints, while filtering out any "expectation" effects. Proving through clinical trials, however, has as advantage that if sufficient experiments have been done, the evidence can be submitted for review to the food and drug authority.

Though it is too early to tell, randomized controlled trials could prove that microdosing does indeed have specific beneficial material effects. But this does not mean that microdoses of LSD or psilocybin could immediately enter the market. Food and drug authorities will demand results from large-scale "phase 3" trials, which are expensive, and may be reluctant to review new indications for psychedelics, because these drugs were used recreationally in large doses in the past, resulting in its scheduling in the 1960s.

However, it can be done. The Multidisciplinary Association for Psychedelic Studies, a nonprofit organization based in Santa Cruz, California, received the green light from the US FDA to do phase 3 placebo-controlled trials of MDMA (a drugs which has also been used for recreational purposes) for the treatment of post-traumatic stress disorder, and in 2019 the association published positive results from these trials, which led to FDA approval to expand access to this treatment (Mithoefer *et al*. 2019).

Could researchers win such approval for the use of microdoses of LSD and/or psilocybin for creativity and productivity? It seems unlikely, because here the indications are not medical. But let's assume that large-scale trials were done, and that, as was the case for MDMA, the results were positive. Hypothetically, this could convince authorities that microdosing is effective, and that microdoses of LSD and/or psilocybin can be used safely. If this happens, the substances will be re-"informed," changing from illegal recreational substances to medicines for cognitive enhancement. We expect that, if this happens, microdoses would be incorporated into the vibrant online market for drugs used to enhance cognition, referred to as "nootropics." Web-based shops sell supplements such as "Rise," a daily nootropic for memory, and Sprint, a nootropic for energy and focus. HVMN (pronounced 'human'), the company that makes Rise and Sprint, "believes that the human system can be quantified, optimized and upgraded" (Angel 2018, p. 67). Given the wide range of positive user experiences, companies like this one are likely to be interested in adding microdoses to their product lines. If this happened, Karen and other users would not have to go through the material work of making capsules, weighing chemicals, and testing for purity. They could simply buy their preferred substance online.

That the products would be available in standardized forms, with precise advice on how to take it, does not mean that tinkering would end. Whether LSD and psilocybin are approved or not, users will continue to tinker with diets, dosages and schedules relying on shared practical wisdom online, which has been augmented with insights from surveys and trials. The chapter shows how throughout the different kinds of collaborative experimentation and every day tinkering the properties of LSD and psilocybin evolve - new benefits emerge, dosages are adjusted, and cautionary tales shared. The practice is fluid, and ways of knowing are always emergent (Hardon and Sanabria 2017; Mol and Hardon 2020). The peer-to-peer sharing, and collaborations with researchers make up a dynamic form of regulation from below, which acknowledges the experiences of users, and helps refine the practice so as to maximize a wide range of benefits, and prevent harm.

ChemicalYouth Ethnographers

Swasti Mishra is an anthropologist with interest in the intersections of health, drugs, biomedicine, and society. She completed her PhD under the ChemicalYouth project, at the University of Amsterdam. Her doctoral research focused on the generation and circulation of knowledge about psychedelic drugs, including from clinical trials, psychiatric practices, and public health centers, as well as their non-medical use in office spaces or festival venues, primarily situated in the United States and the Netherlands. She is currently part of a research project on the assessment of public health emergency preparedness across the European Union Framework contract with European Centre for Disease Prevention and Control (Fig. 8.6).

Fig. 8.6 Swasti Mishra

Lisa Krieg studied cultural anthropology at the University of Heidelberg, and defended her PhD on social memory in Germany in 2016 at Utrecht University. She joined the ChemicalYouth team as a virtual ethnographer, and conducted research collaboratively with other team members on digital archives of drug experience reports, working on platforms such as Erowid and Wikipedia. Currently, she works at the University of Bonn on human-nature-technology relations (Fig. 8.7).

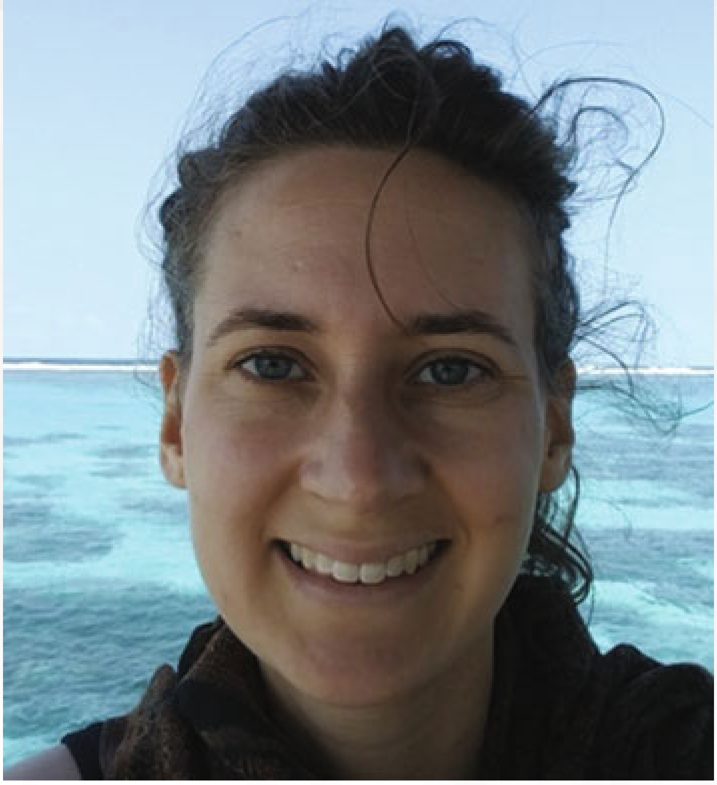


Fig. 8.7 Lisa Krieg

Moritz Berning focused on mixing classical and virtual ethnographic research, trying to balance the limitations that come with each approach. For the ChemicalYouth project, he explored how risk is approached and managed with regard to old and new psychoactive substances. These included situational practices at festivals or clubs, as well as refined social mechanisms of testing substances in virtual spaces (Fig. 8.8).

Fig. 8.8 Moritz Berning

Aleksi Hupli has been trained as a medical anthropologist by the University of Amsterdam (2013) and as a sociologist by the University of Helsinki (2014). He is currently finishing his PhD in sociology at the University of Tampere focusing on cognitive enhancement drug use among student populations. He has also coordinated the Global Drug Survey in Finland since 2017, is a board member of the Finnish Association for Humane Drug Policy and Legalize NL, serves as the president of the Amsterdam Society of Medical Social Scientists, and is a member of the Finnish Bioethics Institute (Fig. 8.9).

Fig. 8.9 Aleksi Hupli

Notes

1. We developed an interactive website (https://chemicalyouth.org/visualising-erowid/) that provides insights into more than 9480 users' reports.
2. This dosing rationale differs from that proposed by Fadiman, who suggested that the second day be microdose-free, in order to experience what it is like to not be affected by the substance. Fadiman's advice was aimed at supporting research into the effects of microdosing, by contrasting substance-free days with those affected by the microdose.
3. Three hundred and sixty-six people sent in one day of data; 137 sent in data for more than one day and less than a week; 340 sent in data for longer than one week.
4. The advantage of microdosing LSD over ADHD drugs was also discussed by Mishra's (2020) interlocutors, who said that on LSD they didn't experience "the comedown of other stuff "; they also pointed to cost advantages, arguing that in the Netherlands microdosing was "even cheaper in the long run, though it depends on how you source it of course. An LSD tab cut into eight pieces is just five euros divided by eight, while Ritalin off-label you get for five euros per pill" (p. 42).

Abstract

Human creativity is difficult to define and measure, but it is undoubtedly an important cognitive process. This makes it an interesting challenge for modern neuroscientific exploration - especially given the current interest in developing cognitive enhancers for commercial and clinical uses. There are similarities between the typical traits of creative people and the subjective psychological characteristics of the psychedelic (hallucinogenic) drug experience. This phenomenon was studied in a number of small trials and case studies in the 1960s. Results were inconclusive, and the quality of these studies - by modern research standards - was merely anecdotal. Nevertheless, with today's current renaissance in psychedelic drug research and the growing interest in cognitive enhancing drugs, now may be the time to re-visit these studies with contemporary research methods.

Key words psychedelic; creativity; LSD

Introduction

The psychedelic drugs and their related cousins are enjoying a renaissance in medical research. In the spirit of medicine's first foray into the possible uses for these drugs in the 1950s and 1960s, the majority of contemporary studies have focused on their potential clinical applications. However, just like some of the earliest scientific studies with lysergic acid diethylamide (LSD), modern research may also re-open avenues for experiments with less immediately obvious clinical applications that may nevertheless shed light on what these unique substances can teach us about the brain. One such area worthy of re-visiting with modern research is the role that psychedelic drugs play in the realm of creativity. To propose such a project one must first briefly describe some of the challenges that are faced when studying the concept of creativity - such as how creativity is defined and measured.

What is creativity?

The word create derives from the Latin *creatus*, 'to have grown'; defined as a mental process involving the generation of new ideas or concepts or new associations between existing ideas or concepts. The ancient Greeks talked about creativity in the context of poetry 'bringing new life into the world', and ancient Rome expanded this further to encompass the creativity of art and architecture. Creativity may be seen from the perspective of theology, philosophy and psychology - but is most frequently applied from the point of view of art and design - and more recently in the commercial industry of advertising - where it is seen as an essential tool in stimulating product development and marketing strategy.

Formal attempts at defining creativity

In his book The Art of Thought (1926), Graham Wallas described five stages of the creative process, from *preparation*, *incubation*, *intimation* and *illumination* through to *verification*, and considered creativity to be an evolutionary process allowing humans to adapt to their changing environments. The American psychologist Guilford (1966) made the distinction between convergent and divergent thinking processes, whereby the latter involves creative generation of multiple answers to a set problem opposed to aiming for a single, correct solution to a problem.

Neurobiology of creativity

The well-documented 'left brain-right brain' model of brain function often polarises an individual's skills as artistic at the expense of language and mathematics. However, using evidence from lesion analysis, functional imaging and drug studies, the Harvard neurologist Alice Flaherty (2005) challenges this popularly held belief and describes a *three*-factor anatomical model of creativity that focuses on interactions between the temporal lobes, frontal lobes and limbic system - mediated by dopamine activity.

It is recognised that creative thinking requires more than just a general intelligence and specific knowledge, but also the ability to develop alternative solutions to a single question - or divergent thinking (Balzac, 2006). Heilman, *et al*. (2003) proposed that creative innovation requires the co-activation and communication between regions of the brain that ordinarily are not strongly connected. Heilman suggests that highly creative individuals are able to store extensive specialised knowledge in their temporoparietal cortex, be capable of divergent thinking mediated by the frontal lobe and, crucially, be able to modulate the activity of the locus coeruleus (which fires in response to novel stimuli) via the norepinephrine system, 'to understand and express novel orderly relationships.'

There is a current trend for exploring the concept of cognitive enhancing drugs. Although many of these so-called *smart drugs* or nootropics available over-the-counter have little in the way of objective scientific validity, there remains a genuine furious exploration for such agents. Research in this field seeks the role of relevant receptor systems in learning and other cognitive processes. The use of D-cycloserine as an adjunct to psychotherapy is well studied (Ressler, *et al*. 2004), and a recent study by Harvey (2003) describes using LSD (a 5-HT_{2A} receptor agonist) to enhance associative learning in rabbits.

How is creativity measured?

Since renaissance times, creativity has often been measured in terms of examining the output of so-called *creators*. The sheer volume of works by Da Vinci and Michelangelo are frequently quoted as testament to their creative geniuses. However, defining objective measures for the process of creativity is notoriously difficult - especially when taking into account the subjective nature of an individual's aesthetic appreciation of a particular creation. Some scholars (Zinkhan, 1993) have argued that creativity, by definition, defies measurement because all tests have predetermined correct answers and originality is a requirement of creativity - therefore, any 'correct' answer in a creativity test could not be creative.

Tests to measure creativity fall into two broad categories - the more scientific psychometric tests and the more subjective, but widely used, method of 'Expert Opinion'. Many of the psychometric tests developed have arisen from Guilford's definition of creativity as a product of divergent thinking. Tests that measure divergent thinking include the 'Unusual Uses' test, the 'Structure Of Intellect' test and Mednick's Remote Associates Test (1962). The creativity researcher Paul Torrance (1974) further developed Guilford's tests to produce the Torrance Tests of Creative Thinking (TTCT), which tested divergent thinking and other problem-solving skills, through *Fluency*, *Flexibility*, *Originality* and *Elaboration*. Further related tests include the Starkweather Originality Test (1964) - for young children only - and the Group Inventory for Finding Creative Talent (GIFT) (Rimm, 1980).

Critics of psychometric tests have suggested that it is not possible to articulate clear, objective criteria for a creative product, but that if external appropriate judges can agree on a product's creativity, it can be accepted as such (Amabile, 1982), and this point of view underlies the evaluation of identifying creativity by Expert Opinion. Techniques include Amabile's Consensual Assessment Technique (CAT) (1982). The judgement of panels of esteemed experts in the relevant field continues to be a popularly accepted method for assessing creativity in the arts. For example, The Turner Prize and The Booker Prize.

Characteristics of creative people

'We are all, to a varying extent capable of creativity - we participate in it simply by thinking.' (Barron, 1965). In a slightly archaic qualitative study, Barron (1965) examined the psychological profiles of a large group of individuals from different professional fields who frequently produced highly creative, original work, such as mathematics, the physical sciences, architecture and creative writing. He used a variety of (mainly psychodynamic) psychological rating scales and diagnostic instruments to postulate a list of eight traits that characterised these highly creative individuals, as follows:

1. Creativity was not linked directly to IQ. Although intelligence is in some degree necessary, it is not alone a sufficient condition for high creativity.
2. Finding meaning in the world - and being enthusiastic and able to communicate that meaning to others in one form or other.
3. Being intuitive
4. Being introverted
5. Finding a simple explanation to a complex problem (and this refers to creativity in both art and mathematics).
6. Being slightly more 'psychologically imbalanced' (measured by Barron as 'schizoid tendencies') than the general population.
7. Ability to maintain independent judgement (even in the face of alternative peer consensus).
8. 'Maintenance of psychic opposites' - for example, individuals who displayed a tendency to be both free and disciplined or both 'masculine' and 'feminine'.

Rogers (1959) described how particular *internal* and *external* conditions are necessary to enhance the creative process. Internal conditions (many of which share similarities with Barron's descriptions of characteristics of creative people) include a low psychological defensiveness, a lack of rigidity, a permeability of boundaries in concepts, beliefs, perceptions and hypotheses, a tolerance for ambiguity, an ability to receive and integrate apparently conflicting information, a sensitive awareness of feelings and openness to all phases of experience, intuition, aesthetic sensibility, a sense of satisfaction in self-expression, the ability to think in terms of analogues and metaphors and the ability to 'toy' with ideas, shapes and hypotheses. Rogers' external conditions that facilitate the enhancement of creativity include an atmosphere of psychological safety and psychological freedom in which the subject is permitted to think and feel whatever is discovered within oneself.

How the psychedelic experience might enhance the creative process

The term 'Psychedelic Experience' was coined in the 1950s to describe the subjective psychological effects of the human user when under the influence of a hallucinogenic drug. Such drugs, which occur in abundance in many plants and fungi and may also be synthesised artificially, include lysergic acid diethylamide (LSD), mescaline (found in the *Peyote cactus*), dimethyltryptamine (DMT, the active component in Ayhuasca) and psilocybin (the active component found in many species of 'magic' mushrooms.)

The psychological experience induced in humans under the influence of psychedelic drugs is multifarious and idiosyncratic, but nevertheless a broad range of common characteristics are frequently identified. These include alterations in the user's perceptions (in all the sensory modalities), changes in the emotions and expansion in an individual's sense of thought and identity. A particular feature of the experience - that is encompassed by all the above characteristics and has special relevance to the creative process is, that of a general increase in complexity and openness, such that the usual ego-bound restraints that allow humans to accept given pre-conceived ideas about themselves and the world around them are necessarily challenged. Another important feature is the tendency for users to assign unique and novel meanings to their experience - together with an appreciation that they are part of a bigger, universal cosmic-oneness.

In the introduction to their original article describing a pilot study to explore the use of psychedelic agents in creative problem solving (below), Harman, *et al*. (1966) suggested that using a psychedelic drug under the appropriately controlled test conditions satisfies all of the criteria outlined by Rogers (above) to enhance the creative process.

Anecdotal historic examples of using psychedelic drugs to enhance artistic creativity

There are many anecdotal examples of artists and writers describing the use of psychedelic drugs such as LSD to enhance the creative process (and a similar number of such accounts disputing this suggestion). The use of drugs to enhance artistic creativity is not new, illustrated when the Roman poet Ovid said, 'There is no poetry among water drinkers.' There are examples of pre-historic art from all around the world, which use optical illusions or *entoptic phenomena* to enhance the visual experience. The linkages between this form of artwork and pre-historic use of psychedelic drugs is well established and described in the art work of many pre-historic cultures from Ireland (Dronfield, 1995), Africa and France (Lewin, 1991) to South America (Howard, 1957) and as far afield as Siberia in the Arctic circle (Dikov, 1971).

The use of opium (whilst not usually credited as a *psychedelic* drug) to influence creativity is well recognised. Thomas De Quincey describes the pleasures, as well as the pitfalls, of taking opium in *Confessions of an English Opium-Eater* (1822). The English Romantic poet Samuel Taylor Coleridge also reports the vivid imagery of the opium experience in his poem *Kubla Khan* (1816), as does Alexandre Dumas père, in *In The Count of Monte Cristo* (1844). And the 1832 poem by Alfred Lord Tennyson, *The Lotus-Eaters* describes how opium is used as a creative tool in the nineteenth century. In the 20th century, the French poet and playwriter Antonin Artaud used opium extensively, as well as the *Peyote cactus* (Artaud, 1937).

More recent examples of artists using psychedelic drugs include Henri Michaux, the Belgian-born French painter, journalist and poet, who at the age of 56 started using mescaline and cannabis and wrote about his experiences in his later works (Michaux, 1956). A now very famous account of the mescaline experience by the English intellectual writer Aldous Huxley in 1954 placed Huxley as a centrally revered figure for the subsequent cultural drug revolution that followed. Then since the 1960s, the volume of modern Western art and music that attributes its influences to the psychedelic drugs is vast. Some such artists and musicians openly proclaim themselves to be 'psychedelic artists,' whereas many others will frequently acknowledge the influence of psychedelic drug experiences have had on their work. One such piece of psychedelic drug-influenced artwork recently appeared in the *British Journal of Psychiatry* in homage to the discoverer of LSD, Dr Albert Hofmann (Sessa, 2007).

Oscar Janiger's unique study

An attempt to explore the value of the agent LSD in influencing artistic creativity was made in a remarkable long-term series of anecdotal case studies by the American psychiatrist Oscar Janiger (Dobkin de Rios and Janiger, 2003). Between 1954 and 1962, he facilitated LSD sessions for almost 1000 people between ages 18 and 81 in a variety of professions from doctors and nurses, lawyers, housewives and police officers to judges, truckers, students and the unemployed and retired. One of his participants was the film star Cary Grant. In contrast to the often highly systematised design of most other psychedelic research of this period, Janiger's experiments were largely unguided and took place in a naturalistic setting, with a view to explore what the nature of the 'intrinsic, characteristic LSD response' (if indeed there was one) might be. Unsurprisingly, the volunteer's experiences varied widely, but adverse reactions were extremely rare, and the vast majority described the experience as valuable and sustaining. During the course of this work two experiential characteristics emerged repeatedly - those of spontaneous spiritual experiences and those of LSD boosting the subjects' experiences of creativity.

These latter observations lead Janiger to conduct a parallel study examining the effects of the drug on creativity in a controlled setting. He subsequently gave LSD to a mixed group of 60 visual artists over a seven-year period, and they produced over 250 drawings that were later analysed by a professor of art history, who compared the artists' work before and after the LSD sessions. Because of the heterogeneity of the population and the aesthetic nature of analysing the results, making objective statements about how LSD effected the artists' creativity is impossible, but the drug did appear to enhance certain aspects of the artists' work; namely there was a tendency towards more expressionistic work, a sharpening of colour, a greater freedom from prescribed mental sets, an increased syntactical organisation, a deeper accessibility of past impressions and a heightened sense of emotional excitement. However, perhaps the most valuable aspect of Janiger's study is the many qualitative reports from the artists themselves, who without exception found the LSD experience artistically and personally profound.

Further experiments in creativity and psychedelics

An article by Stanley Krippner (1972) outlines five studies. In a study by Berlin, *et al*. (1955), four prominent graphic artists were given mescaline and LSD and encouraged to complete paintings whilst under the influence of the drug. A panel of art critics judged their subsequent paintings to have 'greater aesthetic value' than the artist's usual work.

The American psychologist Frank Barron (1965) gave psilocybin to creative individuals and recorded their subjective impressions. The psychiatrist McGlothlin, *et al*. (1967) gave 200 μg of LSD to 72 graduate students together with two control groups. In long-term follow-up, the experimental group showed a subjective greater appreciation of music and the arts, but no actual increase in creative ability.

In an experiment by Zegans, *et al*. (1967), 19 graduate students were given one of three varying doses of LSD, alongside 11 students who received a placebo. The subjects did not know they were to be given psychotropic drugs when they initially signed up for the experiment, and they were not selected for their creative abilities. A range of creativity test data (including the Mednick Association Test, the Modified Word Association Test, the Mosaic Design Test and the Free Association Test) were conducted at baseline, during and after the acute intoxication. Although results were not statistically significant, there was trend towards significance for the LSD group for all tests. One striking conclusion of the experiment was that whilst administering LSD to unprepared students did not result in a blanket statistically significantly improvement in creativity for all subjects, for certain subjects with particular 'creative personality traits', it was noted that LSD 'increased the accessibility of remote or unique ideas and associations to their conscious awareness'.

It is noteworthy that little emphasis was made towards the importance of (personal mind-) set and (environmental) setting during these studies - two very important factors that have been shown to radically alter the outcome of individual's experiences under psychedelic drugs. All these studies report the variable successes of demonstrating the psychedelic drug's ability to improve creativity in the experimental context - especially when subjects are taken from an unselected population of graduate students.

However, the pilot study by Harman, *et al*. (1966) from the Institute of Psychedelic Research of San Francisco State College deserves closer attention. The researchers took particular care to select individuals ($n = 27$) engaged in creative industries (engineers, theoretical mathematicians, physicists, architects and designers) and 'primed' them with a pre-drug session in which they were encouraged to select problems of a professional interest that required a creative solution. A very positive mind-set was, therefore, encouraged by the researchers, who told the subjects that the drug *would* enhance their creativity and help them to work more productively without distractions. Baseline psychometric tests included the Purdue Creativity Test, the Millar Object Visualisation Test and the Witkin Embedded Figures Test. At the psychedelic sessions (using mescaline) a few days later, subjects were encouraged to work in groups and as individuals to tackle their chosen problems and were subjected to further psychometric tests. Follow-up consisted of subjects submitting a written subjective account of their experience within 1 week of the drug session and further interviews with the researchers 8 weeks later in which subjects were asked whether the drug session had offered an impairment, no change or an improvement in their creativity and work performance. All participants showed enhanced abilities on all tests when under the drug compared with the previous non-drug tests ($P < 0.01$). In the subjective written accounts, all the participants described subjective enhanced effects of the drug on their creative process. From these qualitative reports 11 'Strategies of Enhanced Functioning' were extracted:

1. Reduced inhibition and reduced anxiety.
2. Improved capacity to restructure problems in a wider context.
3. Increased fluency and flexibility of ideas.
4. Increased visual imagery and fantasy.
5. Increased ability to concentrate.
6. Increased empathy with objects and processes.
7. Increased empathy with people.
8. Subconscious data more accessible.
9. Improved association of dissimilar ideas.
10. Heightened motivation to obtain closure.
11. Improved ability to visualise the completed solution.

At 8-week follow-up, all subjects reported either improvements or no change in their creative abilities - with no reports of impairments. Although this study is severely limited in not being double blind and placebo controlled, it reports the power of (and importance) of set and setting, and its potential implications for the creative industries is highly significant.

The commercial industry implications for enhancing creativity with drugs

A better understanding of creativity, how best to measure and, crucially, how best to enhance it, has vast implications for commercial industry. Above and beyond the artistic and neuroscientific interest in the creative process, practically all aspects of modern industry rely to some extent on the concept of product design - particularly in the advertising industry, where creativity is arguably the most important element of success (ElMurad and West, 2004). Despite the enormous amount of money and energy invested in such commercial industries, the scientific concept of *how* creativity is enhanced is poorly understood. This makes the neuroscientific understanding of these processes particularly relevant.

There have been some notable historical examples of designers using psychedelic drugs to improve their skills.

One such example, from 1965, is when the architect Kyoshi Izumi was asked to design a psychiatric hospital in Canada and decided to take LSD (as a psychotomimetic) and perform extensive visits to old mental institutions in an attempt to see the wards in a new light. He found himself terrified by the standard hospital paraphernalia such as the tiles on the walls, the recessed closets and the raised hospital beds. There was no privacy, and the sense of time was nil, because of the absence of clocks and calendars. After his LSD insights, Mr. Izumi was able to design what has been called 'the ideal mental hospital.' The first was built in Yorkton, Saskatchewan, and five others have been modelled upon it elsewhere in Canada (Stafford and Golightly, 1967).

Another possible example of the creative influence of psychedelic drugs comes from the alleged use of low doses of LSD by the Nobel Prize winner Francis Crick, who discovered the double-helix structure of the DNA molecule in Cambridge in the 1950s. The drug was freely available at that time as a tool for psychotherapy. Crick was a well-known admirer of Aldous Huxley and went on to campaign for the legalisation of cannabis in the 1960s as a founder member of the 'Soma' group - named after Huxley's mythical drug from the book Brave New World.

Another incidence of psychedelic drug-induced creativity from the scientific community comes from the Nobel Prize winning chemist Dr Kary Mullis, the inventor of PCR, who is quoted as saying: 'Would I have invented PCR if I hadn't taken LSD? I seriously doubt it,' he says. 'I could sit on a DNA molecule and watch the polymers go by. I learnt that partly on psychedelic drugs.'

A further striking example of psychedelic drug-enhanced creativity of industry comes from the well-established computer industry in California. The liberal atmosphere and loose approach to creativity fostered by the 1960s use of LSD on the West Coast of the United States spawned a population a creative post-hippie entrepreneurs. Pioneers such as Steve Jobs and Steve Wozniak, founders of the Apple computer industry, were both products of the 1960s counter-culture who were part of a group of visionaries setting out to turn computers into a means for freeing minds and information (Markoff, 2006).

Clinical implications of drugs that may enhance creativity

Perhaps the most obvious clinical area that may benefit from an enhancement of creativity is autism. A common problem in patients with autism is the inability to see the intrinsic (and sometimes abstract) connectivity between people and objects. One of the central tenants of the psychedelic experience is its ability to encourage the user to find new meaning in and see associations between objects and feel part of the abstract connectivity of the universe. Although these are subjective effects enhanced only acutely during the psychedelic experience, they are experiences enjoyed by most people to a lesser degree at all times. In autism, such experiences are frequently impaired. This phenomenon was explored in the early part of the 1960s in a small number of studies using psychedelic drugs on children with autism (Mogar and Aldrich, 1969). Most subjects were between 6 and 10 years old, and all were considered severe cases of autism who had failed to respond to other forms of treatment. Consistent effects of the psychedelic drugs included improved speech in otherwise muted patients, a greater emotional responsiveness to other children and adults, increased positive mood with frequent smiling and laughter and decreases in obsessive-compulsive behaviour. The collective results argued strongly for more extensive research, but this, like all psychedelic research by the end of the 1960s, did not materialise because of socio-political reasons (see Sessa, 2005).

Set and setting

That the classical psychedelic drugs (LSD, Mescaline, DMT and Psilocybin) produce very variable psychological characteristics is undeniable. The role of fostering a positive set and setting is crucial to a positive outcome. This is also true for MDMA - which is generally accepted to produce an overwhelmingly positive mood for most users but is also subject to negative experiences in a minority of cases particularly when users have been given negative information about the drug's effects. Therefore, in exploring psychedelics as clinical tools, the concepts of set and setting ought not to be seen as *confounders* but rather as an *active* part of the experimental intention. The totality of the psychedelic experience is a combination of pharmacological and psychological factors interacting together in a synergistic fashion; set and setting must be seen as essential components of the psychedelic experience that must be attended to achieve a maximum positive response. Although this is true for *all* clinically used psychotropic drugs to a certain extent (and SSRIs, for example, can have placebo efficacy rates of up to 45%), it is especially so of the psychedelic drugs. Therefore, studies that either deliberately or unintentionally disregard these set and setting factors and report negative outcomes ought not to be used as evidence to dispute the positive potential of psychedelic drugs.

It is well accepted that when under the acute influence of psychedelic drugs, performance on standard tests of intelligence, learning, memory and other cognitive functions, as well as certain psychomotor tasks, generally show impairment and sometimes show lack of change and only rarely show improvement (Carter, *et al.*, 2005). However, it is often difficult to get meaningful data from such measurements because subjects frequently become engrossed in the subjective aspects of the drug experience and lose interest in the tasks presented by the investigators. Psychological tests are often seen as absurd or irrelevant by the subjects, illustrated well by this quote from the psychologist Arthur Kleps (1967), 'If I were to give you an IQ test and during the administration one of the walls of the room opened up, giving you a vision of the blazing glories of the central galactic suns, and at the same time your childhood began to unreel before your inner eye like a three-dimension colour movie, you too would not do well on an intelligence test.'

What is the benefit of revisiting psychedelics and creativity research now?

Psychedelic research's current renaissance is spurred on in part by a more realistic understanding of the safety profile of recreationally abused substances. LSD and MDMA were recently categorised far down the list of the potential hazards of 20 commonly abused substances (Nutt, *et al.*, 2007). The political climate is beneficial for exploring the therapeutic possibilities of such drugs that have hitherto been considered off limits simply because they have been used recreationally. There are several trials underway throughout the world at present - some of which are aiming to recreate some of the famous studies of the 1950s and 1960s using modern research methods. One such trial recently recreated was Walter Pahnke's *1962 Good Friday Experiment* (Pahnke, 1969) in which psilocybin was seen to induce a subjective experience of spirituality in its users. In the famous 1960s experiment, Pahnke (who was both a physician and a religious minister) used a double-blind technique to administer 30 mg of psilocybin to 10 experimental subjects, whereas a further 10 subjects received an active (but nonpsychedelic) placebo (nicotinic acid). All the subjects, who were Harvard theology students, then attended Good Friday Mass at Boston University's Marsh Chapel. Their subjective account of the experience was measured using the 'Stace Criteria' - a well-established scale for measuring the degree of mystical experience. In his 2006 recreation of Pahnke's study, Roland Griffiths of the Johns Hopkins School of Medicine in Baltimore, USA used a double-blind technique and gave psilocybin to 36 volunteers without previous experience with hallucinogens, using a matched-control group who were given methylphenidate (ritalin) as an active placebo. The degree of mystical experience was measured using a questionnaire developed by Ralph W Hood (2001). Sixty-one per cent of the psilocybin subjects reported a 'complete mystical experience', compared with only 13% of the methylphenidate group. Griffiths followed-up the subjects at 2 months and found that 79% of the psilocybin subjects reported moderately to greatly increased life satisfaction and sense of well being. It is noted that there were also some significant negative subjective experiences, with 36% of the psilocybin subjects participants describing a strong to extreme 'experience of fear' during the psilocybin session (which was not reported by any subject during the methylphenidate session), with about one-third of these (13% of the total) reporting that this dysphoria dominated the entire session. (Griffiths, *et al.*, 2006). It is difficult to imagine the obvious clinical benefits of such a study, but heartening to see such an experiment that further expands our understanding of neuroscience. A recreation of the previously mentioned study by Harman, *et al.* (1966) would provide similar data to the neuro-scientific community, and as mentioned it could also have far greater implications for clinical and commercial sectors of society.

Conclusion

As with all psychedelic research, planning new projects using drugs that have a contentious history needs to be done cautiously to avoid the (often inaccurate) preconceptions about the relative usefulness and harm of these substances. However, common to all these drugs, there exists a rich wealth of anecdotal studies from 40 years ago that were abandoned prematurely before their full therapeutic potential was either adequately reported or discounted. The area of psychedelic enhancement of creativity is one such area that may have potential benefits for furthering our understanding of neuroscience. In addition, if we are to strive to comprehend the brain and mind in their entireties, these are areas that are worth revisiting with modern research methods.

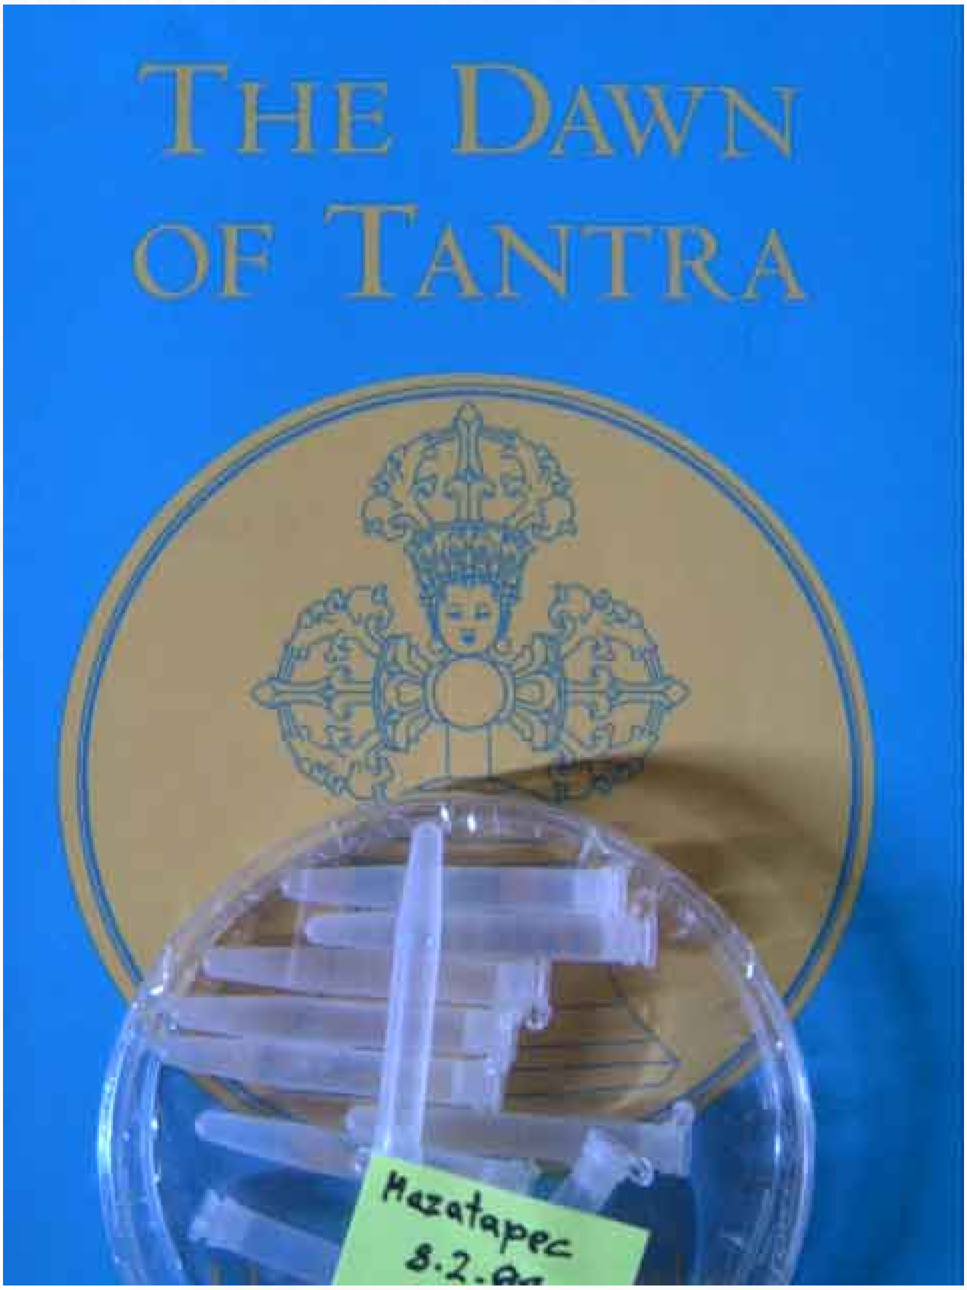
Practical method for long term storage of mycellium in dH2O using ependorf tubes as vials

by

Quincunx

original source: http://www.shroomery.org/8511/Practical-method-for-long-term-storage-of-mycellium-in-dH2O-using-ependorf-tubes-as-vials



background:
This is a simple method (TEK of some kind) i use to store mushroom mycellium cultures in dH2O for prolonged time. It is far from being ideal but i thought it could come handy for some of you (read the part about mailing cultures stored like this). Feel free to improve it. I came up with it because i couldn't find any appropriate TEK at The Shroomery FAQ about dH2O storage.

primary objectives:

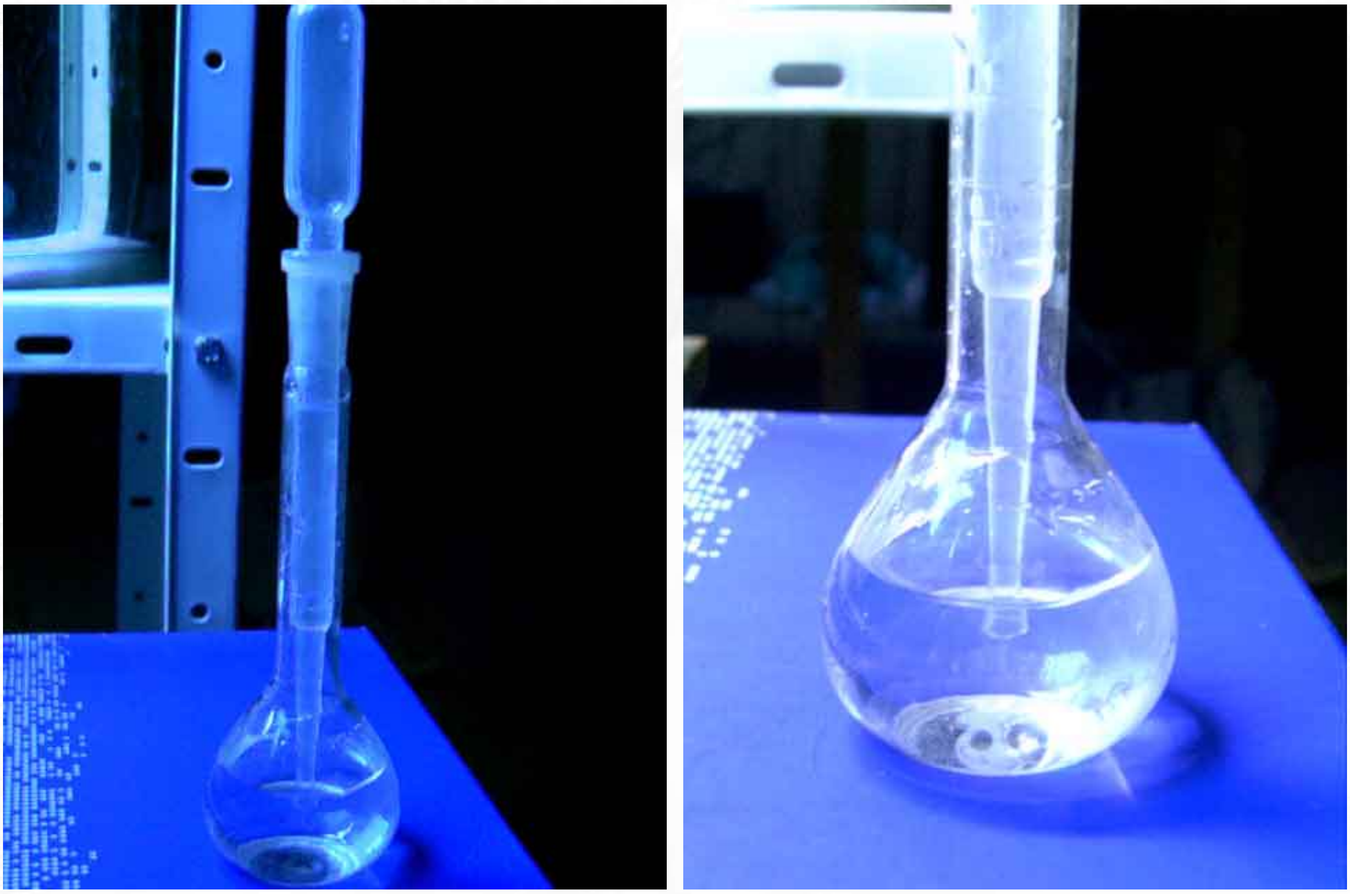
- at least 50% of isolates should survive a period of 2 years
- isolates should be stored in as small containers as possibile

secondary objectives:

- isolates should survive occasional temperature fluctuation
- vials should be crash resistant to survive mail shipping & handling
- method/TEK should be simple and cheap so anyone can use it

materials used:

- 0.5 mL PP ependorf tubes
- dripping-tube or a pipette - pick one that will fit into neck of your flask:



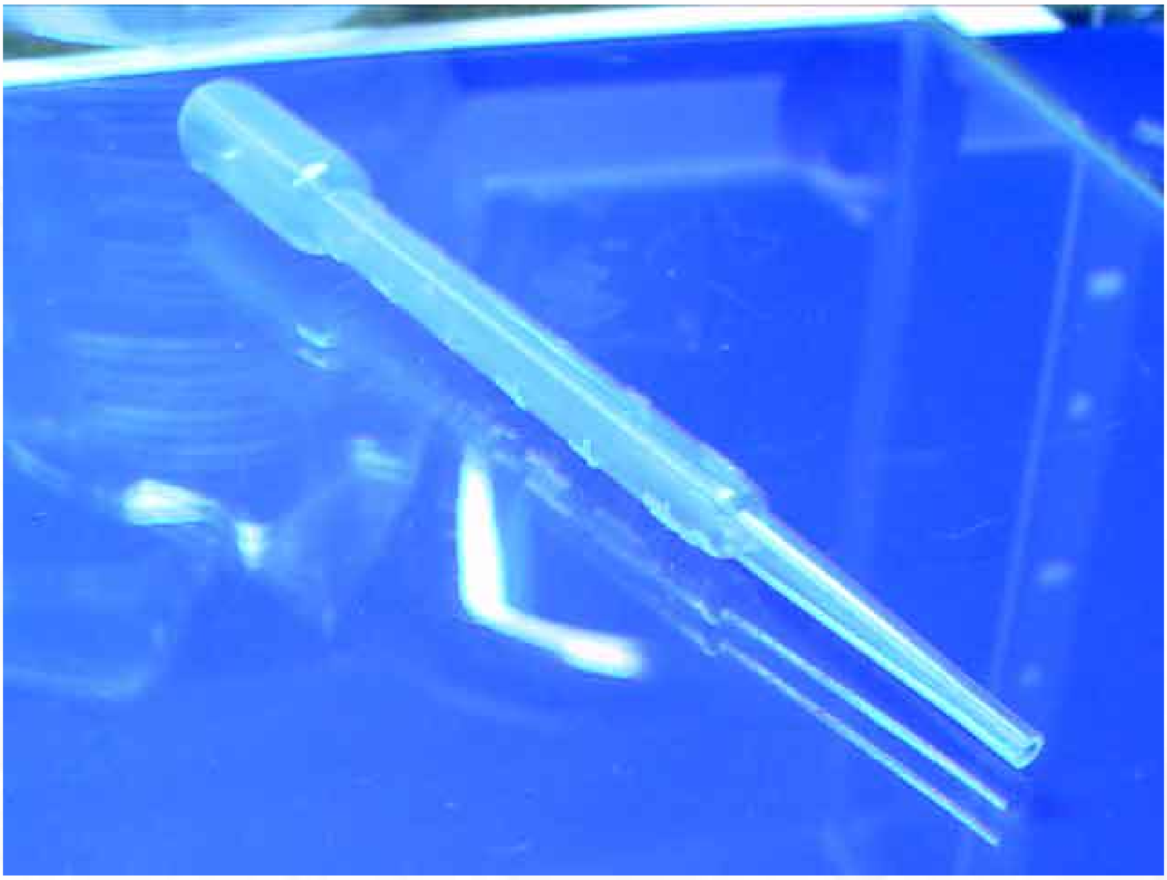
- cotton bud sticks
- small flat bottom flask or erlenmeyer flask or even standard test tube will do
- pure dH2O (bottled spring water is drinkable and contains minerals - i'm not sure if this is good in this case)

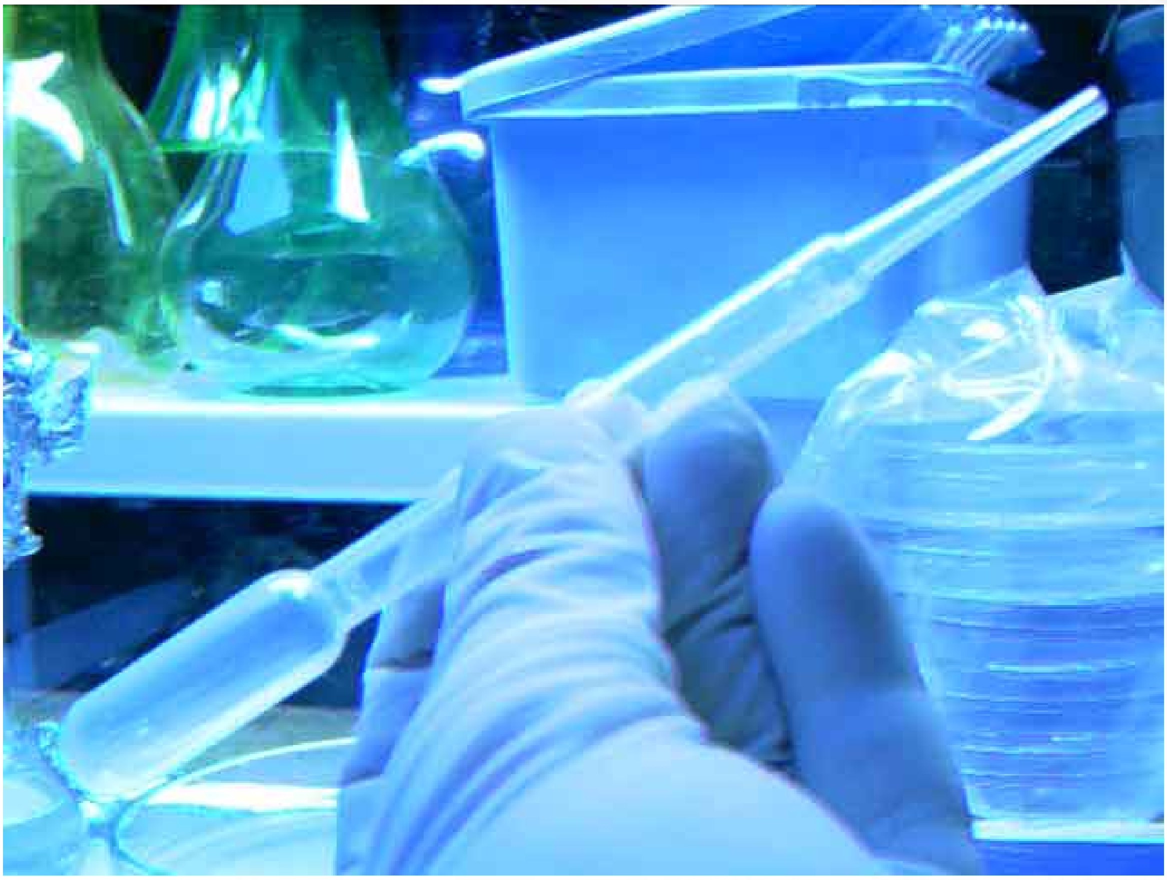
High sterility is a must so think in advance and sterilize everything. If possibile find presterilized cotton buds (pharmacy), ependorfs and plastic dripping tube. Otherwise make sure that materials can withstand PCing.
I've found cotton bud stick as the best tool for removing mycellium from the surface effeciently with a minimum of agar material transfered as well. Spatula and/or scalpel will work too, but they are too sharp for me - mycellium will deposit on the edge and form hard to break clumps once transfered in dH2O. Also, one

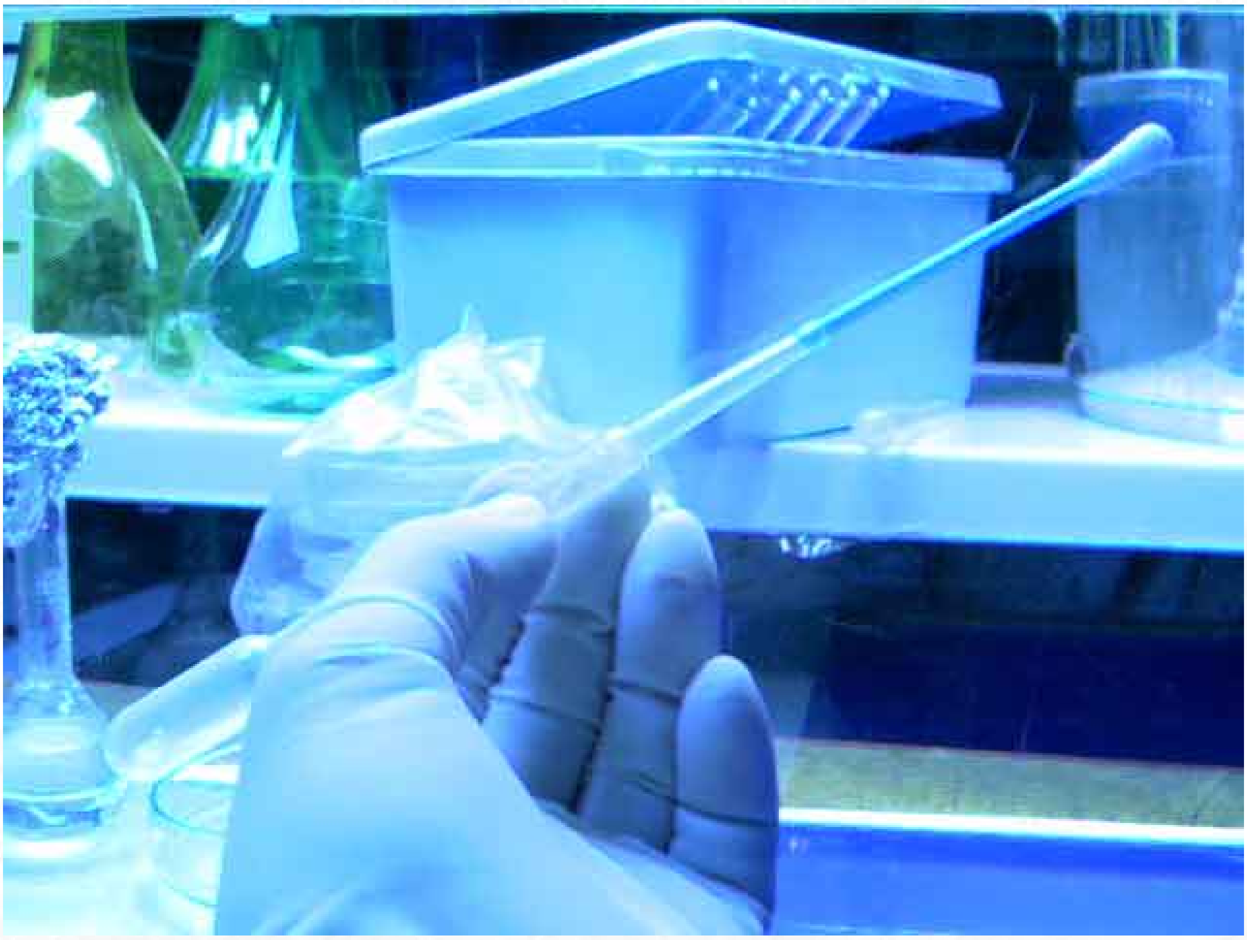
false move and you can dig deep into agar. Suntzu gave me the original idea with sterilized swab (thanx) so i've pondered on this and came up with sticks.

Ok. Here's my method.

First i cut a stick (it's hollow) at the base and fit it at the end of the dripping-tube to construct a simple tool like this:

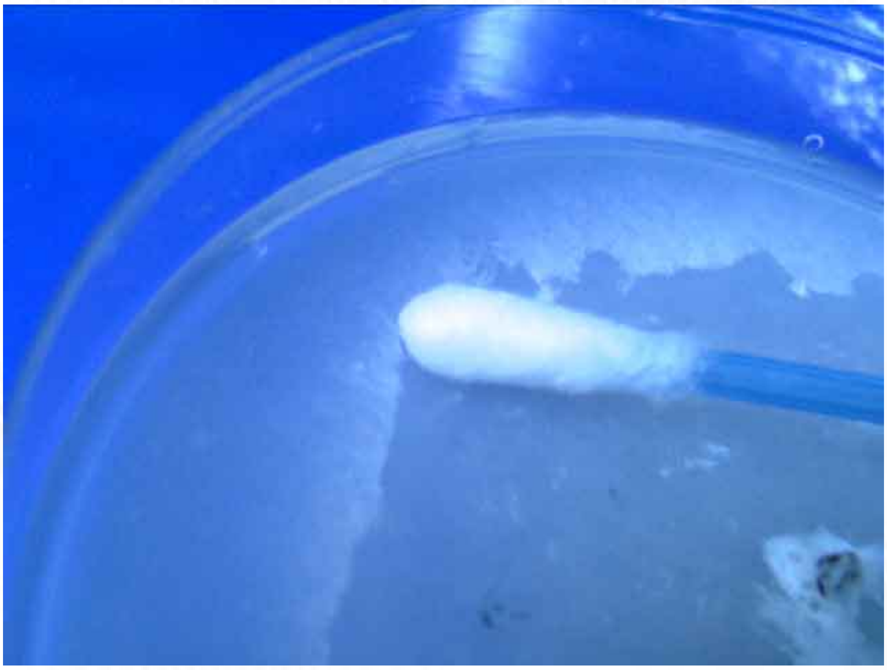




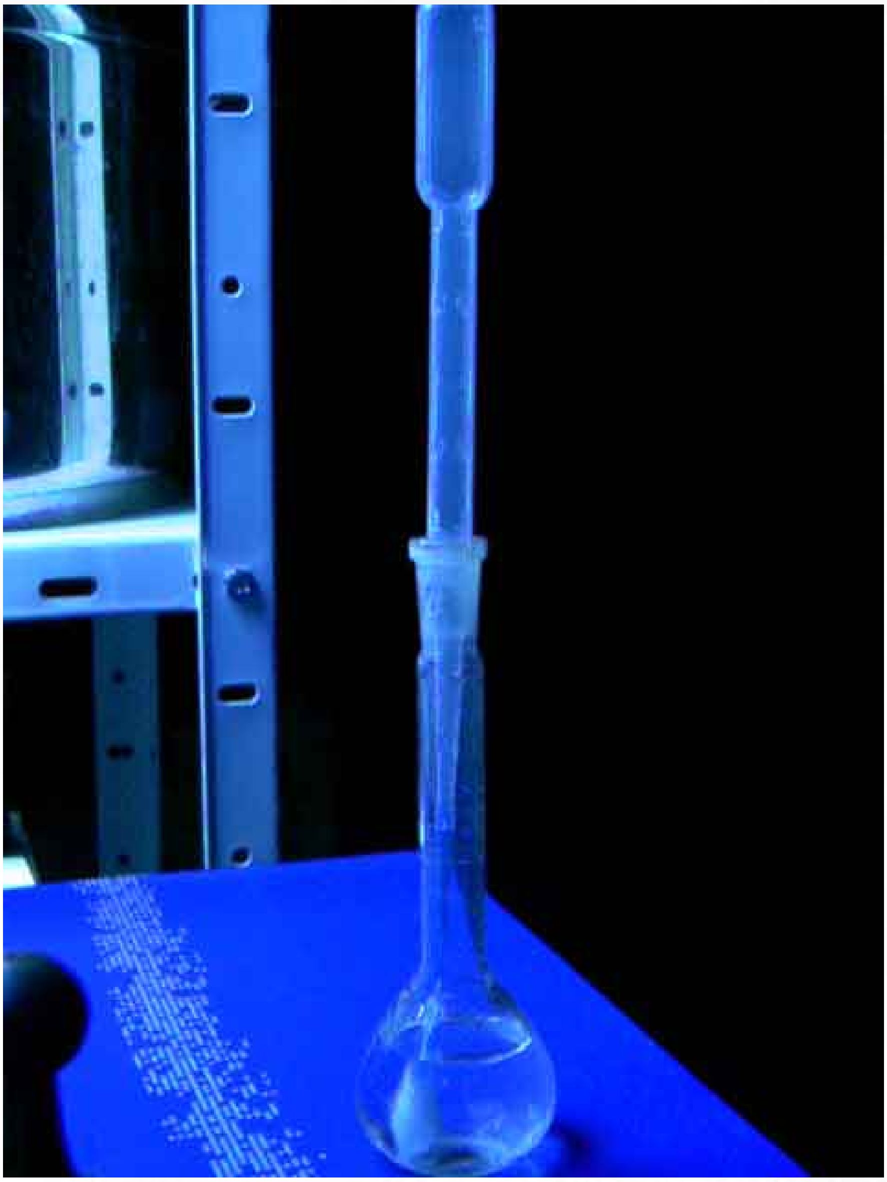


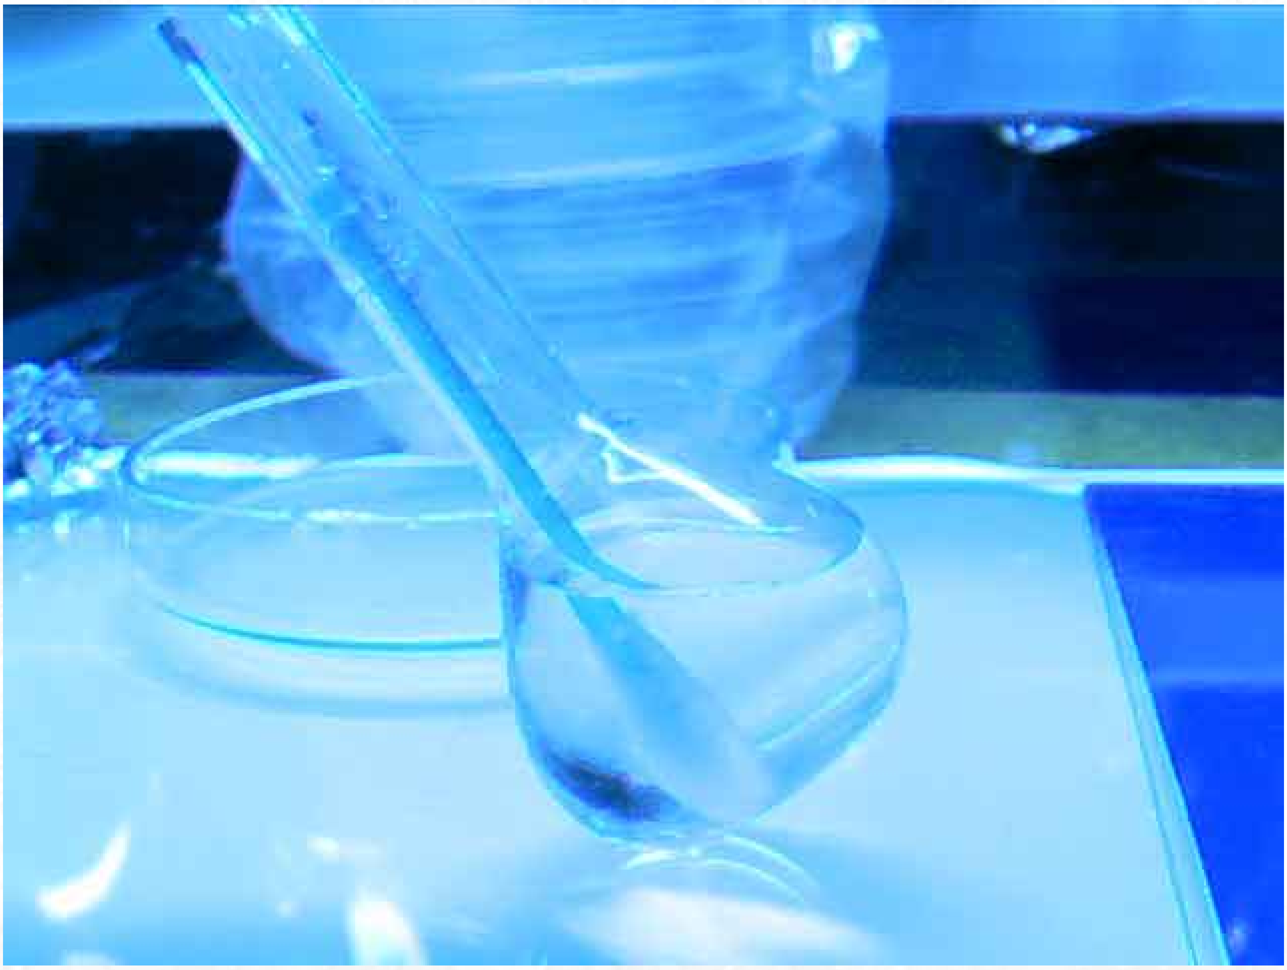
Then take a Petri dish (colonized as needed) and roll the stick over surface:

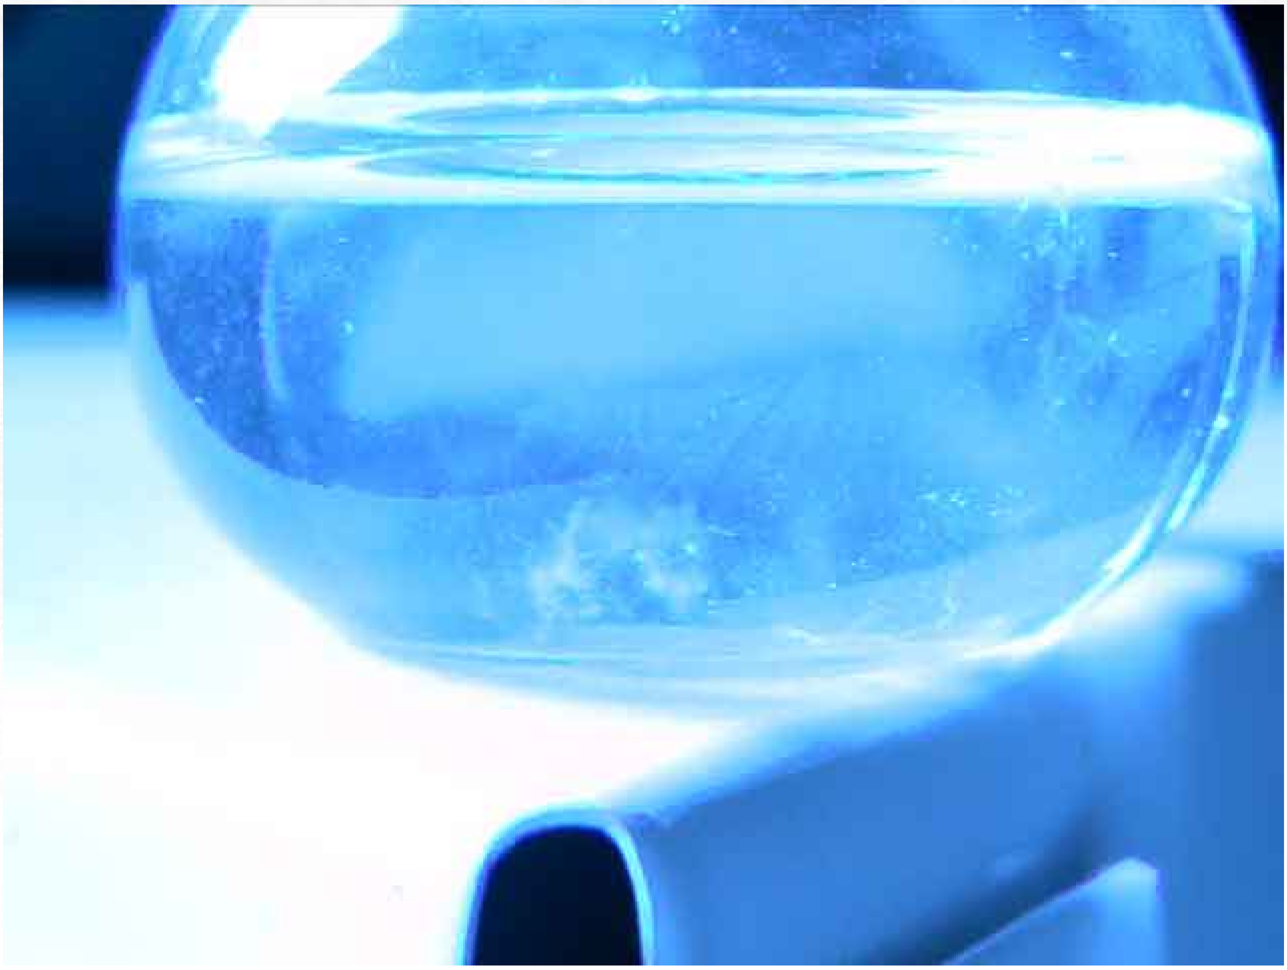
Cambodia
30.1.
13
22.1.03
MZ
MZ 22.1.03



You can gently wipe mycellium out of agar surface and even if you touch the surface with the bud tip it will feel like waxed solid floor (unlike with scalpel or spatula). Then transfer to flask with dH2O (constructed tool is thin and more than long enough to fit the neck of the flask):



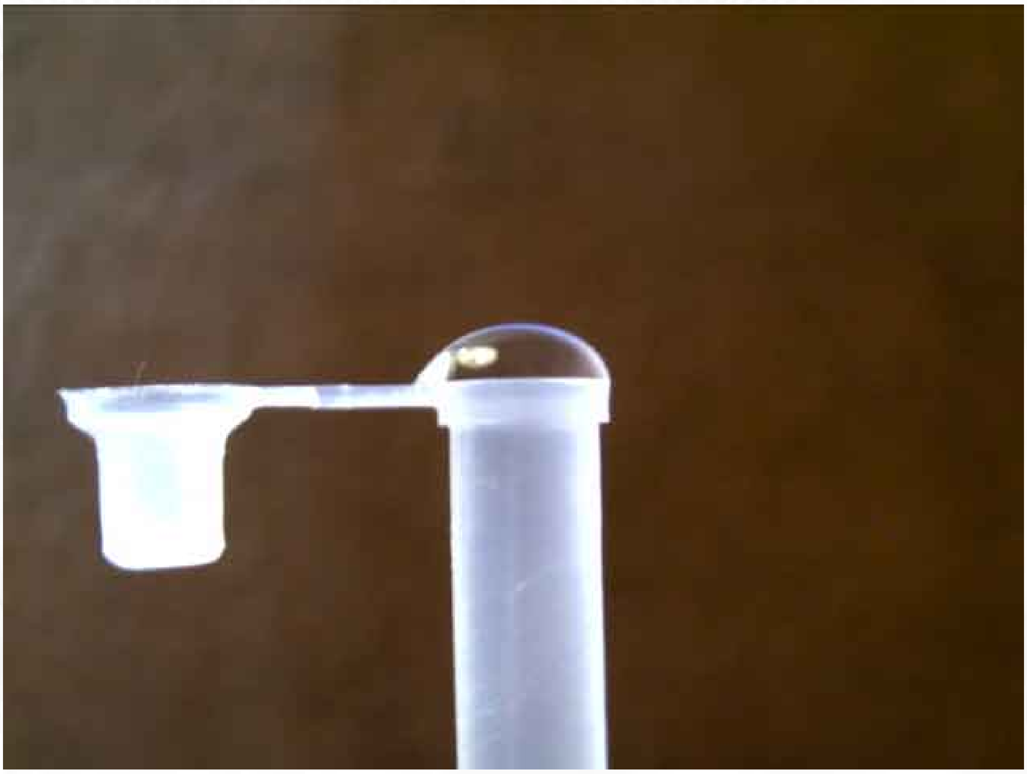




Once in water, gently press dipping-tube nozzle to push some air through stick and shake - this will release the mycellium from the cotton bud. Do not release the nozzle again until you remove the stick from water otherwise it will suck the mycellium back on the cotton bud.

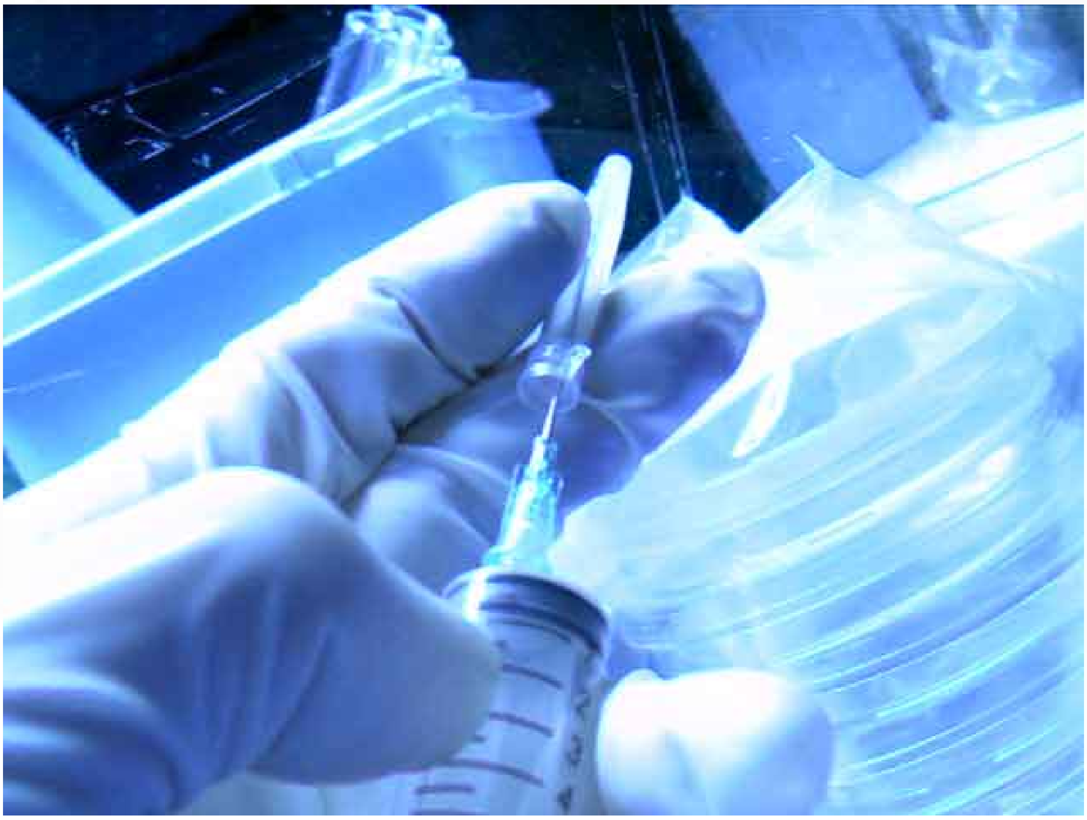
Once suspention is dense enough, stir the flask some more. Now it is time to fill those little ependorfers. This can be tricky and requires still hand and patience (side note: it is a nice workout for those of you that are deep int E7D o the zen or yoga to improve mind concentration).

Remove the stick from the end of dipping tube and fill it with mycellium suspension. Then slowly dip the suspension into ependorfers all the way up, be carefull to remove all air bubbles (tricky thing due to capillarity) until they are full like this:



... and seal them. If they are not filled all the way up and above some air can remain inside.

Well. This is it. After some practice you'll find the method quick and easy to perform. 0.5 mL is enough to inoculate a lot of fresh Petris and more than enough to start a single 750 mL jar with grain spawn. Also, since PP ependorfers will not break easly and are small enough and mycellium stored like this can sustain a lot of temperature fluctation, they are great for discreet mailing in almost any envelope. (a hint: they will fit into any cheap pen and if X-rayed it will seem like spare ink container) The reciever does not need a pipette or anything. A sterile needle and syringe will do. Just wipe the plug of the ependorf with some alcohol and stick a needle through and pull the syringe bat like this:



Wishing you all healthy crops.

The Metabolic Pathway of Psilocybin Production

by

micro

original source: http://www.shroomery.org/6227/The-Metabolic-Pathway-of-Psilocybin-Production

Metabolic pathways are important to understand when you are trying to produce a certain chemical from a living organism. Psilocybin is produced starting from chorismate, which is produced on the Shikimic Acid pathway. The Shikimate pathway is present in many different plants, fungi and bacteria, but is not present in animals, and is important for producing many different aromatic compounds, including many antibiotics and the tryptamine-based psychedelic drugs, like DMT, the ergot alkaloids and psilocybin. It is extremely important to know the metabolic pathway in order to do any scientific investigation of its production. The idea of this paper is simply to list all of the products and enzymes so one can look them up, if the need arises.

The first main step is the Shikimate pathway which is carried out in the cytosol of the fungal cells. This produces a product called chorismate which is used for the synthesis of folate, ubiquinone, phenylalanine, tyrosine and tryptophan. This pathway starts off with phosphoenolpyruvate, a product of glycolysis, and erythrose 4-phosphate, a product of the pentose phosphate pathway (a byproduct produced via a transketolase enzyme) that acts as a phosphate donor. These pathways are illustrated below. The pathway looks like this, starting with the starting products and then continuing with the enzyme on the right, which produces the next product:

Product	Enzyme
Phosphoenolpyruvate + erythrose 4-phosphate	DHAP Synthase =>
7P-2-dehydro-3-deoxy-d-arabino-heptonate	3-dehydroquinate synthase =>
Dehydroquinate	3-dehydroquinate dehydratase =>
Dehydroshikimate	Shikimate 5-dehydrogenase =>
Skikimate	Shikimate kinase =>
Shikimate-3-P	EPSP synthase =>
5-0-(1-carboxyvinyl)-3-phosphoshikimate	Chorismate synthase =>
Chorismate	

Chorismate can now go to any of 5 different pathways; we're concerned with the tryptophan pathway:

Product	Enzyme
Chorismate	2-deoxyisochorismate synthase =>
2-amino-2-deoxychorismate	Anthranilate synthase =>
Anthranilate	Anthranylate-phosphoribosyl transferase =>
N-(5'phosphoribosyl) anthranilate	N-(5'phosphoribosyl) anthranilate isomerase =>
Enol-1-0 carboxyphenylamino-1-deoxyribulose phosphate	indole-3-glycerolphosphate synthase =>
Indole-3-glycerolphosphate	Tryptophan synthase (a subunit) =>
Indole	Tryptophan synthase (b subunit) =>
Tryptophan	Tryptophan decarboxylase =>
Tryptamine	

Tryptophan is decarboxylated via an enzyme called tryptophan decarboxylase to form tryptamine. This is the last major step in the pathway that is significantly inhibited by a self-feedback downregulation mechanism, meaning that if too much of a particular substance is in the cells the enzyme will stop converting tryptophan to tryptamine. Here is a list of some inhibitors of tryptophan decarboxylase (copied from a paper at the lycaeum; unknown URL:)

Inhibition of Tryptophan Decarboxylase

Type of inhibition	Inhibitor	% Inhibition
Competitive Inhibitors:	N,N-dimethyltryptamine	65
	Indole-3-acetic acid	60
(Unknown Mechanism:)	Tryptamine	62
	5-Hydroxytryptamine	45
	Indole-3-acetaldehyde	50
Non-Inhibitors:	5-Methoxy-N,N-dimethyltryptamine	(0)
	5-Methoxytryptamine	(0)
	Indole-3-pyruvic acid	(0)

The pathway for the conversion of tryptamine to psilocybin and psilocin is still unclear, but it is proposed that there are many different steps, since the phosphorylated intermediates baeocystin and norbaeocystin are produced, in addition to psilocybin, which is most likely produced via one phosphorylase enzyme from psilocin. The experiments by Gartz *et al*. regarding an addition of tryptamine hcl to the substrate showed an increase in psilocin levels compared to psilocybin which suggests the downregulation of a phosphorylase enzyme at this step, and also provides some possible insight to the evolution of psilocybin in mushrooms.

PRIMARY PATHWAYS:

Both of the starting materials of the Shikimic Acid Pathway, phosphoenolpyruvate and erythrose 4-phosphate, are ultimately a product of glucose. Glucose is phosphorylated by ATP, which loses a phosphoryl group to glucose to become ADP:

The Glucose 6-P is then used on two different pathways, glycolysis and the Pentose Phosphate Pathway to produce our two starting materials.

Phosphoenolpyruvate is produced as a byproduct of glycolysis:

....and Erythrose-4-P is produced as a biproduct of the Pentose Phosphate Pathway:

Charcoal's Secret

by

JaComet

original source: http://www.shroomery.org/forums/showflat.php/Number/6024742

Somewhere in Stamets' work, and possibly on the boards, I noted that charcoal may be helpful where spores are difficult to start. Adding charcoal to culture media seems to be beneficial. I don't know what it does but I do know a bit about charcoals.

Charcoal has a secret. Not a secret really, just largely unrecognized outside of Asia. Some charcoal gives off far-infrared radiation. Not just while it is burning, it radiates all the time. Far-infrared = thermal radiation. Some charcoals even emit negative ions. With this in mind, let's look at how we may employ it's unique properties.

First let's look at regular and "activated" charcoal.

Regular charcoal is produced where hardwoods, sawdust, bone char, coconut shells, peat, coal or petroleum coke are fired in an enclosed burning environment. Restricting the amount of air provided to the burn runs off the water and volatile organic constituents in the wood, leaving blackened chunks of carbon mixed with traces of minerals from the original material.

Activated charcoal is made by taking regular charcoal and re-firing it with introduction of air blast, steam, oxygen or other gases to corrode the interior cell structure, creating a more porous structure. Activated charcoal attracts and retains organic matter run through it, as well as mechanically trapping particulate matter. These properties make it useful in a variety of applications, notably in water filtering.

Now let's look at infrared radiation and wavelengths.

When regular charcoal is burnt infrared radiation is released. This penetrating thermal radiation is what makes charcoal grilled foods different from flame grilled or broiled. The food is cooked on the inside by the radiation, reducing cooking time and sealing in juices as the out side is sealed by charring.

As stated earlier some charcoals give off infrared radiation all the time. Activated charcoal may give off infrared. I don't know. I expect this property may be dependent on the starting materials, but I've not found any information in these regards.

Now here is where things get interesting.

Journal of Chemical Engineering of Japan, vol 25 no 3 pp 275-281(1992) [Japanese]

EFFECT OF FAR-INFRARED IRRADIATION ON PASTEURIZATION OF BACTERIA SUSPENDED IN LIQUID MEDIUM BELOW LETHAL TEMPERATURE

ATSUSHI HASHIMOTO, JUN SAWAI, HIDEO IGARASHI AND MASARU SHIMIZU

Department of Chemical Engineering, Division of Chemical & Biological Science and Techr Tokyo University of Agriculture & Technology, Tokyo 184

The purpose of this study is to examine the influence of far-infrared irradiation on pasteurization of bacteria suspended in liquid medium below the lethal temperature. Under this condition, Escherichia coli and Staphylococcus aureus are injured and killed by far-infrared irradiation. With increase in irradiation power and with decrease in depth of the suspension, the ratio of the number of injured cells to the number of viable cells becomes higher, and the number of viable cells becomes smaller. Moreover, the pasteurization effect can be enhanced by raising the bulk temperature of the suspension. By estimating the temperature distribution within the suspension, it is suggested that the test bacteria are injured and killed in the very thin domain near the surface of the suspension.

+++

Journal of Chemical Engineering of Japan, vol 25 no 6 pp 666-671(1992) [Japanese]

FAR-INFRARED IRRADIATION EFFECT ON PASTEURIZATION OF BACTERIA ON OR WITHIN WET-SOLID MEDIUM

ATSUSHI HASHIMOTO, HIDEO IGARASHF AND MASARU SHIMIZU

Department of Chemical Engineering, Division of Chemical & Biological Science and Technology, Tokyo University of Agriculture & Technology, Tokyo 184

The present purpose is to study the influence of far-infrared irradiation on pasteurization of Escherichia coli and Staphylococcus aureus on or within a model for wet-solid food. Agar medium was used as the food model. By determining the thermal resistances of the test bacteria, the pasteurization effect of far-infrared irradiation (radiative heating) was compared with that of hot-air heating (a conventional method) from the viewpoint of thermal death kinetics. It was found experimentally that far-infrared irradiation is more effective than hot-air heating for the test bacteria on the agar-plate. Moreover, it is suggested that the surface temperature of the pasteurization sample irradiated by far-infrared radiation is higher than that measured by the thermocouples.

+++

So, what does all this have to do with anything?

Heated and evaporated water readily absorbs infrared radiant energy at 3, 4.5 and 6 µm.
I suggest this radiation can affect water in bacterial cells, killing them.

Enter Bamboo Charcoal!

Bamboo Charcoal has the possibly unique properties of emitting infrared rays in the range between 4 and 16µm, even at room temperature, along with negative ions and canceling electromagnetic (EM) radiation. Negative ions also disable or kill bacteria.

A Russian research team headed by A L. Tchijevski found an exponential bacteria decay rate of 78 percent per minute in negatively charged air environments. The team concluded negative ions killed the bacteria. Other studies indicate negative ions also kill or disable viruses and fungus spores.

But why are ions therapeutic? Partly because they kill germs. Back in the 1930s. a Russian team headed by A L. Tchijevski found that large ion doses of either polarity retarded bacteria colony formation on plates. Ionization also sterilized enclosed air. Latter experiments duplicating Tchijevski's work noted an exponential bacteria decay rate of 23 percent per minute for untreated air 34 percent per minute for air with pos-ions. and 78 percent per minute for negatively charged air. They concluded that the pos-ion decay rate was due to simple bonding or the ions with the bacteria, whereas the neg-ions actually killed them.

Some studies suggest that negative ions also have a biological effect on bacteria and viruses, killing them on contact in many cases.

Bamboo Charcoal is much more porous than other types, typically reaching surface areas of 300 to 700 square meters per gram. Wood charcoals area is around 30 square meters per gram. Coconut shell is somewhat higher. Bamboo Charcoal therefore is superior in many respects for filtration and absorption.

Bamboo Charcoal is high density and is very porous. It soaks up and releases moisture helping to maintain equilibrium. It is also a rich source of trace minerals, which it releases slowly to water.

Biological organisms absorb infrared in the 8-14 µm range utilizing the energy for a variety of metabolic processes.

Enough for now. Ponder how you might add this knowledge to your culture techniques, keeping in mind that liquid cultures may benefit where spores may not.

More to come as my trials continue.

Remember you heard it here first.

Mapping the Mycelial Network

by

John W. Allen, Jochen Gartz and Gaston Guzmán

The Resonance Project
Issue 2, Winter 1997/98

original source: http://www.erowid.org/plants/mushrooms/references/other/1997_allen_resproject_1.shtml

It's only been forty years since R. Gordon Wasson rediscovered the traditional use of hallucinogenic fungi in Mesoamerica, but in that time more than 160 species of psilocybian mushrooms have been identified worldwide (Allen, Gartz & Guzmán, 1998 [1992]). In 1957, only seven species were recognized within the scientific community, and outside of Mesoamerica their existence was known to only a small handful of scientists who investigated their restricted use among several groups of indigenous peoples native to Southern Mexico; primarily within the Mexican state of Oaxaca.

To this day, researchers have identified the existence of hallucinogenic psilocybian mushrooms as far north as Alaska and Siberia in the Northern Hemisphere, and as far south as Chile and Australia in the austral floral zone. Psilocybian mushrooms grow from California in the western United States to China and Japan in the east. Since the ecological and geographical distribution of the more than 160 species of hallucinogenic mushrooms is so vast and diverse, we have decided to present a geographical table of their distribution.

The following article presents a detailed listing of the various species of mushrooms which can be found from state to state in both the United States and Canada. A country by country listing of global distribution is also in the works, and will be available soon. References and more information are given at the end of the article.

UNITED STATES

Alabama

Gymnopilus spectabilis (Hesler, 1969)
Psilocybe caerulescens Murr. (Guzmán, 1983)
Psilocybe cubensis

Alaska

Amanita muscaria
Psilocybe cyanescens Wakefield. (Guzmán, 1983; Stamets, 1996)
Panaeolus ater (Lange) Kühner & Romagnesi. (Pollock, 1976)
Panaeolus subbalteatus Berkeley & Broome. (Miller et al., 1982)

Arizona

Gymnopilus sapineus
Gymnopilus spectabilis

California (San Francisco to Oregon)

Amanita muscaria
Copelandia cyanescens (Arora, 1986)
Copelandia tropicalis
Gymnopilus aeruginosus (Peck) Singer. (Stamets, 1996)
Gymnopilus liquiritae
Gymnopilus luteofolius (Peck) Singer. (Stamets, 1996)
Gymnopilus sapineus
Gymnopilus spectabilis
Hypholoma popperiana
Panaeolus fimicola
Panaeolus papilionaceus
Psilocybe azurescens Stamets Gartz. (Stamets, 1996). (Introduced)
Psilocybe baeocystis
Psilocybe cyanescens Wakefield. (Guzmán, 1983).
Psilocybe cyanofibrillosa
Psilocybe pelliculosa (Smith) Singer & Smith. (Guzmán, 1983)
Psilocybe semilanceata (Fr.) Kummer
Psilocybe stuntzii Guzmán & Ott. (Guzmán, 1983)

Colorado

Conocybe cyanopus (Atkins) Kuhner. (Stamets, 1993)
Gymnopilus sapineus
Panaeolus papilionaceus

Florida

Gymnopilus aeruginosus (Peck) Singer. (Stamets, 1996)
Gymnopilus luteofolius (Peck) Singer. (Stamets, 1996)
Gymnopilus sapineus
Copelandia cyanescens
Copelandia westii
Psilocybe caerulescens Murr. (Jacobs, 1975)
Psilocybe cubensis (Earle) Singer. (Guzmán, 1983)
Psilocybe mammilata (Murr.) Smith. (Guzmán, 1983)
Psilocybe tampanensis Guzmán & Pollock. (Guzmán, 1983)

Georgia

Psilocybe weilii nom. prov. Guzmán, Tapia & Stamets. (Stamets, 1996)

Hawaii

Copelandia cyanesens (Bk. & Br.) Singer. (Merlin & Allen, 1993)
Copelandia tropicalis (Ola'h) Singer & Weeks. (Merlin & Allen, 1993)
Copelandia cambodginiensis (Ola'h et Heim) Singer & Weeks. (Merlin & Allen, 1993)
Copelandia bispora Malencon & Bertault. (Merlin & Allen, 1993)
Copelandia anomala Murrill. (Merlin & Allen, 1993)
Panaeolus subbalteatus (Bk. & Br.) Sacc. (Merlin & Allen, 1993)

Idaho

Gymnopilus aeruginosus (Peck) Singer. (Stamets, 1996)
Gymnopilus liquiritae
Gymnopilus luteofius
Gymnopilus sapineus
Gymnopilus spectabilis
Panaeolus subbalteatus Berkeley & Broome
Psilocybe fimetaria (Orton) Watling. (Guzmán, 1983)
Psilocybe pelliculosa Singer & Smith. (Guzmán, 1983)
Psilocybe silvatica (Peck) Singer & Smith. (Guzmán, 1983)

Illinois

Pluteus salicinus (Pers.:Fr.) Kummer. (Gartz, 1996)

Indiana

Panaeolus papilionaceus (Gerhardt, 1996)

Louisiana

Copelandia cyanescens (Bk. & Br.) Singer. (Stamets, 1996)
Psilocybe caerulescens Murr. (Jacobs, 1975)
Psilocybe cubensis

Maine

Gymnopilus liquiritae
Gymnopilus sapineus
Gymnopilus spectabilis
Panaeolus papillionaceus (Bull.:Fr.) Quel. (Gartz, 1996)
Psilocybe caerulipes (Peck) Sacc. (Singer & Smith, 1958)

Maryland

Panaeolus subbalteatus Berkeley & Broome. (Singer, et al., 1958)

Massachusetts

Gymnopilus sapineus
Gymnopilus spectabilis (Fr.) Smith = Gymnopilus junonius (Fr.) Orton. (Pollock, 1976)
Panaeolus papilionaceus
Panaeolus subbalteatus Berkeley & Broome. (Singer, et al., 1958)

Michigan

Conocybe smithii Watling. (Stamets, 1993)
Gymnopilus aeruginosus (Peck) Singer. (Hatfield et al., 1978)
Gymnopilus liquiritae
Gymnopilus luteofolius (Peck) Singer. (Stamets, 1996)
Gymnopilus luteus (Peck) Hesler. (Hatfield et al., 1978)
Gymnopilus sapineus
Gymnopilus spectabilis
Gymnopilus validipes (Peck) Hesler. (Hatfield et al., 1978)
Panaeolus subbalteatus Berkeley & Broome. (Singer et al., 1958)
Psilocybe caerulipes (Peck) Sacc. (Guzmán, 1983)
Psilocybe liniformans var. americana Guzmán & Stamets. (Guzmán, 1983)
Psilocybe silvatica (Peck) Singer & Smith. (Stamets, 1996)

Mississippi

Psilocybe caerulescens Murr. (Jacobs, 1975)
Psilocybe cubensis
Psilocybe tampanensis

Missouri

Gymnopilus sapineus
Panaeolus papilionaceus
Panaeolus subbalteatus Berkeley & Broome. (Pollock, 1976)

New hampshire

Gymnopilus liquiritae

Psilocybin Mushrooms of the World, Paul Stamets

Magic Mushroom Dosage Calculator

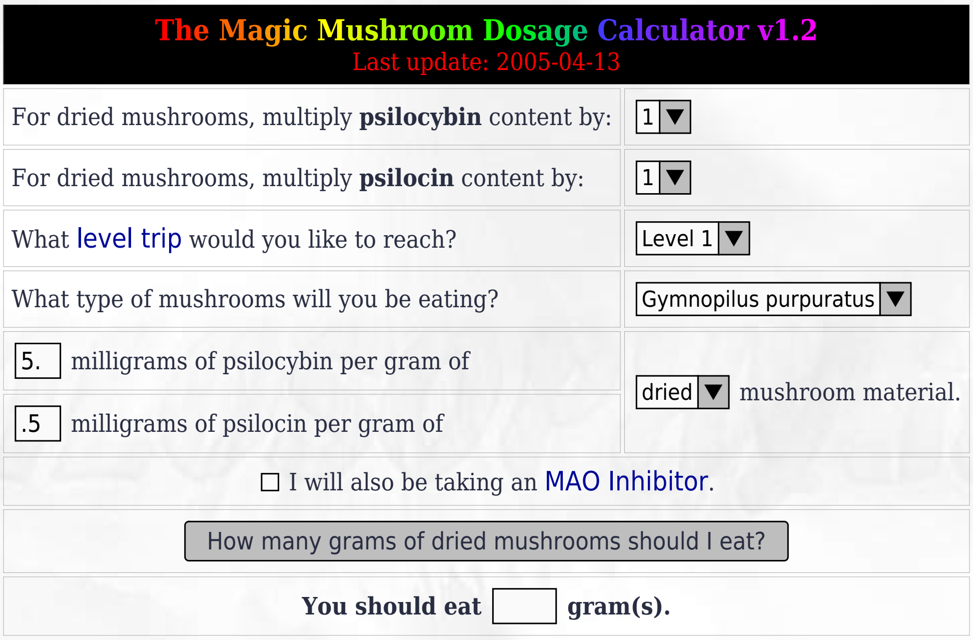
by

Ythan Burstein

original source: http://www.shroomery.org/6257/Magic-Mushroom-Dosage-Calculator

I wrote this calculator in JavaScript to help figure out how many mushrooms to eat to reach the desired trip strength. I don't have a secret unifying formula; I don't think one exists for mushrooms. I did, though, tweak a formula until it seemed accurate, and then I plugged in variables. I also left it open to user modification, so you can play with the values so it's customized to your unique reaction to the mushrooms.

Here's a rundown of what all the input fields are for; you probably won't need to modify most of them.



The Magic Mushroom Dosage Calculator v1.2
Last update: 2005-04-13

For dried mushrooms, multiply **psilocybin** content by:	1
For dried mushrooms, multiply **psilocin** content by:	1
What level trip would you like to reach?	Level 1
What type of mushrooms will you be eating?	Gymnopilus purpuratus
5. milligrams of psilocybin per gram of	dried mushroom material.
.5 milligrams of psilocin per gram of	

☐ I will also be taking an MAO Inhibitor.

You should eat ____ **gram(s).**

For dried mushrooms, multiply psilocybin content by: This allows you to specify the deterioration which the psilocybin in your mushrooms experiences when it's dried. If you suspect your mushrooms lose half their psilocybin when they're dried, set this value to ".5". If you suspect they don't lose any at all, set this value to "1". The default value is ".8", which is a median. If you take extra-special care when drying and storing your mushrooms, you'll want to use a higher number. If you dried your mushrooms by putting them in the oven at 250° for an hour, use a lower number.

For dried mushrooms, multiply psilocin content by: This is exactly the same as the psilocybin input box, only it changes the deterioration rate of psilocin. Unlike its more stable cousin, psilocin tends to break down pretty quickly no matter how careful you are about preserving your mushrooms. ".5" is the default, and unless you freeze-dry your mushrooms and store them with an industrial grade vacuum packager, you'll probably want to leave it where it is.

What level trip would you like to reach? Read the trip level descriptions and decide. You should note that it's not a straight line; if you eat 20 grams wet to reach level 2, that doesn't neccessarily mean you'll need 40 to get to level 4.

What type of mushrooms will you be eating? These are really just psilocybin and psilocin "presets". Choose the type of mushroom you'll be eating and it modifies the value of the psiloc(yb)in fields for that mushroom. The values are compiled from many sources on the internet and care was taken the values represent an average potency of many samples whenever the data was available.

Milligrams of psilocybin per gram: This displays the content of psilocybin in the mushroom you currently have selected in mg/g fresh material. If you think that the value is incorrect (and it quite possibly may be since the same species of mushroom may have up to tenfold fluctuations in its psilocybin content), you can enter a new value.

Milligrams of psilocin per gram: The same, only for psilocin.

Will you be eating fresh or dried mushrooms? Well, which kind will you be eating? If you select "dried", the Calculator applies the deterioration values to the psilocybin and psilocin content of the mushroom and compensates for the change in weight due to dehydration. Mushrooms are ~90% water when fresh, which means there will be a big difference between how much dry mushroom material and how much wet mushroom material you'll have to eat to achieve the same trip level.

I will also be taking an MAO Inhibitor. For people too lazy to divide their total by two, check this box if you take a monoamine oxidase inhibitor before eating your mushrooms.

Okay, so that's it for the instructions, but there's one last thing I want to make clear:
THIS CALCULATOR IS IN NO WAY INTENDED TO GIVE ABSOLUTELY DEFINITIVE ANSWERS!
You can have two people identical in weight eat the same amount of mushrooms, and one will trip for hours and one will hardly feel a buzz. I think the values you get by using this calculator should be pretty accurate, since I've tweaked it pretty carefully, but you should really determine your dosage the old-fasioned way, by starting small and working your way up. If you don't want to waste the time or the shrooms on that, then **BE CAREFUL** with any value this calculator spits out.

Alright. Have fun.

The following comes from here.

Level 1
This level produces a mild "stoning" effect, with some visual enhancement (i.e. brighter colours, etcetera). Some short term memory anomalies. Left/right brain communication changes causing music to sound "wider".

Level 2
Bright colors, and visuals (i.e. things start to move and breathe), some 2 dimensional patterns become apparent upon shutting eyes. Confused or reminiscent thoughts. Change of short term memory leads to continual distractive thought patterns. Vast increase in creativity becomes apparent as the natural brain filter is bypassed.

Level 3
Very obvious visuals, everything looking curved and/or warped patterns and kaleidoscopes seen on walls, faces etc. Some mild hallucinations such as rivers flowing in wood grained or "mother of pearl" surfaces. Closed eye hallucinations become 3 dimensional. There is some confusion of the senses (i.e. seeing sounds as colors, etcetera). Time distortions and "moments of eternity".

Level 4
Strong hallucinations, i.e. objects morphing into other objects. Destruction or multiple splitting of the ego. (Things start talking to you, or you find that you are feeling contradictory things simultaneously). Some loss of reality. Time becomes meaningless. Out of body experiences and e.s.p. type phenomena. Blending of the senses.

Level 5
Total loss of visual connection with reality. The senses cease to function in the normal way. Total loss of ego. Merging with space, other objects, or the universe. The loss of reality becomes so severe that it defies explanation. The earlier levels are relatively easy to explain in terms of measureable changes in perception and thought patterns. This level is different in that the actual universe within which things are normally perceived, ceases to exist! Satori enlightenment (and other such labels).

The Mushroom Entheogen - The Measure of the Mushroom

Summary

The Mushroom Entheogen explores the relationships between hard mycological chemistry and visionary experiences related to psilocybin mushroom use. In PM & E vol. 1 we were presented with optimum harvesting/storage techniques. A study of the bluing reaction with ways to inhibit its onset was presented. In PM & E vol. 2 the relationships between mushroom pretreatment agents and various forms of dehydration were presented, with emphasis on optimum psychoactivity. In PM & E vol. 4 instructions are given for constructing a vacuum dehydration system. HPTLC (high performance thin layer chromatography) comparisons were noted upon samples.

We continue this series with an overview of psilocybin potency testing - both in the laboratory and through implicit meditation and physiological / psychological observation. PM & E is exceptionally proud to bring this installment of The Mushroom Entheogen to our readers. So why do you need to test your psychedelic mushrooms for their potency?

There are two good reasons: either to see the affect of some experimental procedure on the final concentration of the active tryptamines (i.e. psilocybin and psilocin) in the mushrooms (which is pretty much what these articles are about) or more important, to know the subjective intensity of the dosage you may plan to take. You may remember the anecdote from the previous article about my friend who mistakenly took too much mushroom powder. He came very close to needing some medical help, because he thought he was losing his mind.

Neither of us had any idea that we had made a measurement error with our dose of mushrooms and he had taken twice the amount of what would have been a large dose. I ended with about half of a large dose. I was fine but he panicked and the knowledge that I had taken what I thought was the same dose made it even worse, because as far as I was concerned he was being totally irrational.

This extreme example of overdose is more likely to be the rarity. What is more common and frustrating is "under" dosing. If you are like me, a mushroom trip is a special event for which I need to plan the time. With family and job responsibilities I can no longer take a day off on the weekend anytime I feel like it. Too many times I have planned for a day of tripping only to end up with a mild buzz and a loaded feeling, not that altered state of awareness and consciousness which is characteristic of the full mushroom trip. I needed a mushroom testing procedure. Knowing what the active tryptamine concentration is before taking the mushrooms can prevent the possible problem of over or under dosing.

One aim of my research, besides reducing the toxicity of the mushrooms, is to maximize the psilocybin content of the cultivated mushrooms and to stabilize the quantity biosynthesized from flush to flush of a particular strain of P. cubensis by controlling environmental and nutritional factors. In my own research I found that as I experimentally changed these growth-affecting factors, my particular strain's concentration, as measured by the test procedure described at the end of this article, increased by a factor of four or five.

In their research, Bigwood and Beung echo this same variation in the concentration of psilocybin in the controlled cultivation of P. cubensis. But because of their large variation in what they felt was a rigidly controlled growth environment, I am inclined to conclude that they were not controlling all the possible factors which control the growth and biosynthesis of psilocybin. They found that in their own cultivation, concentrations varied by a factor of four and, even worse, specimens from other sources varied as much as ten fold.[4]

An upcoming article, using the results of the mushroom sample testing will show how, by careful control of the mushroom nutritional and environmental growth factors, one can minimize this large flush-to-flush tryptamine (the major molecular grouping in psilocybin/psilocin and other related compounds) concentration variation.

Because of even less environmental and nutritional control, this sample-to-sample variation is further exacerbated if you collect samples from the wild. Besides strain differences (i.e. genetic differences), microenvironmental and growth substrate nutritional differences contribute to large variations between specimens, even collected close together. Christiansen, *et al*. found from their studies of the psilocybin concentration of many different samples of P. semilanceata in Norway, that the content varied by a factor slightly greater than ten.[7]

If ten-fold variations exist between mushrooms of the same species, imagine the potential for variation between different psychedelic genera. Mushrooms which contain the hallucinogenic tryptamines include the genera *Concybe*, *Panaeolus*, *Psilocybe*, and Stropharia.[12] If you are collecting any of these varieties for psychedelic purposes, you may wish to consider a test of their relative strength before taking them. If you plan to take the mushrooms fresh, then with a little experience with one of the field tests described later you will be able to estimate their relative concentration. You can tell not only from the final intensity of color of the reaction but also from the speed with which the sample develops a color.

A final point on the need for a test: if you happen to be someone who buys psychedelic mushrooms, you may want to know just what you are getting for your money. Ideally, if it were legal to sell, a mushroom dealer should be aware of the relative strength of his different batches of mushrooms and should sell the dried mushrooms not by weight but by what is necessary for a moderate-dose trip.

Subjective and Objective Testing

"Okay," you say, "So maybe it would be helpful to be able to test the mushrooms I buy or grow, but I am not a chemist and I want something simple. There are two basic types of testing: subjective and objective. Subjective testing of mushrooms is descriptive. It is easy and cheap and requires only attention to one's own mind, but it does take time.

Objective testing, on the other hand, is quantitative. It is simple, usually quick, repeatable, but can in some procedures, require complex and expensive equipment. Although I have identified two forms of testing, we need both to know the psychedelic effectiveness of an unknown batch of mushrooms or to communicate what our batch of mushrooms will be like to someone else.

The problem with subjective testing is standardizing the method. Because of the vagaries of the mind, one needs to control the set and setting under which one performs his subjective testing. By controlling these two factors, although very difficult at that, one can establish a common reaction (e.g. degree of energy, quantity of hallucinations, their colors and shapes, the ease of feeling at-one with external objects or concepts, etc.) to a standardized dose. This reaction can be the gauge which one uses to compare all other subjective tests. This subjective response to a standardized dose will help one to know how much to take later.

The problem with objective testing is that no matter what value of concentration (usually expressed in mg of psilocybin/ gr. of mushroom) one finally arrives at from his test, it does not tell him what the subjective experience will be like. To know what the subjective experience is, one still needs to take the psychedelic. By doing this a few times for various concentration levels, one can extrapolate a subjective intensity value from an unfamiliar objective test value, thus dispensing with the need for subjective testing.

The advantage of having an objective test concentration value is that it can communicate what the personal experience will be like to anyone who has taken the time to compare several batches of mushrooms subjectively after finding an objective test concentration value for each batch. By comparing their experiences with a few corresponding numerical values, one can infer from a new objective test value the intensity of the personal experience when taking an unknown batch of mushrooms.

The subjective effects may vary considerably from one individual to another but it is the intensity and duration which will change linearly with the increase in the objective test value.

Subjective tests need to be done only a few times (and recorded for future comparisons) when comparing different concentration levels of mushroom strengths, after which you can rely solely on the objective test for evaluating new samples of mushrooms. Whereas, if one opts to use the subjective test only, then one will need to test each batch by actually taking a small, standardized dose. Then from this tedious evaluation one can determine the amount needed for whatever level of tripping one wishes to reach later.

Besides the problem of taking a sample dose for each and every batch of mushrooms, the subjective test has another difficulty when used alone. Its results can be difficult to communicate to someone else because the phenomenal experience may vary radically from one individual to another. For instance, someone may describe a reaction to a five gram mushroom trip as giving him a feeling of strong sexual energy with a keen awareness of his physical self.

Whereas, you may take the very same mushroom powder and even expect and perhaps look forward to a similar reaction, only to experience a very introspective trip in which the last thing on your mind is sex. The objective test value allows a means of communicating the intensity of the mushroom trip without describing the experience it evoked. By itself subjective testing has its problems, but when supplemented with objective, quantitative testing, it can become a predictive tool for us to use. And also, by itself, objective testing conveys no real meaning to us about the subjective nature of the trip. For the reason that the objective test tells us no personally valid information, one can conclude that the foundation for any quantitative test is our own subjective testing.

I have used the following procedures and guidelines in my own subjective testing. Use your own guidelines, but the primary rule is to watch the effects of the psychedelic on your body and mind. It helps to know your mind well before evaluating the changes caused by a psychedelic. The best way to understand your own mind is to regularly practice some form of mental meditation techniques in which the emphasis is on alert consciousness in an ever-increasingly calm mind.

The Subjective Test

- One can argue about the effects of set and setting on the psychedelic experience, but no matter the outcome of the argument one generally does have more physical effects, greater duration and depth of the trip with ever-increasing doses of psychedelics. Observe these differences in the trip's length and depth for different amounts of mushroom, preferably from the same mixture of mushroom powder (all properly stored so that the interval between tests does not degrade the quality of the mushroom).
- Observe your mind with little or no other sensory inputs during the trip. The best way to do this is to close your eyes or be in complete darkness, plug your ears or be in an absolutely quiet environment and lie or sit completely still. After sitting or lying like this for a few minutes, notice the intensity of the colors in the mind's eye or projected in the dark. Observe the sharpness of the edges and forms. Is the nature of the forms benign or malevolent? Do you experience dreamy hallucinations or patterns? Is your mind clear or dreamy or sleepy?
- Observe the nature of your perceptions in an eyes-open mode in a well-lighted environment. Notice the rippling effect around objects. Do you have colored patterns or hallucinations projected on the environment. This is sure indicator that you have taken a strong dose.
- Listen to sounds or music and feel their effect on your emotions and observe how they change the hallucinations or patterns.
- Observe the quality of your consciousness. Are you cloudy, sleepy, moody, willful, clear, alert? Note all

physical side effects, such as nausea, headaches, muscle aches, stomach cramping, aching joints and other uncomfortable symptoms. Many aches and pains can be a result of psychosomatic manifestations during a psychedelic trip. But many times impurities in the mushrooms can initiate the side effects, too. All the above are indications of the quality of the trip and consequently the mushroom quality. Generally, as I perfected my growing and storage techniques, the above physical symptoms diminished.
- Watch how you respond physically. How is your coordination, such as your ability to walk and talk?
- I have noticed that left brain functions - those usually associated with concrete, analytical thought processes - become harder to perform with increasing doses of psychedelics. Can you perform simple math tasks? Do you have trouble expressing ideas in speech? Can you give directions to a familiar location to someone?
- How fast does the trip come on? How long is the "rush?" How long before you start to come down from the psychedelic portion of the trip? I find that the drug effects last no longer than six to eight hours, but as I increase the dosage or strength of the mushrooms, the trip comes on faster, the rush lasts somewhat longer and the psychedelic portion gradually increases from as little as thirty minutes to as much as five or six hours. By reassessing your trip as it progresses using some of the evaluation criteria as described in the above points, you can observe the course of the trip accurately and predict its length and intensity.
- When establishing a subjective baseline for your trips, it is important to standardize the set and setting of your trip so that you minimize the results of such variables on the trip. Try to take it in the same type of environment, preferably at the same time of day. Do not take an evaluative trip if you are in a negative mood. My friend recommends jogging, or other aerobic exercises, to help elevate and stabilize one's moods.

It is best to take the mushrooms on an empty stomach during an evaluation because different foods will affect the nature of the trip. Also, having food in the stomach will slow the absorption of the psilocybin and give the impression that you had less. If you are correlating objective test concentration information with subjective intensities, make sure you always use the same amount of mushroom. I found that one gram was enough to test. It usually was not enough to put me on a full-blown trip, but was plenty to observe all the psychedelic manifestations, particularly if I closed my eyes and plugged my ears and practiced meditation techniques which I know.

Having evaluated your mushroom samples subjectively, you are well on your way to being able to plan for an entheogenic, or ecstatic trip because you know how much to take for the sought-after experience. The emphasis of these articles is purposely limited to the use of the mushrooms for the more introverted and spiritually expanding psychedelic experience. True, many of the preparation, growing techniques and even some of the suggestions for directing the energy of the experience (a later article) can apply to trips which focus on interpersonal relationships or even for those who just want to have fun for an afternoon, but you will not need to work as hard for these non-entheogenic experiences. My background with psychedelics, and primarily with the "magic mushrooms," has shown me that the highest quality mushroom experience and states of consciousness come with effort and planning between trips and a tremendous burst of yearning during the actual trip.

Apparently a change in consciousness takes effort and time. The more intense the concentration of effort and desire for such a change, the faster is the change in consciousness. The next section may be superfluous to your needs if you are not drawn to such objective evaluation of your mushrooms. But even if you do not elect to do any chemical testing of your mushrooms the discussion might help you to understand the meaning of the values which I will describe in upcoming articles on environmental and nutritional influences on the growth and psychedelic tryptamine production in P. cubensis. So I encourage you to read at least the general theory and interpretation of the test's results. The actual test procedure is at the end of the article for those who wish to do their own chemical evaluations.

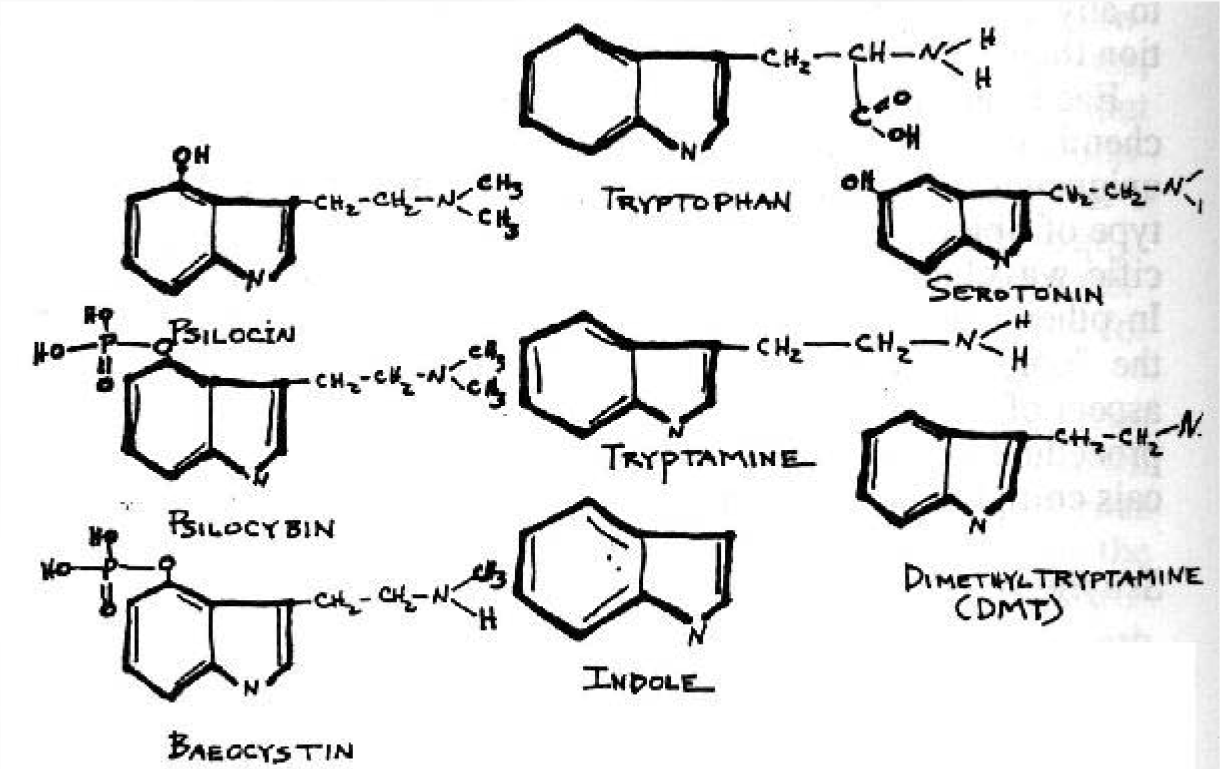
Objective Testing

General theory and various detection and measuring schemes

Objective test results can give a numerical value which tells how much, and for some tests, what is in a mushroom. One can find a relative concentration value or an absolute concentration value. If one has access to the pure psychedelic tryptamines then one can derive the absolute concentration by measuring an accurately weighed amount of the pure sample and then comparing that test result with the value obtained for the unknown sample. If one does not have a pure sample it does not matter because the numerical test results will indicate that one sample has more of the measured tryptamine than another and to what degree it has a greater concentration.

These numerical or objective test results greatly help communicate the relative strength of different batches of mushrooms to any one else who may have a different subjective interpretation than yourself. Each individual chemical behaves differently from all other chemicals because of its unique structure. Based on this uniqueness of each chemical, objective tests are possible. One type of objective testing relies on the unique absorption of specific wavelengths of light absorbed by each unique chemical.

In other words, each chemical has a different color, although the "color" is usually not in the visible spectrum. Another aspect of each chemical which is often used in designing a test procedure is that it will interact with or react with other chemicals completely differently.



INDOLE—TRYPTAMINE DERIVATIVES

Figure 1 - Shows indole-tryptamine derivatives. Similarities between naturally occurring bodily compounds and hallucinogenic compounds allows for the psychedelic effect.

Tests can be developed which are also based on the similarity of various compounds with the understanding that a related portion of the molecule will react similarly. For instance, there are several active molecular components in the entheogenic mushrooms but the most important component includes the general family of molecules, called tryptamines. All these tryptamines have in common the indole ring in their molecular makeup. Tests have been developed which show whether this indole ring (as part of the larger tryptamine molecule) is present in a solution and to what degree.

The several different types of tests which are available to the scientist include spectrophotometry, colorimetry and chromatography. Spectrophotometry measures the degree with which the molecule under investigation absorbs light at specific wave lengths. But because most organic molecules absorb best in the infrared or ultraviolet spectrum and these instruments are expensive for the average hobbyist, I have not pursued these techniques.

Chromatography is a technique which separates mixtures of compounds by passing the mixture while in solution through a specially prepared media (the "sorbent") of highly refined sand, called, "silica gel." Silica gel is the most common sorbent used, but other less common sorbents can be used. The mixture of various molecules interact differently with the molecules on the surface of the silica gel as they pass and thus slow their movement to a greater or lesser degree.

After migrating through the silica gel for a distance, the mixture of compounds segregate into separate bands of pure compounds. Chromatography generally falls in two modes, depending on the apparatus used with the silica gel to separate the sample - thin layer chromatography (TLC) and column chromatography of which high pressure liquid chromatography (HPLC) is another technique subgroup commonly used in the lab.

As the name indicates, in TLC a thin layer of silica gel is applied to a glass or plastic plate then the sample is streaked or spotted near the bottom of the plate. The plate is then put into a glass tank in which a small amount of a particular solvent mixture, determined by experimentation, has been poured. The silica gel, being porous, allows capillary action to draw up the solvent which pulls the sample, too. As the sample moves each pure chemical in the mixture moves at a different rate thus causing a separation into bands of the pure component molecules of the sample mixture. Different techniques are available to make each pure chemical band visible.

Figure 2 - Shows a rendition of the TLC (Thin Layer Chromatography) processing. This method of visual analysis allows chemical present within the mushroom to be compared next to one another.

For a given sorbent and solvent a particular compound (e.g. the psychedelic tryptamines) will always move up the TLC plate the same relative distance when compared to the distance that the solvent was allowed to creep up the plate. For example on one occasion a researcher let the solvent develop on the TLC plate for one hour and the solvent moved up the plate 10 cm. After using either a chemical dye to detect the chrometegraphed spots or a UV lamp, he found that the spot he was most interested in moved 5 cm up the plate or half way between the starting point and the solvent front. On another occasion he only let the plate in for 45 minutes and the solvent moved only 8 cm. Because he knows the compound has an Rf (an abbreviation referring to relative migration distance up a TLC plate of a pure compound) of 0.5, then under identical conditions for the same chemical, the spot of interest will move half way up the plate or 4 cm. And so it does in practice.

The experimental literature will usually have these relative distance values for most compounds, which are always less than 1.0 (An Rf of 1.0 would indicate that the compound moved with the solvent all the way up the plate; therefore its relative distance when compared to the distance that the solvent moved is 1.0.) After a TLC separation it is easy to see if a particular compound is present by looking for a band which occurs at the correct distance up the plate. The intensity of the color of the band will indicate the concentration of the compound, or one can actually scrape the band off the plate and measure the nearly pure compound by some of the other techniques available.

HPLC (or High Pressure Liquid Chromatography) is a form of column chromatography. The sample is applied at the top of high pressure capable column with sorbent in it, then the solvent is pumped through the column at high pressures (usually 1000 psi or greater). At the other end of the column a spectrophotometer monitors the solvent for an absorbance which indicates an organic compound is coming off the column. The experimenter can view the output from the spectrophotometer via a graph output or a video screen.

The area under the peaks which represent each different molecule are proportional to the concentration. With samples of the pure tryptamines, one can calculate the absolute concentration of the compounds investigated. An HPLC solvent is pumped through the column until most of the sample has been washed off. Instead of distance traveled through the silica gel as in TLC, the time it took to wash the compound off the column before it was detected by the spectrophotometer is used to determine what the molecule is.

If you read the technical literature you will see HPLC mentioned often. Its advantage is far greater sensitivity and ability to resolve many more compounds which may be present in an unknown sample. Its disadvantage is cost. The average HPLC set up may cost $10,000. Whereas one can buy pretty much all he needs to perform TLC for about $100 to $200.

Which brings us to the last general detection technique and the one of choice for most of my research - colorimetry. Colorimetry is similar to spectrophotometry in that a solution of the sample absorbs specific wavelengths of light and the wavelength and the degree of absorbance can tell much about the sample. But in colorimetry the light absorbed and the consequent color of the solution measured falls within the visible spectrum. Also, because the absorption peaks cover a much broader range of wavelengths than in the ultraviolet (UV) or infrared (IR) regions, the spectrophotometer used can be much less sensitive and can use coarser methods of breaking up the light spectrum to irradiate the sample. The instrument used for colorimetry is called not a "spectrophotometer," but a "colorimeter" and can use filters rather than the much more expensive diffraction grating monochrometer used in spectrophotometers.

The trick with colorimetry is making the sample molecule which normally does not absorb in the visible spectrum (i.e. 400 to 700 nanometers, which is the wavelength of light from the deepest reds to the faintest violets) visibly colored. Chemists have found that there are molecules which by themselves are uncolored but when combined with certain other molecules will form a color. These chemicals are called "chromophores" and the presence of this color indicates that the molecule under test exists in the solution and the intensity of the color tells one how much of the compound is in the solution.

The problem with colorimetry is that most chromophores do not combine specifically with a unique molecule but with a portion of the molecule under test. For example, in the test which I used in my research, the chromophore reacts with the indole ring of the psychedelic tryptamines to form a blue or purplish color. Indole rings are not specific to psychedelic tryptamines. There are many molecules other than the psychedelic tryptamines which have indole rings.

And to further complicate things, the chromophore will react with other nitrogen containing centers, although without the usual blue or violet color. The net result can be a hodgepodge of color which overlaps to a greater or lesser degree with the specific wavelength, or color, which the colorimeter is viewing. The colorimeter is dumb; it does not know the difference between an absorbance at 570 nanometers which is caused by urea or psilocybin or a little of both. Generally, the non-active compounds have absorbances far enough away in the light spectrum so that they do not interfere with the psychedelic tryptamine readings, but this is not always the case. I will discuss this interference and how it relates to the interpretation of the test's results in a later section.
